Costs in Mining.

Comparison of costs in operating mines in different districts of the same country is not always satisfactory, and how much less so must a comparison be of regions widely separated, as, for instance, the Rand, in South Africa, Western Australia and the Western United States. The latter furnishes almost every conceivable condition—good, bad and indifferent. The mines of the Rand are not dissimilar as a whole, yet the cost of operation at various mines in that region varies with the width of banket, the greater or less amount of water encountered, and the arrangement and capacity of the surface equipment. In any region a large mine should usually be operated more cheaply than a small one, the cost per ton being the unit of comparison. In America the mines of the Rand have their nearest type represented, structurally, in the Lake Superior copper mines, and yet the costs per ton in the two regions are widely different. The ores on the Rand contain, generally speaking, about $10 per ton; those of the Lake Superior copper mines range from $5 to $10 per ton, fluctuating with the copper content of the ore and with the market price of the metal. At the Calumet & Hecla 6000 tons of ore are treated daily. The largest tonnage of any mine on the Rand does not exceed 1800 tons. The climatic conditions are wholly different, and comparisons cannot be justly made.

In Western Australia the conditions are essentially similar over a large district—an arid desert without natural fresh water. Wages are high and white labor is employed almost exclusively. Water—furnished by the great system recently completed by the Government—is expensive, and a comparison of costs in that section with those of other regions is not satisfactory, no matter what these figures may indicate. Mines may be operated under favorable conditions in California more cheaply than similar mines under the adverse conditions of the deserts of Arizona or southern Nevada, or the mountain regions of Mexico. The enterprise of the people of Colorado has built railroads to many important districts, and the mines thus favorably located are worked at less expense than those less fortunately situated. These comparisons may be continued to great length, but attention has been called to some of the important mining regions, and it is evident that what is first-class and economical work in one region might be considered as extravagant in another, where the conditions favored the operators and made cheaper methods possible.

Steel Head Frame at Gwin Mine, Calaveras Co., Cal. (See page 5.)

The fairest basis for comparison lies in the methods of different managers of the same property at various times. Some successful managers have made reputation and fortune by being sent to take charge of a property where nothing was being properly done, where all was chaos, where the work accomplished was not nearly commensurate with the number of men on the payroll. The experienced manager is quick to see and change all this. He either promptly cuts down the force to its normal capacity or keeps the force and increases the output without increasing the expense. This is called good management, but there are several degrees of good management as well as of that which is poor, and bad—and occasionally villainous. A man may build up a reputation as a good manager and yet be succeeded by another who will find opportunities to change the methods in vogue for those that are better. Changes in metallurgical processes, due to constantly increasing knowledge, also make it possible to cut down working costs. In short, when studying the cost sheet of some important mine situated at a distance, in order to appreciate the relative merit of the expense of working as compared with some other mine in another part of the world, it is necessary to know much of the conditions under which each operates. Mining costs are influenced to a great extent by the size of the deposit, character of the ore, and of the wall rocks. These conditions determine the methods of mining and timbering. The water problem must be understood, the rate of wages and efficiency of labor is important, and the cost of hoisting varies with the capacity of hoists, distance hoisted, cost of power, etc. Reduction of the ore is equally variable. A free-milling ore should generally be cheaply treated, even in a small mill, while a refractory ore is expensive to reduce in a mill of any sort. Smelting, like milling, is variable as to cost, depending on situation, transportation, character of ore and capacity of plant; finally, the management—it may be as good as can be obtained or it may be bad, with several shades of variation between the extremes. Thus it may be seen how difficult is a just comparison of the costs of mining and treatment of ores in the various mining regions of the world, without an absolute knowledge of the conditions obtaining at the places under consideration.

One of the most important factors in the cost of mining is the efficiency of labor employed. It is not apparent that because a man works for a relatively small wage that he is a cheaper man than he who demands and receives a higher sum for his services. A man may receive $4 per day and accomplish double what two other men may be able to do who are each paid $2 per day. In such an instance it would be wrong to call the $2 man the cheaper, when in fact he is the more expensive. It is true that in some instances it is entirely a question of taking whom you may get in order to secure laborers sufficient to operate at all. This has practically been the case in the mines of the Rand for some time past, with little prospect of immediate relief in that direction.

The Kaffir laborer has proved efficient—when efficiency is compared with the wages paid him, but the great difficulty in getting a sufficient number of the natives has caused the managers to seek elsewhere for men, and China is now looked to as a probable source of supply. Chinese labor will be cheap, but the mining methods of the Rand are totally different from those in vogue in China, and these Asiatics must necessarily be educated to the work, besides which, many of them in all probability will never have seen a mine before. The influence on cost of this new situation in the management of the gold mines of the Rand will be a study in the economics of the industry, but at the same time it is apparent how unfair a comparison of costs would be, when considered as indicating the character of the management, which is placed in an unfortunate position.

Assessment Work in Alaska.

A petition from Alaska memorializing Congress for the purpose of securing legislative enactment suspending the necessity for annual assessment work has been presented to several Senators at Washington. The reasou given for such a step is stated to be the great cost of living, difficulties of transportation and the short season in Alaska, in consideration of which the memorial asks that annual work be suspended until the country is settled up. Such a request from almost any other mining section of the United States would have caused less surprise than one coming from Alaska, where the richness of the mines and the comparative ease with which the gold is obtained, judging by the output of the past few years, has led the mining world to think that Alaska was not the least favored of the mining regions of America. Such a law as that asked for would do more to retard the development of that wonderful north land than the most rigorous of winters, and would permit the wholesale taking and holding of mining claims without representation for an indefinite period. The argument employed, that as the United States derives no revenue from the performance of the required assessment work, the petition should be granted, is weak, and, in fact, no argument at all. Alaska's mineral resources would uot be promoted by the passage of such a bill as contemplated. Moreover, in consideration of the large amount of gold annually coming from the mines of Alaska, it is evident that the short season, expense of living, etc., form no substantial obstacle to the development and operation of the mines of that Territory.

A GREAT deal is being said and written about mine gases aud their composition. All mines are subject to the accumulation of gases of one kind or another, but the simplest way to deal with the problem is to afford complete ventilation with abundance of fresh air from the surface.

Legitimate Speculation.

The uncertainty in mining is always a pronounced feature in the exploration of a vein when no ore is in sight, and the search for it is being prosecuted on general principles, as it were, in the belief that existing geological conditions warrant such exploration. When day after day and month after month passes and the search continues without reward, those who are paying for this experiment in time begin to feel discouraged, and they eventually will quit, and often, as is subsequently proven, just on the verge of success. The Gladstone mine of Shasta county, California, is one of the most recent examples of this experience. Some years ago an Eastern company operated the mine but failed to find anything of payable value, which fact, coupled with legal troubles, led to the closing of the mine. The original owners did several thousand feet of exploratory work, but without success. After several years of idleness a new company took the property, cleaned out the old workings, drove the main drift about 130 feet ahead and struck a fine body of ore. This instance was not altogether fortuitous, for the geological conditions indicated the probability of the proximity of an ore deposit, but the former owners discontinued work too soon. To hopelessly drift and crosscut through a barren country rock where there is no known ore in the vicinity, and no indication of ore, would be the height of folly, but to thoroughly explore a mineral vein in a mineral country in the belief or hope of finding payable ore is legitimate, and such course is often rewarded with success. It was this spirit that developed the "Big Bonanza" in the Con. Virginia and California mines on the Comstock in the early '70's. It remained an undeveloped block of ground between two mines of proven value. The operators assumed a great risk in undertaking the development of this block of ground, but their faith in conditions which to them seemed proper for the production of a mine was rewarded with success. There are many places in the mining regions of the world where such systematic exploration is justifiable, but the great risk which is a natural accompaniment of such undertakings deters the cautious investor from engaging in an enterprise the outcome of which is so uncertain, but there are frequent examples of satisfactory results from just such ventures. Colorado is full of them, and so is any country or district where the leasing system is followed to any extent. Leasers usually have to take a mine with nothing in sight, and explore for new bodies of ore.

The Development of Africa.

The eyes of the civilized world are directed toward Africa, and much that is good is expected to come out of the central portion of the "Dark Continent." The borders have been explored and are fairly well known, particularly along the Mediterranean and in the south portion of the continent. The phenomenal output of the gold mines of the Rand and of the diamond mines about Kimberly has done more to attract the attention of capital to Africa than anything else. The climatic conditions are such that Americans and Europeans can live in that country in comfort; but the vast wilderness of Central Africa drained by the Congo and its tributaries and by the Nile is most unhealthy, and exploration and development of that region must necessarily be slow. Still it is progressing. The early explorers—Livingstone, Stanley, Speke, Grant, Parke and others—sent out occasional fragmentary reports of the occurrence of mineral in that wilderness; but it is only within the past ten years that more than passing attention has been given it. It is known that large bodies of iron ore exist in numerous places, and Katanga, in the southeast portion of the Congo Free State, which for years has been reported to be a copper country, is now known to be rich in that metal. English capital is exploring the deposits of Katanga and developing some of them. Immediately south of that section is the British colony of Rhodesia, in which are known gold and copper mines. It is even said to be the original "land of Ophir" mentioned in the Bible, and the finding of ancient workings of mines and metallurgical establishments lends color to the idea. About the old native village of Tete, on the Zambezi, there are gold deposits aud gold-bearing veins, and Livingstone wrote over thirty years ago that the hills about Tete everywhere showed evidence of extensive alluvial washings for gold, which could still be obtained in the gravels. Along the west coast gold mines are being developed under extreme difficulties, owing to severe climatic conditions, but the history of mining in the past has shown that white men will penetrate any country and face any hardship for gold. What Africa requires to promote its development is railways, and the signs indicate that within the next decade Africa will have an important system of railroads, and its natural resources will be brought to light.

Efforts to Control Zinc Output.

The zinc miners of the Missouri district in their endeavor to regulate and sustain the price of spelter have curtailed the working days of the miners, and as a result it is stated that more than 1000 miners have left that district seeking a field where steady employment may be secured. It appears to be a question of expediency whether the mines be worked single shifts, with smaller number of men, or to suspend operations entirely at stated times for a period, the object being to curtail output, in order to raise and keep up the price. It is suggested by some of the operators that the curtailment of output begin in September of each year and be continued for several months.

Any scheme to lessen the output would accomplish the desired result were Missouri the only zinc-producing region in America, but within the past year a notable change has taken place in this industry. Mines which had been idle for years have been reopened, and owing to better mining methods and improved means of transportation these mines can now operate profitably. In addition to this, the advent of the electro-magnetic separator has brought the precious metal mining districts into the zinc market as a prominent factor in production. Of these, Colorado, Idaho and British Columbia are the principal producers. In former years the zinc ores of these districts were in some instances rich enough to be shipped direct to zinc smelters, and were a source of profit. All ores too low grade to ship as straight zinc ores were either sent with iron and lead to the lead smelter, where they were charged an arbitrary penalty per unit (variable at the different works) for all zinc over a given amount, or this class of ores was thrown on the dump or left standing in the mine, as too low to pay. The electro-magnetic separator has changed all this, and now the zinc in those ores, once a drawback to their treatment, has become a profitable by-product, while the iron and lead from which the zinc has been separated are in demand at the smelters.

Not only is this the case, but the known extent of the zinc field in the Missouri-Arkansas region is being almost daily extended by new discoveries. The newspapers weekly chronicle new finds of zinc ore on farms outside the recognized limits of the field, and new zinc mines are being opened up in unthought of places. All of this shows that the production of zinc is on the increase and the matter of its control by the operators who are so widely separated becomes daily more difficult of accomplishment.

THERE is much difference of opinion on the Rand, South Africa, whether it is profitable to concentrate pulp from the stamp mills before cyanidation or not. There is a tendency to direct cyanidation of sulphurets, and in some instances in the United States it is successful. Direct cyanidation of sulphurets has also been successfully accomplished in Korea. This method is said to be more satisfactory in the treatment of low-grade sulphides than those which are rich, presumably because, while the percentage of extraction may be about the same in either case, the loss in the instance of high-grade ore would practically prohibit its employment. Fine grinding has demonstrated that a high percentage of value may be extracted from rich sulphides, and also from that caught on canvas tables. It then becomes a question whether the higher extraction obtainable by fine grinding admits of a profit over the cost of reducing sulphides to a fine state. In most instances it is probable that the increased extraction would more than pay the expense of grinding if proper mills were employed for the purpose.

CONCENTRATES.

THE approximate pressure on a board 1 foot square, held perpendicularly in a stream flowing 3 miles per hour, would be 0.129 pound.

✣✣✣✣

IT requires about 50% more water to start a hydraulic elevator than is required to keep it running after it is started. Lack of knowledge of this fact is responsible for occasional failures of hydraulic gravel lifts.

✣✣✣✣

THE rock specimens from Bridgeport, Cal., are obsidian and vitrophyre, two varieties of volcanic glass. They are of no commercial value. The former is often shaped into arrow and spear heads and other implements by the Indians.

✣✣✣✣

WHERE assessment work has been done on an unpatented claim this work will stand whether the same was paid for or not, this being a private matter between the claim owner and the person doing the work, who has recourse in law if he fails to get his pay.

✣✣✣✣

THE cause of the leakage of the blow-off valve in the steam boiler is probably due to scale or mud getting in between the valve and its seat and grooving one or both parts. An immediate test for leakage there is necessary, the pipe to be disconnected and the valve plugged.

✣✣✣✣

THE "cut-rate" broker and the knocking blackmailer are closely allied, and small partitions do the bounds divide, in the case of offering treasury stock for sale at a less price than that announced by the company or its authorized agents, where the company is thus trying to get money enough to do necessary development work.

✣✣✣✣

ORES containing gold, which are to be roasted for chlorination treatment, are usually roasted without addition of salt in the furnace, owing to the heavy loss of gold by volatilization when salt is added. The ore is given a thorough roast, and the chlorine treatment is introduced later in a vat or barrel, according to the process employed.

✣✣✣✣

ALMOST entirely California oil has an asphaltum base, though there are localities that report oil with paraffine base. It is possible to refine oil having 40% asphaltum. The asphaltum in the California oil is a product peculiar to that State, and is not viewed as a defect or disadvantage. Asphaltum is of great industrial value and will find extended use.

✣✣✣✣

THEORETICALLY—and, in fact, usually—in case of a shaft connected with a tunnel, the shaft is an upcast, but there are exceptions. Some instances are known where during the winter months a shaft so situated is an upcast, and during summer it is a downcast. Other cases have been noted where a shaft was downcast during the day and upcast at night.

✣✣✣✣

GABBRO is not generally recognized as a gold-bearing rock, though sometimes forming the wall of a vein, in which case gold might possibly be found in the gabbro as the result of infiltration from the vein. Schists which have been altered from diabase or diorite not infrequently carry gold when associated with gold-bearing veins, and sometimes from zones of ore of value.

✣✣✣✣

SCHEELITE is a calcium tungstate. It is a heavy mineral, gravity 5.9–6.1; hardness, 4.5 to 5. In luster it is vitrious; color, white, pale yellow, brownish, greenish, reddish; streak white; from transparent to translucent; tungsten trioxide, 80.6; lime, 19.4. Molybdenum is usually present. Tungstic acid occurs in combination with numerous minerals, viz., iron, lead, copper, etc.

✣✣✣✣

THE obligation to perform the annual assessment work on a mining location ceases upon the final entry at the land office. That is when the money is paid and receipt is issued therefor, for the land then ceases to be a part of the public domain, and becomes the absolute property of the one applying for patent. Mill sites are not subject to the annual assessment law, as a mill site is presumed to be non-mineral.

✣✣✣✣

THE beach sands on the north coast of New South Wales, Australia, near Newcastle, are said to contain gold, 18 ounces per ton; platinum, 244 ounces per ton; osmiridium, 30 ounces per ton; cassiterite (tin oxide), 65%; monazite, 5%. The sands had been carefully concentrated before the analysis was made. The sands are concentrated in sluice boxes. The valuable minerals are described as being in a very fine state of division.

✣✣✣✣

LEAKS in concrete can be stopped with linseed oil. Where large cracks occur they may be filled with cement grout and the linseed oil then poured in as long as it is absorbed. There is formed in the crack a gum from the oil, which ultimately fills it to the top, after which the entire surface may be coated with successive applications of the oil until it ceases to be absorbed. Where there is a large fissure it were well to first fill it with asphalt.

✣✣✣✣

THE International Nickel Co.'s nickel mining property is, mostly, at Copper Cliff, near Sudbury, Ontario, Canada. It is an open quarry proposition at the mine, the pyrrhotite and chalcopyrite averaging 2% copper and 7% nickel. The ore after roasting requires about one-sixth of its weight of coke for smelting. The matte, after smelting, consists of about 17½% copper, 17½% nickel, 25% to 50% iron and about 25% sulphur. The low-grade matte is re-treated at the Canadian works, but for the final separation of the copper and nickel it is sent to the New Jersey Refining Works, where pure nickel is produced.

✣✣✣✣

THERE is a difference between abandonment of a mining location and forfeiture. Abandonment is intentional neglect to comply with the requirements of the law regarding annual assessment work, and is considered as evidence that the locator no longer thinks the location of sufficient value to warrant assessment work. He may believe the location valuable, but neglect to comply with the law. This makes the claim liable to forfeiture.

✣✣✣✣

RUBY SILVER is of two kinds, arsenical and antimonial. Pyrargyrite (dark red silver ore) contains sulphur 17.8; antimony, 22.3, and silver, 59.9; luster, adamantine; color, black to grayish black, and, by transmitted light, deep crimson; streak, purplish red; transparent in very thin splinters. Pronstite is light red silver ore; sulphur, 19.4; arsenic, 15.2; silver, 65.4; luster, adamantine; color, scarlet-vermilion; streak same as color; transparent to translucent. These ores occur with the other ores of silver in the sulphide zone.

✣✣✣✣

PROSPECTORS are sometimes misled in searching for the source of placer gold, when on finding a vein near at hand, apparently the source of the gold found in the placer, they find the quartz contains no gold. Sometimes the gold is in the wall rock and not in the vein at all. This is particularly the case with some pocket veins where the gold is found in the walls in connection with seams which intersect the main vein. There are numerous examples of this in Calaveras, Tuolumne and Mariposa counties, Cal., as well as elsewhere.

✣✣✣✣

IN the case of co-owners of a mining claim the assessment work must be fully accomplished. A partial performance of $100 worth by one of the co-owners will not save the claim, and for this reason one co-owner to save his own interest may be required to do more than his share, but the law provides a remedy for such cases if the co-owner who fails to do his share of the work also refuses to pay his share of the expense, but the burden of proof rests with the co-owner endeavoring to dispossess his co-owner on the grounds of forfeiture for failure to do or pay for his share of the assessment work.

✣✣✣✣

THE best way to treat a "low plate in a shaft," by which it is assumed a low timber is meant, is to remove the low plate and substitute another placed in the proper position. A low timber in an inclined shaft is a great menace to the lives of men required to pass it in going up and down the shaft on skips and buckets. In the case of enlarging an incline shaft from a smaller to a larger compartment, where the shaft is made higher, great danger may be avoided by making the change gradually, extending it over three or four sets, and planking that portion to avoid the likelihood of a man being injured while passing that part of the shaft.

✣✣✣✣

CHALCOCITE (copper glance) is a high-grade copper sulphide, containing when pure 79.8 copper. It is supposed to be of secondary origin, being the result of redeposition of copper leached from lower grade ores at a higher level by escending surface waters. The phenomena is not fully understood. This ore constitutes a large part of the high-grade ore of the Butte district, Montana. Chalcostibite is also a result of secondary enrichment, and consists largely of copper, sulphur and antimony, with some iron. In the Butte district this ore occurs sparingly, and carries as high as 1500 ounces silver per ton. It is known as copper-antimony glance. It also occurs in copper mines of Spain and at Wolfsberg, in Germany.

✣✣✣✣

REPLYING to a query from Custer City, Idaho: The only court decision having an apparent bearing on the case as stated is that of the case of Elder vs. Horseshoe M. Co., S. D., 87 N. W., 586, in which the Supreme Court of South Dakota said as follows: "We feel justified in the conclusion that Congress, in adopting the provisions in regard to the disposition to be made of a defaulting co-owner's interest in the claim, acted upon the same theory, and the published notice was intended to accomplish the same result as the published notice for application for patent; that is, to cut off the claims of all persons, and vest in the co-owner a clear title to his co-owner's interest, without regard to minors, lien holders, or incumbrances."

✣✣✣✣

"GRUB STAKE" contracts are not within the statute of frauds and do not require written contracts. They come within or partake of the nature of "qualified partnerships." These contracts are usually in the nature of a mutual understanding wherein one party furnishes the provisions, tools, etc., for a prospecting venture for a half or other stipulated interest in anything that may be found by the other. The outfitter must perform his part of the contract as a condition precedent to sharing in any discoveries. Should the prospector discover anything of value a community of interest is at once established, and the outfitter cannot be deprived of his interest. If the contract contemplates the development and operation of any mine that may be discovered then the contract becomes a partnership. In the absence of this detail of the contract neither partner to a "grub stake" arrangement can be compelled to join the other in development and equipment of the property. They are simply tenants in common, neither party having a right to bind the interest of the other.

✣✣✣✣

REPLYING to a question from "Hydraulic Engineer:" The situation as stated seems unfortunate, as the quantity of water apparently available is but 1050 gallons per minute, equal to about 88 miner's inches. A hydraulic elevator has been shown by experience to work well on nothing less than a 7-inch throat, and this requires 70 miner's inches, leaving only 18 inches to sluice with. If a reservoir could be created in the gravel deposit, a dredger might be more satisfactorily employed to handle the gravel, the pump as in diagram A being only required to lift the water to the reservoir. Either of the plants as described in the diagrams would be of too limited capacity to make hydraulicking profitable owing to low efficiency of water employed.

✣✣✣✣

A RUBBER HOSE, made for steam use, can be attached to a mine pump, and makes it possible to lower or raise the pump without disconnecting, if a slip joint be used on the column pipe, and the exhaust be carried into the sump. The hose, however, will vulcanize with the heat and become brittle. Another drawback to its use is due to the leaking of the joint at the couplings. If the steam be kept in the pipe constantly these joints will remain tight, but if allowed to cool the joints will leak, and it is almost impossible to make them tight again owing to the vulcanizing of the rubber. A slip joint on the steam pipe is advised, as it obviates all of the difficulties above enumerated as incident to the use of steam hose. The column pipe should be connected with flange joints, as it makes their removal much easier of accomplishment, and also affords a good means of supporting the pipe by means of yokes.

✣✣✣✣

THE dry placers of Western Australia greatly resemble some of those found in the arid regions of the southwestern United States. In both of these regions the gold has been derived from outcropping veins, which together with the enclosing rocks were disintegrated into particles ranging from coarse sand to dust. The wind blows the lighter portions away, leaving only the coarse material on the surface, and in this debris, the result of the surface decay and degradation of the rocks, the gold is found. Often the pieces weigh several ounces. In a few districts thousands of dollars have been picked up from the surface of the ground, as on Rich hill, near Wickenburg, Arizona, and at Pipendero in the Cargo Muchacho mountains of California. In some localities a conglomerate forms of this surface debris, in which the cementing material is carbonate of lime, and this is also often gold-bearing. The gold is recovered from the sands by various kinds of dry-washing devices, the most primitive of which is a pan or batea, or a blanket in which the sand is placed, and tossed into the air during a strong wind. The result is the fine material is blown away, only the coarser and heavier particles being left, and with them the gold, which is picked out by hand. The dry washing machines work automatically, the operators supplying the power and feeding the machine with alluvial. These machines are of numerous types, but all operate on the same principle—the sorting power of a gust of air, which is created intermittently while the machine is shaken from side to side to keep the sand in motion. The amount of material two men can handle daily depends upon the character of the alluvial and kind and size of the machine and also on the vigor of the operations.

✣✣✣✣

THE several rock specimens from Chelan, Wash., are country rock—that is, are not vein rocks or ores, but the kind of rocks which go to make up the general formation of a mountainous country, and are all either metamorphic—that is, rocks which have been changed from their original condition to their present crystalline form—or they are intrusive dike rocks. They may be described as follows: No. 1, a dike rock with small veinlets of quartz; No. 2, actinolite, a calcium-magnesium-amphibole; No. 3, feldspar, quartz and mica, and is apparently from a pegmatite dike or vein, (pegmatite is a coarse-grained granite); No. 4, sericite schist, with small garnets (evidently altered granite); No. 5 is mica schist (metamorphic); No. 6 is much altered, but is apparently mica-andesite, an eruptive rock; No. 7 is black amphibole (bornblende), a constituent of many metamorphic and eruptive rocks; No. 8 is much decayed, but consists chiefly of mica and kaolinized feldspar stained with iron oxide, possibly altered, decaying granite; No. 9 is a variety of silica called opal and may be a silicified wood, many specimens of which it resembles; No. 10 is orthoclase (potash feldspar), a constituent of granite; No. 11 is talc schist, evidently the alteration of a greenstone of some sort; No. 12 is very much altered; the feldspar is kaolinized, but was apparently orthoclase; the green mineral in it is chlorite, probably altered from hornblende; this would indicate that the rock was originally syonite; No. 13 is an altered granitic rock, possibly aplite; it is much decayed. None of these rocks are recognized carriers of mineral, though No. 11, if accompanying a mineral vein, might carry gold, as wall rocks of that sort sometimes do. No. 13 may also possibly be gold bearing, particularly if it becomes more siliceous. Neither 10, 11 or 12 are suitable to make bricks. No. 13 might be utilized for building stone, if the walls were not built too high, as the stone is not very firm in its present condition, judging by the specimen sent.

Development and Operation of a Mine.

Written for the MINING AND SCIENTIFIC PRESS by W. H. STORMS.

NUMBER II.

The benching methods employed at the Mount Lyell copper mine in Tasmania were described in the first paper of this series. At that mine an amount of overburden, estimated at 3,000,000 tons, has been or is being removed and dumped on either side of the great open cut. The cost of the removal of this waste rock is placed at about 50 cents per ton. In the future it will, no doubt, become necessary to work the large ore deposit at this mine by underground stopes, as has been the case eventually at almost every large mine at some time in its history, and when this time arrives at the Mount Lyell mine these great dumps of waste can be utilized for filling the stopes, but undoubtedly it would be a better, and more economical plan, to have underground stopes under way in order that a large portion of this overburden might be used as it is broken, and thus avoid the expense of rehandling, beside greatly reducing the first cost of its removal to the sides of the cut. This indicates the necessity of foresight, and emphasizes the fact that a large and profitable mine is not always conducted on the most economical basis. In reduction methods the Mount Lyell excels, but their mining methods are evidently the result of existing fortunate conditions. As there is a very large tonnage immediately available, it is seemingly not deemed necessary to anticipate the future to so great an extent as here suggested.

At the Mount Morgan mine, in Queensland, Australia, at one time large underground stopes were made (above drainage level) which were timbered by the square-set method, and these stopes were filled with waste. Subsequently the system of ore extraction was changed and great surface cuts were opened, which now expose the sets constructed in the underground stopes. The large open cut of the Mount Morgan mine, illustrated on page 420, explain the existing condition better than a description could do. Much of the timber is recovered as the work progresses, and the filling is drawn off to be reused elsewhere. The Mount Morgan ore deposit occurred at the surface as a round, isolated hill, or butte, and enjoyed unusual advantages for cheap mining, as far as breaking rock went, but being situated in a semi-desert made other expenses high, still the mine was worked at great profit in the early years of its history, and it is still a large producer, though the grade of its ores is lower than formerly. The underground workings now extend far below the level of the cut shown in the engraving above referred to.

For the lowest possible cost of extraction of its ores a mine must have a situation favorable to it. A mine located on a hill has an advantage over one that lies in a valley but little above the natural drainage level of the vicinity.

The accompanying sketches illustrate what may be termed an almost ideal condition with reference to economical working, and is only surpassed in this respect by a vein which may be worked to great depth by means of tunnels, making shafts unnecessary. Such a mine can be naturally drained and the ore throughout, to the drainage level, can be handled by gravity. In the case illustrated a less fortunate situation is conceived, and represents a medium condition, and one not uncommon in montainous mining regions. The object of the sketches is to show the va-

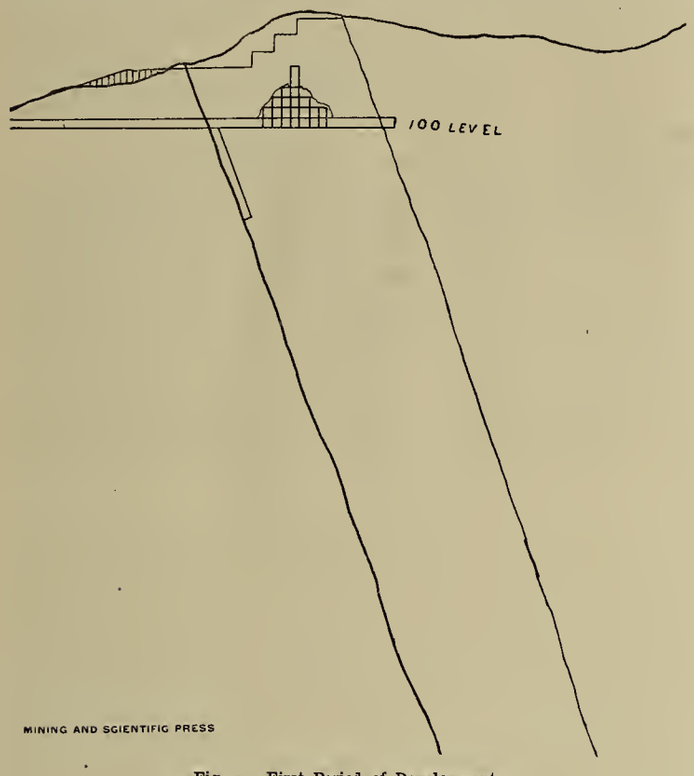

Fig. 1.—First Period of Development.

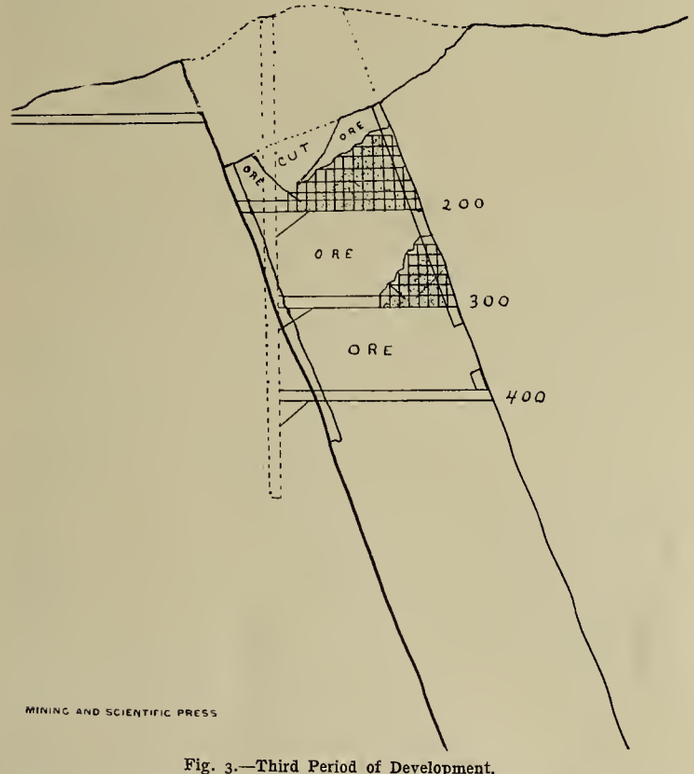

Fig. 3.—Third Period of Development.

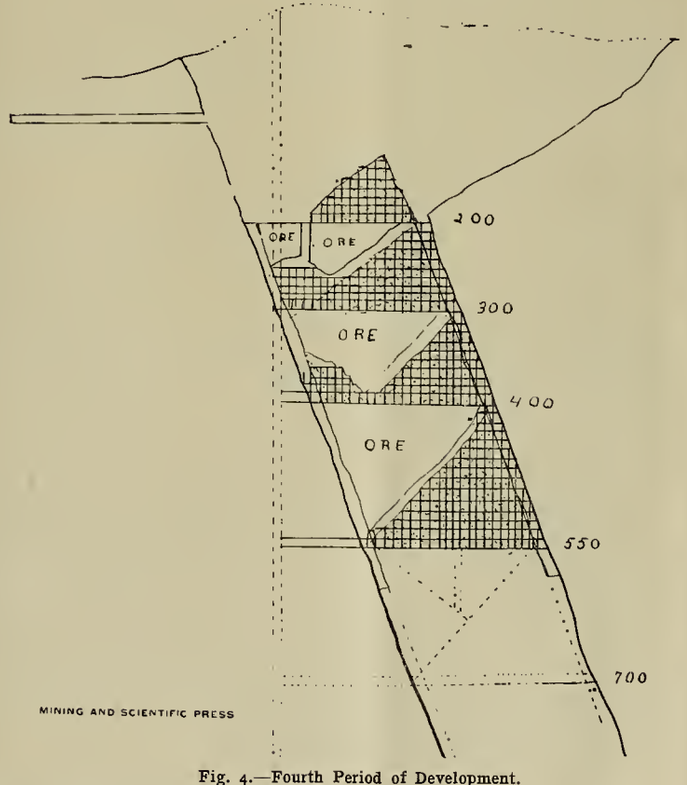

Fig. 4.—Fourth Period of Development.

rious methods of mining adopted from time to time, though it is not claimed that those of the early period, as illustrated, are worthy of emulation, but rather the reverse, under the circumstances which admit of a more economical method.

In the first period, the vein, which is represented as about 150 feet wide, was attacked by a series of terraces, similar to those at Mount Lyell, the ore being shoveled and thrown into chutes which delivered it at the lowest terrace to bins whence it was drawn off into cars and trammed to the incline, down which it was sent to the mill, supposed to be situated at the foot of the hill. During this period it was deemed wise to run a tunnel across the formatiou to the vein, and a stope was started in the heart of the ore body, the ground being supported by the square-set method of timbering. No filling was used during this early period, but a raise was driven upward in advance of the stoping operations. This raise eventually reached the floor of the terraced open cut, and mining by the "mill hole" system was commenced. Where it is possible to introduce this method of mining it should be done, as it is uudoubtedly the cheapest way of breaking and handling ore. In large veius a series of shots may be put in and fired simultaneously, and at times as much as 1000 tons at a blast can be broken down. The mill hole should be covered with a grizzly made of heavy logs to prevent jamming of the chute constructed in the chamber below, all large rocks being broken up before they are allowed to go to the bin. This can be done by hand on medium-sized rocks, but in the case of large masses powder must be used, either as surface shots, or by drilling holes a few inches deep in the mass aud charging these with powder. If the rock is hard it is better to use plenty of powder, and in "springing" the deep holes the ground should be shattered as much as possible before charging black powder or "low-nitro" iu order to cause the rock to break up as fine as possible.

The second period of development is shown in Fig. 2. A shaft has been started and sunk to a depth of about 400 feet. This shaft is presumed to be located along the strike of the vein, but uot necessarily directly withiu it. It is connected with the several levels by means of drifts, and, where necessary, by crosscuts also. A second level has been opened, and a winze, started on the foot wall of the vein at the adit level, has been continued below to the 200 level. A stope has also been started on this level, which is timbered by square sets, but no filling has, as yet, been introduced.

During the second period it will be noticed that in removing the ore by the mill-hole system a considerable block of hanging ground has been taken out, either from uecessity or intentionally. This was sent down through the mill hole and trammed out through the tunnel and dumped. Operating in this manner, it is found that the method is susceptible of improvement, and a third period in the mine's history has been reached. The great mass of overburden has become a source of expense, and of danger, as well, if the open cut method is to be followed. Fig. 3 shows the condition as it is found in the third period. The stope on the 200 level has been carried back to the hanging wall, and a raise made along the wall to the surface, aud the overburden is now beiug iutentionally broken, the debris being sent down the winze to fill the stope below. The winze on the foot wall has been continued downward, the main shaft sunk below the 400 level, and that level started by running a crosscut from the shaft to and across the vein to the hanging wall, where a raise has been begun to meet a winze being sunk below the 300 level. A raise has been put up in the back of the 200 stope, and a quantity of ore is still being broken in the opeu cut, which passes downward through the mill hole to be loaded into cars and trammed to the shaft. A stope has also been opened on the 300 level, into which filliug from the hanging wall surface is introduced, an apron controlling the direction of this rock on the 200 level. It will be observed that the stope ou the 300 level has been started adjacent to the hanging wall to take advantage of the opportunity to distribute the waste in the stope by gravity. This waste will run from the hanging wall mill hole, forming a conic section, lying on the floor of the stope aud extending upward along the hanging wall. It will have a uniform slope into the stope of about 35°, and can bc extended upward to the level above. It may then be necessary to shovel some of the waste. In this condition of the operation of the mine, we conceive that the fourth period of the development has been reached.

In Fig. 4 the conditions are found materially changed for the better. The main shaft has been deepened to about 800 feet; the 400 level is well opened up, and on that level, as well as the 300 level, separate stopes have been opened near the foot wall. From the 300 level a raise has beeu put through to the 200 level, and the filling originally in the stope on that level has been partially used in filling the stope immediately below it, and a good amount of timber, and wood for fuel, is being recovered from these old workings. This point has been previously referred to in connection with the opcration of the Mount Morgan mine. On the 400 level a stope has also been opened near the foot wall of the vein, and filliug from the surface can be sent into that stope diagonally and dowuwardly across from the 200 level to the 300 level. When this work is completed, a raise from the apex of the inverted wedge of ore remaining above the 400 level will make it possible to fill that excavation also from the 300 level.

In opening the 550 level it has been determined to increase the distance between levels, in order to reduce expeuse of preliminary work, and to make it possible to fill the stope on that level to the full extent possible by gravity. The waste from the hanging wall will now extend from the point where the 400 level joins the hanging wall to where the 550 level joins the foot wall. The block of ore lying along the foot wall above the 550 level may be removed and filled iu the same manner as was done on the 400 level.

The dotted lines below the 550 level show proposed development below that level. The winzes are continued along both walls, and the triangular space next the hanging wall indicates what portion may be filled from the hanging side. That adjacent to the foot wall shows what may be filled from the foot wall side, the waste being directed into that winze from 550 level, either coming directly from the surface, or from filliug already in place above the 550 level. A vertical raise is also showu in the center of the 700 stope to reach the fill above the 550 level.

Iu this way the development of the mine will progress. It is evident that the later methods are those calculated to reduce the cost of mining to the lowest figure. The details of mining have thus far been omitted, it beiug the intention to first merely outline the general plan of development.

(TO BE CONTINUED.)

Steel Head Frame at the Gwin Mine.

At the Gwin mine, near Valley Spring, in Calaveras county, Cal., a new steel head frame has been completed at a total cost of a little over $13,300. The Gwin mine is situated in a deep canyon, and the ground about the collar of the shaft has been filled to a depth of not less than 26 feet, and in some places it exceeds 30 feet. This rendered the cost higher than it would have been had no concrete foundations been necessary. The shaft is vertical and has reached a depth of nearly 2000 feet. A crosscut from the 1900 level has recently reached the vein, which was passed through by the shaft at about the 1200 level.

The frame proper sets on heavy concrete foundations, and is 100 feet in height from the sills to the center of the sheaves. It contains thirty tons of steel, and is of the "A" type. The general appearance of the frame and its position relative to the hoist is shown in the engraving on the front page. The shaft was sunk, and the mine has been operated, up to the time of the completion of the steel frame, by means of a hoist situated on the opposite side of the shaft. The original head frame was of timber.

This disposition of the two hoists made it possible to operate the mine uninterruptedly during the construction of the steel frame. In addition to the sinking of caisson-like piers, the site of the steel frame was underlaid by two water-wheel pits and a drain tunnel, neither of which were disturbed during the work, but which added to the expense of construction. Following is an itemized statement of the cost of this frame completed:

Labor on foundation, cement and two large iron cylinders for piers	$705 19
Contract for frame	4,000 00
Hauling from railroad	231 21
Extra hand rail	135 00
Incidentals	14 62
Two 10-foot sheaves and shafting	475 00
Total	$5,561 02

ORE BINS AND HOUSE.

Labor on foundations	$567 86
Cement	323 70
Lumber	1,523 80
Windows and frames	40 00
Corrugated iron sheathing	442 20
Labor on frame	1,914 65
Hardware, etc	100 41
New grizzly	254 68
New breaker	775 00
Old breaker	400 00
Shafting, etc., for same	218 00
Two 6-foot Pelton wheels	1,090 00
Hauling and freight	23 63
Total	$7,773 88
Cost frame	5,561 02
Total cost	$13,334 90

The rock skips have a capacity of four tons, and with skip aud cable weigh, when at the 1900-foot level, about 30,000 pounds. The water tank holds 1200 gallons. A round trip is made from the 1750 level with the rock skips in three minutes, including loading and dumping. This makes it possible with two skips running to hoist forty loads per hour, or 160 tons per hour. The hoisting reels are 10 feet in diameter, cylindrical in shape, and are operated by cut gears, 12 feet in diameter, the pinions being 36 inches in diameter.

Two high-lift ceutrifugal pumps, operated by three-phase induction motors, have been installed by the De Beers M. Co. of South Africa, says the Mechanical Engineer of London. One of the pumps contains four chambers and is designed to lift 1000 gallons of water per minute against a total head of 320 feet. The pump is driven through a flexible coupling by a three-phase induction motor, taking power from a fifty-cycle circuit at a pressnre of 220 volts, and giving 150 H. P. at 730 revolutions per minute. This motor is started by a water rheostat. The second high-lift pump has two chambers, and is arranged to lift 1000 gallous of water per miuute against a total head of 160 feet. It is driveu by a three-phase induction motor giving 75 H. P. at 730 revolutions per minute. In designing these motors a high efficieucy was sought, because, when installed iu the mine, ventilation would be poor and the work would be continuous.

Mining Addresses.

Written for the MINING AND SCIENTIFIC PRESS by CHARLES H. FITCH

During the past twenty years I have had much occasion to use mining addresses, and think that a few things I have learned regarding them may interest other users.

In the first place, I am absolutely convinced that the use of such addresses for sending out circulars can never be made to take the place of display advertising in miniug papers. When such a paper as the MINING AND SCIENTIFIC PRESS has been reliable and popular, a favorite with mining people, for I reckon not how many years, to turn from it to circularizing is like leaving a smooth, well-built turnpike and trying to drive your wagon over plowed ground. If we have a machine or tool of large use, the first thing to be done to maintain that use, and keep it from being displaced, is to keep the picture and merits of the thing before the people in such a paper. That is simply using the railroad and paying the fare. Circularizing, like walking, may seem cheaper, but it is not, being out of the question in economic comparison.

But we must use addresses in correspondeuce, as well as in circulars, following up the good introduction and perpetual reminder furnished by the mining paper. Also as we might judiciously walk a few blocks instead of taking a train, there are some things of minor demand not sufficient to pay for display advertising, in which a nice little business may be picked up by circularizing, especially where the circulars can be used as "riders" with other mail matter, so traveling practically postage free.

Mine addresses, as a rule, have a large degree of inconstancy. Where a list of merchants, such as might be used by wholesale dealers, changes 10%, a list of mines will in the same time show about 30% of changes. This does not at all argue against the stability of mining as a judicious investment by experienced people, but mines are started differently from stores; there is more of the speculative element, more experience is needed and less is used. Many mining enterprises "die a-borning," like unfortunate infants, their promoters "lie down" from lack of capital for larger investment, and even a good mine, well exploited, is often worked out, and its succcssful managers turn to new locations, leaving the old name and place a blank.

Hence, mining directories are always in disrepute. "We once tried," said a representative of an Eastern paper, "to publish a mining directory, but we found that it was bringing us into discredit and gave it up." Poole's directory, as good as any, was gotten out on the "try it every few years" plan. After an issue the publishers seemed to be too tired to try again for several years. A man who sent letters to every address claimed that 60% came back, but perhaps he did not send them promptly after the book was published.

Geo. W. Ramage of Chicago started a semi-aunual mine directory, with novel copyrighted features, weekly bulletins, etc. In less than a year he gave it up, claiming that he had sunk $18,000. Other directories have beeu published in Denver, New York and San Francisco, but the best of them serve only an ephemeral purpose, and the uusatisfactory results obtainable at best seem to discourage painstaking accuracy in their preparatiou. The MINING AND SCIENTIFIC PRESS published an excellent list of California mining properties, but closed the edition owing to changes. I think that only between 10% and 20% of California gold prospects are on a really active basis, such as would interest sellers of machinery and supplies. The rest are developing, or in litigation, or idle, waiting for capital.

Other inconveniences are changes of officers—personal address being always desirable—changes of name and corporation, and management of up to as many as a dozen concerns by one man. Such a man in receipt of circulars gets rather tired of the twelve-times-told tale, "A Twice-told Tale" being sufficiently vexatious, according to Hawthorne. If he is kind enough to writc the machinery man about it, the clerk of the latter probably goes on sending the duplicates. An instance of clerical stupidity occurred in the use of Poole's directory. The mine addresses were very clearly given in one place, and in another the character of mine—as gold, silver, copper, etc. A stenographer was found to be using these descriptive columns as postoffices. It was a man—a woman would not have been so stupid. There is a little postoffice called Gold in California. Near it are a few prospects. Not until the postmaster at Gold

reported the receipt of hundreds of letters for mines elsewhere was the blundering discovered.

Mining news tells us what properties are alive and likely to be in the market. It is invaluable, but often very fallible. A New York mining paper published a departmeut of news for machinery and supply men, in which mistakes were so numerous as to seem intentional. I wrote them, calling attention to fourteen errors in twelve lines of type, and advised them to quit. They did.

How shall we keep the best possible list?

It involves some labor. We must have the best available stable list, and must check it by news. The news is reported by counties, which have no postoffice address value, but we must keep it by counties for this reason, also giving postoffices. Mining camps are often mentioned, and I have for some States the postoffice of every mining camp.

Having a supposedly correct list for a year, say 1904, check mines mentioned in news as active with a 4. At the end of 1904 strike out all the names not so checked after use of return postals, in addition to press news. Then begin to check by 5 in 1905. Keep nothing over a year old.

I prefer book page lists by counties. You see the county at a glance. Cards require say forty handlings to see as much, and they stick together and get misplaced, and are a great nuisance. Reference to officers, reports, etc., may be made to other books or pages. Now, if you see a press item important to follow up, but without complete address, your mines book will be likely to help you out.

Have a column to indicate responses, inquiries and orders. The salesman should supervise this work, and the clerk attending to it should know when a "hit" is made. This will keep him encouraged and interested, without which his work will become perfunctory and unintelligent.

I would not ordinarily send out manifold letters. The deception may be cleverly done, but the nature of the letter "gives it away." I would not circularize by letters at all. A letter presumably calls for a reply, and annoys. I do not want a reply (except in case of return postals to keep up address list), unless I can do the party some good. For circulars I would send something of value, apart from what I have to sell. Such are vest pocket compilations of useful data, blotters, calendars, thermometers, etc.—something that will, if possible, be cherished, yet not cost too much.

A letter, if sent, should be a letter based on information of what requirements or conditions are in sight. When you ask for information always try to give some when you ask. Your customer will then feel like working with you, and you will get a good many points in one place which will be useful in another. Put yourself in his place, and think first of the "fish that he has to fry." In this spirit he will be likely to give your fish a chance, and will not be bored by your epistolary calls.

A Cripple Creek, Colo., Mine.

The accompanying illustration is that of the Vindicator mine, shaft No. 2, in Cripple Creek district,

No. 2 Shaft, Vindicator Mine, Cripple Creek, Colo.

and one of the important properties of that section. It was in the Vindicator shaft that a mysterious explosion of nitro powder occurred at the station on the sixth level a short time since, which wrecked the station and killed the superintendent and foreman, who were passing the station at the moment of the explosion. The damage has been repaired and the mine is again in active operation.

Testing Ores for Cyanide Treatment.

Written for the MINING AND SCIENTIFIC PRESS by R. STUART BROWNE.

There have always been two antithetical views regarding the value of metallurgical investigations made in the laboratory. Undoubtedly it is unwise to place too much dependence on results obtained from a miniature scale of work. But is it not likewise the extreme of foolhardiness to undertake the erection of an expensive reduction plant when an investigation might have demonstrated its unfitness beforehand? Witness the fruits of the opinions of these rash extremists in the abandoned mills dotting the hillsides of our mining camps.

To what degree can laboratory work be accepted as indicating the probable behavior of a process on a large scale? This is a difficult question to answer. The writer has had considerable experience in carrying to maturity plans elaborated from laboratory investigation, and gives as his own opinion that the results of careful laboratory work can be duplicated in a mill if sufficient attention be given to the reproduction, approximately, of the same conditions.

I do not wish it understood that I have such faith in the infallibility of laboratory work that I would advise the erection of a mill on the obtaining of a favorable extraction from a sample of two or three pounds. There may be cases where the preliminary investigation on a small scale will show so conclusively the fitness of the process for the ore that it is safe to proceed to build, but as a general rule, after selecting a form of treatment, a final test should be made on a scale commensurate with the importance of the work and the facilities available.

There are metallurgical processes where laboratory work would be impracticable—e. g., smelting. Still, it is not necessary to test an ore to determine its fitness for this. An analysis of the sample will furnish the requisite information. The adaptability of an ore to mechanical concentration is always a difficult matter to determine, unless the work is conducted on a working scale. Concentration is a delicate operation, calling for a nicety of adjustment of movements, water supply, feed, and a number of matters that play a small but important part in the work. Results obtained from any other source than the actual work of a standard size machine are of doubtful value. But, nevertheless, the laboratory can supply data from a chemical, physical and mineralogical examination so that the probable behavior of the ore can be foretold, and the indiscriminate testing by various machines avoided.

It is with the lixiviation processes that the real value of laboratory investigation makes itself apparent. Particularly is this true of the cyanide process and its vast number of modifications. In this article the writer will endeavor to give a general outline of the method of procedure in determining the adaptability of an ore to this class of treatment. The subject matter is not altogether new, but as it is more complete than what has appeared on the subject, and embraces a few new ideas—the result of his own experience—he presents it to his colaborers in this interesting field.

THE SAMPLE.—It might seem superfluous to dwell upon the importance of getting an accurate sample of the ore, but any one who has had much experience in a laboratory will understand how rarely such samples are brought in. In the case where a metallurgical process has failed to treat an ore successfully after an experimental investigation, the fault can usually be traced to the non-representative character of the sample worked with. A sample that represents nothing but itself is not only valueless, but apt to cause the useless expenditure of large sums of money. Let the sample be sufficiently large to represent the ore from every part of the mine, and let it be of the same general character as that which would be sent to the mill. Should the mine produce two or more distinct classes of ore, separate samples should be taken of each, for it may be necessary to subject them to different kinds of treatment. A frequent source of trouble is the failure to include the proper proportion of waste matter. In the process of mining, wall rock invariably creeps into the ore. The amount so included is variable, but a rough estimate can be made and the necessary amount added to the laboratory sample.

The sampling of tailings deposited in a reservoir is in most cases a simple matter, and susceptible to a high degree of accuracy. The most convenient way of taking the samples is by means of a borer similar to the ones employed in testing placer ground. These take out a core which forms an ideal sample, and also determines the depth of the deposit. They work best in ground which contains sufficient moisture to prevent the ground from running. Where the borer is not employed, pits must be dug, and the sample taken from a shallow groove running from the top to the bottom of the excavation. It is best to take these samples along the line of a geometrical figure, as it facilitates calculations of the tonnage, if measurements of depth are taken at these spots. The practice of taking grab samples from the surface of the tailing is to be severely condemned. It has been observed that in the arid regions what may be termed surface enrichment sometimes takes place with tailings that have come from lixiviation works. Such tailings always contain values that have not been removed by the water wash, and capillary attraction brings them to the surface. This phenomenon does not take place so readily with sandy material, but with slimes it always occurs to a more or less extent.

An important thing to consider in taking the samples is the relative amount of coarse and fine material. The slimes always lie at the point farthest from the intake of the reservoir, and from the difference in their physical and chemical condition sometimes require a treatment different from the sandy material. In estimating the tonnage, a convenient way of finding the weight of the tailings is by filling a small box with a weighed amount of the dry tailings, and then packing them down by the addition of water. By measuring the space occupied by a weighed amount of the wet material, it is easy to figure out the number of cubic feet required to make a ton.

PHYSICAL CHARACTERISTICS.—We will suppose that we have received a sample of ore to be tested for cyanide treatment. The first thing to do is to make an examination of its physical properties in order to determine their probable influence on the proposed method of treatment. Determine the specific gravity of the ore and its texture. See whether it be hard, soft, tough, friable, porous or close grained. From this a general opinion may be formed as to the mechanical treatment the ore will have to undergo, and its probable behavior under the conditions. A hard, massive quartz would indicate fine crushing, while a soft or friable one would mean coarse crushing in order to avoid sliming. Sometimes a clew may be found regarding the mode of distribution of the values in the ore—e. g., a system of fractures would suggest that the precious metals lay between the planes, in which case coarse crushing in a rock breaker might be sufficient to prepare the ore for the solutions.

The character of the wall rocks and the gouge, if one accompanies the vein, must be looked into. A gouge of clay or soft, decomposed matter, or wall rocks with a tendency to form slimes, is always bad and may exert a powerful influence on the work by retarding percolation.

In the case of tailings the physical examination would be confined to determining the proportion of slimes and sand. This is of importance only with slimy material, where percolation is dubious; but with sands where percolation is obviously practicable it is of little consequence and may be omitted. The method that I usually adopt in making this determination is to take 500 grams of the material, dried and accurately weighed, and remove the fines by agitation and decantation. The remaining portion is then dried, weighed and the slimes calculated by difference. The sample should be shaken in a large bottle, and sufficient time given for the heavier particles to settle, before pouring off the water carrying the suspended matter. After three or four washings it is safe to consider the remaining portion as sands.

The sizing test made by passing a weighed amount of the dry tailings through sieves of various sizes, and determining the percentages retained by each one, is of little practical value. The vital point is to determine the leachable and unleachable portions. This resolves itself into a question as to what constitutes slimes. I would define slimes as material so fine that when packed the percolation of a solution through it is stopped,

or else goes on so slowly that for all practical purposes it may be considered nil. The definition of the word must necessarily be elastic, and any attempt to limit it to material of any particular dimension must fail, for the size that constitutes the slimes of one man produces the leachable pulp of another.

These tests are of value simply for the analytical consideration of the leachability of the pulp, and in all doubtful cases must be determined from a trial run on a fairly large scale. As every one knows who has had very much experience with the process, the mechanical difficulties in cyaniding are of about as much frequence as the chemical ones, and this preliminary examination, apparently unimportant, may yield valuable information.

MINERALOGICAL EXAMINATION.—An attempt should be made to determine the various minerals in the ore, and the amount of the more important ones. Particular attention must be paid to seeing if compounds of copper, arsenic, antimony and tellurium are present. Frequently they will occur in such minute quantities that a chemical analysis of small amounts may fail to disclose their presence, and yet be in sufficient amount to eventually give trouble in the metallurgical operations. Particularly is this true of copper. The best thing to do is to crush down two or three pounds of the sample, pan it, and then examine the concentrates. If possible, a determination should be made of the forms in which the gold and silver occur. Free gold can always be shown by panning, and tellurides by the presence of tellurium in the concentrates. Should the sulphurets carry the values, the fact can be established by panning out some, removing the free gold by amalgamation, and then obtaining their values by assaying.

(TO BE CONTINUED.)

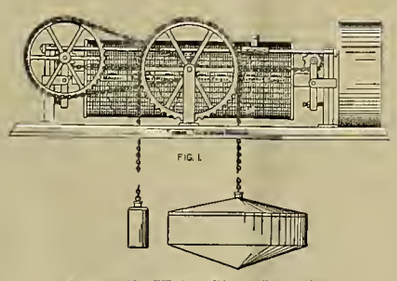
Automatic Water Stage Recorder.

Since the field work under the direction of the United States irrigation investigation began the use of water registers has grown in favor. For many years inventors have striven to design an automatic regulating gate to furnish a constant discharge under a varying head with unsatisfactory result, for the "ditch rider" is still compelled to read the depth of water flowing over a weir or through a flume as often as his other duties permit. The water register takes the place of the ditch rider, and its work is more accurate and is continuous. It also gives an impartial record.

If the user of the water and the party who furnishes the same are present when the register is installed and both are satisfied that the pen records the proper depth at that time, the week's record should be satisfactory to all concerned.

The water register used in this work can be kept locked and the records watched and the computations made by a disinterested party. The depth of water flowing over the weir or other measuring device can be checked whenever there is any doubt as to the accuracy of the record. The register sheets can be computed at the end of the irrigation season, and the volume of water corresponding to the recorded depths can be found in a few minutes. If the irrigation season covers a period of four months there are only sixteen or seventeen register sheets to be considered. It has been found to be more satisfactory to the company disposing of the water, as well as to the irrigator, to be informed of the volume of water furnished rather than to contract for the delivery of a definite number of cubic feet per second for an indefinite period, and for neither one to know whether or not the specified volume was being delivered.

J. S. J. Lallie of Denver, Colo., has invented an automatic water stage recorder, herewith illustrated,



Automatic Water Stage Recorder.

in which the rise and fall of the water in the reservoir, river, canal or flume raises and lowers a float and counterpoise. The float and counterpoise are connected by a substantial chain which passes over a cut sprocket wheel, motion being imparted by the float, and rises and falls with the changes of level in the river, reservoir or canal. A paper divided and ruled into rectangular spaces is securely fastened to the cylinder and the time divisions running parallel to the axis of the cylinder, and the depth divisions at right angles thereto. The pen or pencil making the record is moved along the cylinder by the positive action of the sprocket chain connected to the float, in which the movement from the float to the pencil point is positive at all times and under all conditions of water and weather. The fluctuations in discharge create a zigzag line and the mechanism is so constructed that the record can be extended to cover several revolutions of the cylinder if necessary, with no confusion of the record.

Gold Deposits of New Zealand.*

Written by ALEXANDER MCKAY.

Gold was discovered at Coromandel in 1852; at Collingwood, Nelson, in 1857; at Gabriel's Gully, Otago, in 1861; and on the west coast of the South Island in 1864. In all cases the gold was first obtained from alluvial or slope deposits.

In the Preservation Inlet and Wilson River Goldfield auriferous reefs have been discovered, the yield from which might be held to indicate these as a source of the alluvial gold of the district. This may be true as regards the reefs, but it is also certain that a considerable part of the alluvial gold has been derived from a source outside the area within which the reefs occur. The balance of gold from the two sources is therefore accidental.

On the Orepuki and Longwood Range Field no payable quartz lodes have been discovered, and the alluvial gold, it has been shown, had a source distant from where it is now found. In this case the alluvial gold does not indicate the existence of reefs in the neighborhood.

The goldfields on the west slopes of the Richardson mountains, though containing but one known payable reef, yet gives evidence that the alluvial gold has been locally derived, the gold being confined to the beds of mountain streams which expose only schist rocks, in which, though not abundant, quartz lodes occur at intervals. Areas of schist rock, strongly foliated with laminæ of quartz, appear in the middle and northern part of the range.

In the Shotover Valley Goldfield but few reefs have been found, and the yield of gold from these has been totally disproportionate to the amount of alluvial gold obtained from the district. Although at no point have the cements and quartz gravels at the base of the coal-bearing series been worked for gold, it is certain that they have yielded gold to the enrichment of the modern gravels in the tributary streams and to the Shotover itself. The great amount of alluvial gold obtained from this field does not indicate a corresponding abundance and richness of auriferous quartz lodes within the district.

In the Arrow River Goldfield the number and richness of the gold-bearing reefs as yet discovered are scarcely the equivalent of the alluvial gold found; but the great bulk of the gold obtained on the Arrow River was from a little above the junction of the river with the Kawarau, and it is certain that over this part the gravels worked have been enriched from a source not within, but west of the Arrow Valley. The gold in the upper valley above the Arrow Valley. The gold in the upper valley above the Arrow Falls probably had its source in the reefs of the district; and, having regard to this only, the amounts of alluvial and reef gold are proportionate.

In the Cardrona Goldfield, although gold-bearing reefs probably occur, none are being worked. The alluvial gold, as regards its original source, is for the most part foreign to the valley.

On the Mount Criffel and Luggate Creek Goldfield the alluvial and cement gold is also foreign to the district. Lodes of gold-bearing quartz are of probable occurrence in the Mount Pisa range, but they have yet to be discovered, and the gold of the district is not an indication of their existence.

In the Kawarau Gorge and Roaring Meg Goldfield no workable gold-bearing reefs have been found. The alluvial gold of the Kawarau and its banks has been derived from various sources, while that of the Meg Stream may also in part be due to an extension south of the Doughboy line of quartz grits on the Criffel field.

In the Nevis Goldfield part of the gold may have come from reefs in the Carrick range, on the east side of the valley, and part also from reefs in the upper valley; nevertheless, the greater amount of gold obtained has been derived from heavy terraces of sandstone gravels and the quartz grits of the coal period. Therefore part only of the gold has been supplied from reefs in the Carrick range, and the alluvial gold is not a measure of the abundance and richness of the auriferous reefs of the Carrick range.

On the Upper Clutha and Bendigo Goldfield but one gold-bearing reef has been discovered and worked. This, the Cromwell reef, has yielded considerable gold, but it is impossible that it can account for the gold present in other parts of the field. Much of the gold got in the vicinity of the Cromwell reef has evidently come from a considerable distance, as shown by the character of the wash in which is found rocks that are not known in situ nearer than the Mount Alta range.

On the Bannockburn and Fraser River Goldfield, part of the gold is referable to reefs in the Carrick range, but here also the amount of alluvial gold, taken as an indication of the richness of the reefs, would prove misleading.

In the Clutha Valley, from the Fraser river to Roxburgh, the known reefs within this part of the Clutha watershed are not likely to have supplied more than a tenth of the gold found.

At Switzers, and over the Waikaia Valley Goldfield, few or no reefs have been found, and the greater part of the alluvial gold has been derived from reefs and rocks outside the watershed of the Mataura.

In the goldfields of the Mauuherikia, Idaburu, and Poolburn Valleys no reefs are being worked for gold, and it is certainly remarkable that over an extensive district, easily prospected for reefs, and which for forty years has yielded large annual returns of alluvial gold, there should have been no important discovery of gold in reefs. One reef that has been prospected at the northern end of Rough Ridge, and near Ophir, is what was known as Green's reef, which turned out to be a belt of mica-schist country, more than ordinarily laminated with quartz that carried a little gold, but not enough to pay for working the deposit.

In the goldfields between the Taieri and Clutha rivers known reefs are few. Some reefs are being worked in the Upper Taieri Valley, and the denudation of these may account for the gold found in the valley above Pigburn, where the auriferous grits terminate on the flanks of the Rock-and-Pillar range.

On the Waipori Goldfield the O. P. Q. reef has been worked, and some reefs carrying gold are known to exist in the valley of Lammerlaw creek; but these cannot account for the considerable amount of alluvial gold obtained from this goldfield. The presence of extensive deposits of quartz grits of at least Miocene age yielding gold otherwise accounts for the larger part of the gold found on this field.

On the Tuapeka Goldfield some small reefs carrying gold have been found near the source of the Tuapeka River, and the Canada reef may also be here considered; but reefs on this field have not yielded a percentum of the alluvial gold which has been raised, and scarcely deserve mention in this connection.

On the Maniototo Goldfield no reefs carrying payable gold are known to exist. A reef was found in the Catburn, and to some extent this was prospected, but nothing of value appears to have been found.

On the Taieri Ridge, Macrae's, and Nenthorn Goldfields a number of reefs have been found, but the yield of gold from these at no time bore any proportion to the alluvial gold raised, such as might lead to the inference that the latter had been directly derived from reefs in the district.

On the Moeraki and Maerewhenu Goldfields reefs are almost unknown. A reef has been discovered on Balruddry Run, between the Kurow and upper valley of the Kakanui river, and another, in the Otekaike Valley, was prospected many years ago. A battery was erected, and some crushing done, but the quartz proved too poor in gold, and the working of the reef has been discontinued.

As far as the goldfields of Otago are concerned, the unavoidable conclusion is that of the £23,000,000 to £24,000,000, representing the value of the gold raised since 1861, but a small part of it is the product of reef mining. Even at the present the disproportion is as great as it has ever been. This is most remarkable; the more so as the country generally, and more particularly the mountainous parts, afford great facilities for the detection of reefs.

*Abstract Report of Government Geologist.

Canadian Bounties on Lead.

Following is the law granting bounties on lead in Canada:

That it is expedient to repeal Chapter 8 of the statutes of 1898 entitled, "An act to provide for the payment of bounties on lead refined in Canada," and to enact as follows:

The Governor-General-in-Council may authorize the payment of a bounty of 75 cents per 100 pounds on lead contained in lead-bearing ores mined in Canada, such bounty to be paid to the producer or vender of such ores, upon evidence that such ores have been smelted in Canada; provided, that the sum to be paid as such bounty shall not exceed $500,000 in any fiscal year; provided, also, that when it appears to the satisfaction of the minister charged with the administration of this act that the standard price of pig lead in Loudon, England, exceeds £12 10s ($60.83) per ton of 2240 pounds, such bounty shall be reduced proportionately by the amount of such excess.

Payment of the said bounty may be made from time to time to the extent of 60% of the full bounty authorized, subject to adjustment at the close of each fiscal year. If at the close of any year it shall appear that during the year the quantity of lead produced on which the bounty is authorized exceeds 33,333 tons of 2000 pounds, the rate of bounty shall be reduced to such sum as will bring the payments for the year within the limit mentioned in Section 1.

If at any time it shall appear to the satisfaction of the Governor-in-Council that the charges for transportation and treatment of lead ores in Canada are excessive, or that there is any discrimination which prevents the smelting of such ores in Canada on fair

and reasonable terms, the Governor-in-Council may authorize the payment of bounty at such reduced rate as may be deemed just on the lead contained in such ores mined in Canada and exported for treatment abroad.

The said bounties shall cease and determine on the 30th day of June, 1908.

The Governor-in-Council may make regulations for carrying out the intention of this act.

Number Scheme for Mines.

TO THE EDITOR:—I have read with interest the several articles on "A Number Scheme for Mines," and recognizing merit in the methods of both Mr. Aldersou aud "Mine Superintendent," and realiziug that uearly every mine worked has its individual conditions, differeut schemes may be adopted. Twenty-five years ago I adopted a scheme, so far as I know original, of dividing my workiugs into spaces designuated by letters. All levels, whether opened by tunnels or shaft stations, are numbered 1, 2, 3, etc., without regard to the distance between, unless the distauce equaled about double the usual space, in which case I skip a number. To illustrate: If I am opeuiug a mine with very wide veins and large shoots of ore, it may be uecessary to have stations 50 feet apart, in which case the first station 50 feet would be No. 1; secoud station, 100 feet, No. 2, and continuing iu same manner. If levels are 100 feet apart the stations are numbered in the same manner, No. 1, 100 feet, No. 2, 200 feet. The spaces between levels I designate by letters, thus, from surface to No. 1 level is A space, between No. 1 aud No. 2 levels, B space, continuiug in same order. My ore chutes are numbered according to distance from station, north or south, east or west. For instance, if in a continuous, well defined vein, the ore chutes are 20 feet apart, they will number on No. 1 level No. 1 A, No. 2 A, No. 3 A, etc. No. 5 A would be 100 feet from the statiou. My winze spaces are divided in

Building and Observatory to be Erected by the State of Washington.

hundreds; No. 4 winze is located 400 feet from the shaft or crosscut, if shaft is vertical and off the vein. The same plan is used for crosscut tunnels, distauce is measured on the veiu or ore body. If working in two directions from a shaft the north or south, east or west, designation is used. Chutes aud winzes from No. 2 level are designated No. 1 B, No. 2 B. The letter indicates the space being worked, and the uumber the distance from the station. If a portion of the vein is barren, that portion is measured and numbers passed over. In case of several veins being worked from one shaft or tunnel opening, I have made a practice of naming the veins, usually the same name as given by locatiou, except where more than one vein is found in a claim, then a special name is given, and so marked on the mine map. One case in mind, we have twelve defined veins withiu our working territory, and no difficulty is experienced iu locating our chutes or winzes. If I have the naming of veins I prefer and adopt short names. If working both ways from a shaft or station, a simple arrangement by my system is to give even numbers to one side, and odd in the other direction. Thus, No. 5 A chute would be located 60 feet south on No. 1 level, and No. 8 C would be 80 feet north on No. 3 level. In two properties where we are openiug the vein by loug crosscut tunnels, and the tunnels are 200 feet apart, I designate the first crosscut No. 2 level; second, No. 4 level; third, No. 6 level, dividing each space by one blind drift along the vein from a main winze; these levels are No. 1, No. 3, No. 5, and the spaces lettered as before explained, two spaces between each crosscut tunnel level. I recognize the difficulty of using one scheme for all mines, but I illustrate my method, trustiug other mine operators may find it convenient to use at times. It is quite inconvenient to chauge methods once adopted, unless in opening a new miue, and eveu iu that case a superintendent having worked for several years and become accustomed to a method, finds it difficult to adopt something new that has no effect on the economy of working his mine.

B. M. NEWCOMB.

DRILLINGS from holes which have been drilled with the vein should be distrusted as furnishing a key to results, for not infrequently rich streaks occur in a vein parallel with the walls, and should the drill hole chauce to follow one of these possibly a 5-foot hole might indicate ore having a value of $100 per ton or more, wheu the ore broken there might uot average $10. For the same reason chips taken along the side of a vein that has beeu stripped, or a chaunel made aloug it, caunot be considered as properly representing the mass of ore adjacent to it. Ore that is spotted is difficult to sample, and only large samples can be trusted to represent eveu approximately the value of the vein. Many veins carry the values in their seams or ribbous, which are essentially parallel with the walls. In other veins the values occur in bunches with low grade or valueless material between. This latter class is most difficult to sample, either for daily report or for examination as a whole. In such iustauces mill or smelter returns ou large quantities are the safest means of determiuiug the value of the miue or any particular part of it.

California State Building at the St. Louis World's Fair.

State Buildings at St. Louis.

Preparations are goiug on in every mining State to make a creditable exhibit at the coming exhibition at St. Louis, Mo. Most of the miuing States will have separate buildings, some of which have been illustrated hereiu. The California State building, illustrated in the accompanying engraving, is to be built after the Moorish architecture, which has been adopted so largely in Spaiu and iu Spauish speaking countries. This style of architecture is also typical of the missions established throughout the West aud Mexico more than 100 years ago. The Califoruia building will be a duplicate of the Mission Santa Barbara, as far as outward appearances go, though, of course, far less substautial than the original.

The Washington State building, also illustrated herewith, is of such unusual style of architecture as to attract attention. It will be octagonal iu shape, having eight huge timbers rising from the base, and all uuiting near the top, formiug a pyramidal structure. The building will be divided iuto five stories, and will have a height of about 100 feet. It is said that it will be the ouly State building at the Exposition which will afford a geueral view of the grouuds, owing to its altitude. Au elevator is to be provided in the center of the building, which will take visitors to the observatory tower.

Power at Niagara.

Considering the prospective transmission of electric power from the Cauadian side at Niagara Falls to Toronto, Ont., says the American Mauufacturer, it is interesting to note that up to the present day the longest transmissiou from the big power houses at Niagara Falls, N. Y., is to Olcott, a distance of 39 miles, whereas the contemplated trausmissiou to Torouto will be over a distance of about 90 miles. Other places in the United States have longer transmissiou liues, but the fact remains that at Niagara Falls there is the greatest development of power the world knows.

The first power delivered by the Niagara Falls Power Co. was September 25, 1895. It weut to the Pittsburg Reduction Co. for the manufacture of aluminum. To-day the Niagara Falls Power Co. has 105,000 H. P. at its commaud, and of this wonderful amouut of energy, 57,365 H. P. is sold in Niagara Falls to twenty-four customers. Across the river 1900 H. P. is exported to Canada and 36,969 H. P. is sold in Tonawauda. To sixty-three customers in Buffalo, 23,421 H. P. is delivered, the largest individual customers there being the Buffalo Railway Co., which takes 7000 H. P. The Buffalo Geueral Electric Co. comes next, and takes 6000 H. P. Altogether the Iuteruational Railway takes 12,000 H. P. for the

operation of its lines in Buffalo, Lockport, Niagara Falls and other places. To Lockport 1500 H. P. is sent and 1000 H. P. goes to Olcott to operate an electric road.

In Niagara Falls the second largest consumer is the Pittsburg Reduction Co., which takes 8000 H. P., while the largest consumer of Niagara power in any place is the Union Carbide Co., of Niagara Falls, which takes 15,000 H. P. The Castner Electrolytic Alkali Co. uses 7000 H. P., and the International Paper Co. gets 7000 hydraulic H. P. The Carborundum Co. uses 5000 H. P., the other consumers ranging from 2000 H. P. down to 15 H. P.

Up to the present time, the Niagara Falls Power Co. has made an expenditure representing $13,000,000 and it pays one-fifth of the taxes of the city of Niagara Falls.

Accuracy of Commercial Samples and Assays.*

Written by Ernest H. Simonds.

One of the most frequent questions asked by students of assaying is with regard to the accuracy practically attainable by and demanded of assayers under the conditions of everyday work. This same question is asked with an equal interest by ore buyers and ore shippers; by the buyers, because they work on a margin, which is only a small percentage of the value of the ore, so that an erroneously high assay may wipe out their profit or cause actual loss; and by the shipper, because the ore and bullion sales generally comprise the total income of a mine.

The following discussion of this subject is based upon the assays of several thousand ore samples, and mill and metallurgical products of great variety as to character, contents and origin. The results of the writer are compared with those of about half a dozen other chemists of the highest reputation. The operations include the method of fire assay of gold and silver, the fire or the molybdate method for determining lead, and the iodide or the battery method for copper.

The limit of allowable error cannot be stated to be invariably a certain percentage of the amount of the metal present; because, except where only approximate results are needed as in assays at the mine of daily samples of the workings, as high a degree of accuracy is needed as is practically attainable; and this accuracy varies greatly according to the material to be assayed. The cause of this variance of possible accuracy is to be found in the lack of homogeneity of the pulp, in the composition of the material assayed, and in the contents of the ore in valuable metal, all of which are variable. The agreement in assays of the various common vehicles of gold and silver, or materials in which these metals go to market, will therefore be discussed separately. These materials are gold and silver bullion, silver sulphide, copper matte, pyritic concentrates, and silver-lead ore and concentrates.

Gold and Silver Bullion.—The fire assay of silver can be relied upon to within about two one-thousandths (0.2%) of the content, although, with care, more accurate results can easily be obtained by cupelling simultaneously with the assay, a proof center of approximately the same composition as the bullion. It should be remembered, however, that proof silver (1000 fine) must be used and not ordinary test or quartation silver, which, although free from gold, is only 997 or 999 fine. When the bullion to be assayed is 875 to 925 fine, United States coin silver makes a good proof center, as it can be relied upon to be 900 fine within one or two ten-thousandths. If a possible error of two one-thousandths is too great, the wet assay should be used.

The fire assay of gold bullion is one of the most accurate of quantitative determinations, hence its use for controlling not only the valuation of all gold bars both crude and fine, but also the gold coin of all countries. Assays of deposits of unparted gold bullion are reported to one-half a thousandth (0.05%), and results from assays of chips taken from the opposite corners of a bar, or of two assayers checking one another, should not differ by more than this amount, in any case where there is little base metal present and the bar has been well melted. Generally chips from opposite corners, top and bottom, of $2000 to $6000 bars do agree within one four-thousandth (0.025%), and occasionally balance exactly. The surcharge, or difference between the weight of the parted gold and the weight of gold actually present, is found by means of a check of proof gold, and varies between zero and one one-thousandth. It is usually four to seven-tenths of a thousandth. For accurate work proof gold and bullion rolls must be used, and the assay weights should be checked to prove them consistent. If the bullion is less than 100 fine in gold, assays of it ought to check to one-tenth of a thousandth (0.01%). Bullion containing much base metal must be sampled by dips, not by chips. The following table gives actual results obtained in valuing typical bars. Bars 1 and 2 are mill gold, or retorted amalgam, from the battery and plates of a California stamp mill. Bars 3 and 4 are cyanide bars, obtained by melting the gold sludge formed by acid refining of the zinc box precipitate of a cyanide plant; hence the base metal zinc is present. In bars 5 and 6, most of the base metal is lead. Bar 7 is base silver bullion from Mexico. The seller used the fire assay, the buyer the humid assay for silver:

Bar.	Weight (oz.)	Sample.	Seller. Gold.	Seller. Silver.	Buyer. Gold.	Buyer. Silver.
1	225	Dips	722.25	268	722½	265
			722.30	267		
2	50	Chips	713.65	...	714	...
			713.88	...	...	...
3	600	Borings	603.25	333½	602½	330
4	600	Borings	603.00	333	...	...
			607.00	334½	...	...
			607.25	335½	607½	...
5		Dips	81.00	595	81	591
			81.02	595½	...	...
6		Dips	84.34	593½	84.2	591
			84.35	592½	...	...
7	780	Dips	0.04	314.86	trace	316
			0.04	314.76	...	...

Silver Sulphide.—This material is obtained as a chemical precipitate by adding sodium or calcium sulphide to the silver solution in the thiosulphate leaching process. It gives pulps which are perfectly homogeneous, provided that in drying, they have not been overheated so as to cause partial conversion of the silver sulphide into metallic silver. The pulp contains from 3000 to 20,000 ounces of silver per ton, (averaging about 10,000 ounces), and from 1 to 100 ounces of gold per ton. The material is generally bought and sold on the basis of the results of the fire assay, without the corrections for slag or cupellation loss such as are made with silver bullion.

However, an assayer's duplicate assays should agree closely, within thirty ounces to the ton or 0.1%, on account of the homogeneity of the pulp. The fire assay for silver is not only not scientifically accurate, but it is not sufficiently accurate even for business purposes, the slag loss on 10,000 ounces of the precipitate being about fifty ounces, and the cupellation loss three times as great. The error could be rendered so small that it might be neglected by assaying the slag and the cupels and adding the silver they contain to that in the first bead, but this very much increases the labor of assaying. It would appear, therefore, that the silver should be determined by the Volhard† sulphocyuate titration, the insoluble residue being scorified and cupelled to recover the small amount of silver always found in it. This method gives results which agree within a few ounces in 15,000 with that obtained by the corrected fire assays and is much easier and quicker. The following results show what is possible with this material by uncorrected fire assay:

Assayer.	Method.	Oz. Gold.	Oz. Silver.
A	Crucible	29.90	11,293
A	Scorifier	30.00	11,278 and 11,308
B	Scorifier		11,323

Copper Matte.—This material also is perfectly homogeneous, and it is, therefore, easy to sample and to obtain from it duplicate assays agreeing closely. The gold can be determined with precision by the fire assay, and the copper, by the electrolytic method or by the iodide titration. The determination of the silver is more difficult, on account of the large percentage of copper (40% to 60%) contained in the matte. Each assayer must use his own judgment as to the best cupellation heat for producing uniformity of results. The fire assay for both gold and silver is always used in the West. The combination of wet and dry methods is claimed to be more accurate; the wet method is better for the determination of silver, but the fire assay is certainly more accurate for gold. The following table gives the results on "shipping matte" from three different furnaces in widely separated localities:

No.	Seller. oz. au.	Seller. oz. ag.	Seller. % cu.	Buyer. oz. au.	Buyer. oz. ag.	Buyer. % cu.	Umpire. oz. au.	Umpire. oz. ag.	Umpire. % cu.
1	9.85	64.20	34.23	9.81	...	34.00	....	65.29	....
2	16.47	91.20	50.15	16.47	91.70	49.90	....	....	....
3	11.97	73.74	28.67	11.83	74.50	28.70	12.00	72.80	....
4	13.39	69.20	35.65	13.33	69.80	36.90	13.33	....	35.80
5	30.03	285.95	49.25	....	....	49.30	30.04	286.90	50.24
6	1.28	41.26	52.20	1.24	41.35	52.30	....	....	....
7	1.45	35.15	55.70	1.47	35.30	....	....	....	55.77
8	1.37	34.51	48.74	1.32	33.16	....	....	....	48.73

In 1, 2, 3, 4 the buyer determined the gold and silver by scorification and the copper by electrolysis; the seller used the crucible assay for the gold and silver, and the iodide method for the copper. In 5 both buyer and seller used the crucible assay for the gold and silver and the iodide for the copper. In 6, 7 and 8 the seller used the scorification method with re-scorification of the buttons for the gold and silver, and the buyer used the crucible method; both used the iodide method for the copper.

In 1, 2, 3 and 4 the contract between the buyer and seller provided that: "Three samples are to be drawn, one for our joint assayer, one for the refiners and one to be reserved for an umpire in case the assays should vary from ½% for the copper, one ounce for the silver and 1-20 ounce for the gold; if the difference does not exceed the above splitting limits, the mean of the two assays to be taken for settlement, but if an umpire's assay should be made, the mean of the two nearest assays out of the three to be taken, and the party further away from the umpire's assay shall pay the umpire's charges for assaying." This seems a fair contract, as payment is always made on the average of two assays—the umpire's and the one nearest his—not on the umpire's assays alone. This particular matte was of higher grade than had been anticipated when the contract was drawn up, and hence there was some difficulty in coming within the prescribed limits of variation.

Grand Encampment District, Wyoming.

The mines of the Verde Mining & Milling Co., generally known as the Ferris-Haggerty, are 19 miles southwesterly from the town of Encampment, a place of about 1000 inhabitants, in Wyoming. Here are located the smelter of the Encampment Smelting Co., which treats the ores of the Ferris-Haggerty mine; the office of the Encampment Tramway Co., operating an aerial tram 16¼ miles in length; the Encampment Pipe Line & Ditch Co., owning a 48-inch stave-pipe line, used in developing power and supplying the smelter and town with water; electric lighting plant and other industrial and corporate companies, all owned by the North American Copper Co. Encampment is situated at an altitude of 7000 feet, and the mines at about 9000 to 10,000 feet above sea level, near the village of Battle, which is on the Continental divide, at an altitude of 10,000 feet, and is 7 miles from the mines.

The district was discovered in the winter of 1896-97. The principal mines discovered were the Doane-Rambler, Hercules, Portland, New Rambler and Ferris-Haggerty.

The Doane-Rambler and New Rambler have produced and shipped considerable high grade copper ore, principally chalcopyrite, a feature of the New Rambler being covellite carrying platinum.

The Ferris-Haggerty is the large producer of the district. This property is opened to a depth of 700 feet, with shafts, tunnels, drifts, crosscuts, raises and winzes, showing large ore reserves, blocked out; $700,000 had been produced (at a cost of $600,000) when the present owners, the North American Copper Co. (the principal parties in interest being the Carey Bros. of the Mine & Smelter Supply Co. of Denver, and Chas. Collins of Penusylvania, and his associates) purchased it for $1,000,000, and proceeded with the erection of the tramway, water power, smelter, etc., at a total additional cost of about $1,000,000. During September, 1903, the smelter made a test run of twenty days on 8% ore, concentrating about four into one, and shipping eleven carloads of refined copper averaging about 99¼%.

General Geology.—The geology of the Encampment region, says A. C. Spencer of the United States Geological Survey, when studied in detail, is found to be intricate, but the more general features can be readily outlined. Among the most prominent features of the region are bands of white quartzite. The bands or reefs of quartzite, which cross the country in a nearly east-west direction, are separated from one another sometimes by bands of conglomerate, slate, and limestone, and in other cases by dikes of dark diorite. All these formations have a general dip toward the south, and frequently stand at steep angles. Taken together, they occupy a narrow wedge-shaped area, extending for 20 miles westward from its point or apex below the mouth of Purgatory gulch on the Encampment river, a few miles south of Encampment. The widest part of the quartzite area is upon the west, where it becomes covered by surface formations in the drainage of Big Sandstone creek and of Savery river. With the exception of the diorite, all the rocks mentioned are of sedimentary origin, thrown into east-west folds by compressive forces acting in a north-south direction. The diorites were intruded into the sedimentary series after the greater part of the folding and compression had taken place. They occur in dikes from a few feet up to half a mile in width, frequently extending along the strike for several miles. They are of almost universal occurrence throughout the quartzite belt, and are also found cutting the granites, gneisses and schists which occur both to the north and to the south of the quartzite. The schists are mostly hornblende schists, which may be seen in typical development upon the north slopes of the continental divide in the heads of Jack creek and North Spring creek, and also in the region of Huston Park. The other rocks of the mineral belt may be classed under the general names of granite and granite-gneiss, and all of these appear to have been formed since the hornblende schists, though they are probably older than quartzites and associated formations. The formations represented in the Sierra Madre are of pre-Cambrian age and belong to the most ancient series known within the Rocky Mountain province. The topography of the region is more than ordinarily smooth for a mountainous country reaching elevations above 10,000 feet, a fact which allows the building of wagon roads to almost any desired locality at comparatively slight expense.

Economic Geology.—The ore deposits of the Encampment region have not, as a rule, been developed to a sufficient depth to afford opportunity for an exhaustive study. Hence, while the few mines in the

district which have been opened to a cousiderable depth have been carefully studied, the information obtained with regard to the occurrence of economic deposits as a whole is largely based upon general geological relations ascertained from surface examinations.

ORES.—Copper is the predominant metal of value in the ores of the district, though there are a few deposits carrying values in silver, and gold occurs alone in quartz veins, or in variable but always small amounts accompanying the copper ores. The ores of copper comprise the sulphides, chalcopyrite, chalcocite, bornite, and covellite and their usual alteration products, malachite, azurite, chrysocolla, and the oxides. The silver-bearing ores are argentiferous galena, occurring with sphalerite and pyrite in fissures with a gangue of quartz, together with calcite, or the carbonate of iron, siderite.

THE COPPER DEPOSITS.—Considered in a geueral way, the deposits of copper in the region fall into two classes. The first class includes all where the mineral is chalcopyrite unaccompanied by oxides, carbonates of copper, or rich sulphides, except very superficially where the former minerals have been oxidized by surface weathering. Deposits of this sort, which occur invariably inclosed in undecomposed rock, are regarded as original ores. Their distribution is almost universal, and they are found in all sorts of rocks, frequeutly without any recognizable vein material, but sometimes accompanying masses of quartz with a small amount of feldspar, calcite, or siderite (carbonate of iron). In those cases where little vein matter is present the ore occurs, as a rule, in pockets or lenticular masses following the schistose or slate structure of the country rock, and more or less mixed with the inclosing material. No instances were observed where bodies of this character gave promises of sufficient size or permanence to warrant the expectation that they would lead to important masses of ore. As an exception to deposits of the above type where there is uo well-defined lead traceable for any considerable distance upon the surface, there are others, still without associated quartz, occurriug iu strong leads traceable for long distances upou the surface. A typical example of this variety of deposit is the Verde property. The Verde is a zone along which iutense metamorphism has taken place, involving hornblende schists, a band of limestone, and some thin strata of quartzite. The zone seems to follow the limestone which appears to lie parallel to the geueral schistosity of the regiou. There is every reason to anticipate that metamorphic zones of this kind will persist in depth, though the extent to which copper has been deposited in them must be proved by exploration. In a third type of original ores the copper pyrites occur in a matrix of quartz accompanied by calcite and siderite or by feldspar. The sulphide here occurs in bunches throughout the mass of the gangue, and the value of such veins is dependent upon their persistence. Some veins of this nature are lenticular bodies lying with their longest surface dimeusions parallel with the structure of the iuclosing rock. Certain of such masses of quartz reach a width of 50 feet or more, showing in outcrop a length of from twice to several times this figure, but these seldom show any considerable amount of copper, though they are reported to carry a small amouut of gold. Iu other cases the quartz occurs in a disconnected series of thiuner lenses, extending along the same general trend in the schistose rocks. Sometimes these interrupted veins carry chalcopyrite in promising amounts. If they are irregular and interrupted upon the surface, they are likely to be discontinuous in depth, but where strong and persistent iu outcrop they may be expected to continue in depth. This type includes such deposits as the Continental in Cow creek, the Cascade, aud the Kurtz-Chatterton. In the ores of the two properties last named there has been some secondary deposition of ore, but the sulphides are regarded as mainly primary. The second class of copper deposits iucludes all those where the principal copper minerals are rich sulphides, such as chalcocite or copper glance, covellite, and bornite, with or without high-grade copper pyrites. In the surface portion of such deposits large amounts of oxide and carbonate ore are found, and they are commonly capped at the outcrop with strong gossan. Also the inclosing country rock is often to a greater or less extent decomposed. Ores of this character are regarded as due to secoudary concentration or enrichmeut of ore bodies originally of low grade, through processes similar to those which have produced bonanza deposits in many other copper camps. The secoudary deposits of the Encampment district have beeu thus far the only ones supporting productive mines. The ores of the Charter Oak, Doane-Rambler, and Ferris-Haggerty mines are of this nature. At the Charter Oak, where the country rock is granite aud diorite, the deposit appears to have been extremely irregular, but in the other mines meutioned the deposits show considerable regularity iu their occurreuce. The ore bodies, inclosed in quartzite of sedimentary origin, occur in zones of shattered rock which follow the bedding of the quartzite. Courses of easy circulation for underground water have been afforded by local shatteriug of the rock, which doubtless determined the position of original deposition, aud later allowed of concentration to the form in which the ores are now found. In both the Doane-Rambler and the Ferris-Haggerty the secondary ores have been opened to a depth of more than 300 feet, though in neither instance has the lowest level of the workiugs penetrated more than a short distance below the beds of the gulches adjacent. From the present study of the region it appears that the future of the district must depend largely upon the discovery of additional deposits of the secondary class or type. That such deposits exist it seems fair to anticipate, but the best method for their discovery must be based upon a recognition of their character as distinct from the primary ores. Secondary ores will not be found where the inclosing rocks are tight and impervious to the circulation of atmospheric waters. They require loose formations due to brecciation or crushing of the country rock, as in the cases mentioued, and in some cases it is to be expected that the country rock will be greatly decomposed. Several locations were noted by the writer where gossan was present in encouraging amount, but where no adequate work had been done to prove the condition of the inclosing country rock or the significance of the gossan. Other properties show the presence of rich sulphides in crushed and decomposed diorite, and it is believed that these are worthy of careful investigation.

The hanging wall of the Verde is an altered granular schist and the foot wall (surface indications showing 25 to 30 feet in width) a high-grade lime carrying 50.02% oxide. The surface shows no values in miueral, but the vein can be traced at intervals throughout the entire length of the property (6000 feet) and 3000 feet farther east the surface showing the lime foot wall, with a capping of gossan on the south side.

The Chemistry of Ore Deposition.*

Written by JOHN A. CHURCH, New York City.

Prof. Jenney has performed a notable service in presenting a summary of the steadily increasing body of observation on the presence of carbon in rocks of all kinds and its probable influence upon ore deposition, and in formulating a mode of comparing directly the relative resistance of minerals to oxidation, as well as their reducing power, aud the protective action which minerals having higher reducing powers exert in preventing the oxidation of associated minerals which possess relatively lower affinities for oxygeu.

I have had an opportunity of observiug a vein which falls within the scope of his iuteresting discussion. The vein at Ku Shau Tzu, Mongolia, lies directly across a contact of limestone and overlying bituminous shales. Probably it occupies a compressiou fissure. The shale has been reduced to such a condition of non-coherence that much of it can be crushed in the haud, producing a handful of angular fragments resembling beech nuts in shape and size.

In the limestone the metals are principally in argentiferous galena with some pyrite and blende, but the latter two are very subordinate iu quantity to the galena. In short. it is a lead vein in limestone, with siliceous limestone gangue. It is one of those veins in which the orc is uot continuous, but consists of a band in the country rock in which seams of lead sulphide begin at one wall aud cross in a bent form, increasing in thickness, to the other wall, where they thin out and eud. This may indicate torsioual stress, but the shape of the lenses points to some other action. They often run nearly parallel to the hanging wall for a considerable distance and cross the vein on a moderate angle, but turn sharply on approaching the foot wall. The intermediate rock contains nodules, bunches and specks of ore, and the lenses vary exceedingly in size, shape and positiou in the vein.

In the bituminous shale the deposition of ore is not at all like that in the limestone. The minerals in the shale are tetrahedrite and native silver, the latter occurring in fine scales aud sheets of pure metal weighing from 50 to possibly 100 ouuces. I caunot speak of these larger sheets from much acquaintauce, for all but one of them were stolen by the miners, but the metallic silver in scales and sheets was an important part of the ore.

It is necessary to exclude the notion of secoudary deposition at Ku Shau Tzu, because the influence of the shale with its superabundant store of powerful reducing agent should have gathered to itself every metal takeu into solution by descendiug surface waters. Whether that was the case immediately at the surface I do uot know, as the mine was an old one when I first saw it. The absence of galena, blende and pyrite from the shale at depths of 300 and 400 feet indicates that secondary deposition, if present at any time, did not reach so far, and this was to be expected from the reducing power of the shale at the surface.

I cousidered that the conditions indicated deposition from a solution rising through the limestone first and afterward through the shale which once covered the lime rock, though now it is tilted and partially eroded. The limestone precipitated what it could, and the abundant store of carbon in the shale perhaps took the last traces of metal. But this explanation is not without its difficulties when applied to the limestone, however confident we may be of the reducing powers of shale.

There must have been some other selective agency than mere position or the chemical energy of carbon at work to produce these effects. The same considerations lead us to doubt that there was an interchange of elements between differeut parts of the ascending column of mineral solution, by which the complete precipitation of any mineral in one rock—the shale, for instance—would so dilute the mother liquor there that this mineral would pass by diffusiou from the solution going through the limestone to that in the shale. Such action is familiar in chemical work. When a drop of reagent causes partial precipitation the remainder of the dissolved substance is diffused immediately through the whole body of liquid. This could not have taken place at Ku Shau Tzu without producing more abundant deposition in one of the rocks than in the other, according to its precipitatiug energy, and the phenomenon there is uot quantitative, but selective, conceutration. The quantity of mineral was greatest in the limestoue.

There is evidence that the solution from which an ore of geueral average composition is deposited may produce ore bodies that vary in their differeut parts in a manner importaut to the miner if not to nature.

In the case of the Crown Point-Belcher bonanza, on the Comstock, one half the ore body contained more gold in proportion to silver than the other half, and the difference was not fortuitous, but persisted through the whole extent of the bonanza. The couutry rock was eruptive, the mass of the deposit was silica, the total length was only 500 feet, and it is difficult to see how there could have beeu selective depositiou from a uniform solution. Granting that the differeuce began at the poiut where the solution was formed, this difference in the two halves of the current must have been preserved throughout its wanderings—a proof that there were no exchanges between the two halves.

Of course, if lateral secretion iu its first and most restricted sense were true, and the ore were derived from the immediate walls of the vein, au explanation might be fouud. This extremely limited conception is, I believe, entirely abandoned, and the persistent differeuce of the Crown Point-Belcher solution along adjacent vertical and, perhaps, horizoutal lines of travel, possibly to great distances, is an unexplaiued phenomenon. Other cases are kuown in which the facts indicate that there was no exchange of elemeuts between the parts of the commou solution from which the respective ends of the ore body were formed.

It is not probable that the north and south ends of the Crown Point-Belcher ore body differ in date, for the mass was decidedly lenticular, very thick in the middle and thinning out in all directions. The natural conclusion is that the action, being a replacement of country rock, began in the central portion of the mass, and the greater thickness there is the effect of longer action. This is equivalent to sayiug that the actiou was continuous over the whole of the steadily increasing vein area, and that ore was forming in the center while it was forming at both ends.

A natural explanation of the Crown Point-Belcher case is that the thiu-leaved porphyry of the Comstock offered a meaus of ready flow, which operated as a chaunel, to which waters from widely different sources of origin were directed; but this only emphasizes the fact that the two currents maintained their individuality through long wanderiugs, and even when joiued in a channel of limited section. It also implies that gold and silver can be picked up anywhere in the middle of the earth, a conclusion which cannot be admitted, for it is probable that the solution of metals is as selective and phenomenal as is their depositiou.

Prof. Jenney's description of the ore deposition in the Tintic limestones may be accepted as accurate for the galena of the Emma mine, in Little Cottonwood canyon, Utah. I remember a large mass of galena there, almost pure in the center, and surrounded by a thick mass consistiug of decomposed limestoue fragments in galena, graduating to euclosures of galena in limestoue as the distauce from the ceuter increased, aud ending with scattered, small impregnatious of galena in the nearly unaltered limestoue walls. The angular shape of the iuclusions mentioned by Prof. Jenney was noteworthy here also.

Oue of the problems at Tombstone, Ariz., which the new owners are attacking with such faith is the future of the Coutention vein, where it passes through the Lucky Cuss limestone. which is strongly fetid for 100 or 200 feet in thickuess. It will be years before it is reached, but it presents the elements for active chemical exchanges. When I was superintendent in Tombstone two of my men, who were mining manganese iu the higher strata of this limestone, nearly lost their lives by an effusion of CO_2 into a shallow, open pit where they were working. The gas accumulated during the night and surprised them in the morning. These facts may indicate the influeuce of carbon in that mining district.

At the New Almadeu quicksilver mine there is an euormous discharge of carbon dioxide, which bubbles and hisses through the water in the bottom, and twice, at least, has so filled the large chambers of the old mine as to drive the whole mining force from its work.

*Trans. Am. Inst. Min. Engs. Discussion of paper by W. P. Jenney.

Smelter Practice at Black Diamond, Arizona.

TO THE EDITOR:—The Black Diamond Copper Mining Co. has now been operating its 200-ton copper furnace since Sept. 1, 1903, and as I consider that we have been doing some exceptional work for copper smelting, it will perhaps be of interest to the mining world to learn of the results that have been obtained during this period.

The furnace is of the rectangular water jacket type, 48x120 inches, with eight tuyeres to the side. In blowing in the furnace, a fire was started in the bottom of it with shavings and dry wood. To this was gradually added coke, as it caught fire, until the coke charge was a foot above the tuyeres, when a light blast was turned on the coke and kept there until the bed of coke was thoroughly afire. Then the charging of the furnace was begun, 2500 pounds of coke being used before any ore was added. From then on the regular charges of 2000 pounds of ore and 200 pounds of Colorado coke were fed to the furnace, until six tons of ore had been put in, when a heavier blast was turned on and gradually increased until twenty tons of ore had been charged, when the regular blast was employed. Slag began to flow within thirty-five minutes after increasing the blast the first time.

The slag and matte from the furnace flow into a large forehearth, and from this to a smaller one, and from there to the slag pot, holding three tons, and which is drawn over a heavy steel rail track to the slag dump and emptied, another pot being substituted after the removal of the first.

All the matte separates from the slag in the large forehearth and is tapped from there once every hour into pots holding 400 pounds. To avoid the danger of any matte running into the smaller settler and from there into the slag pot, this settler is tapped once every twenty-four hours; but very little matte is obtained here, showing that it virtually all separates in the first forehearth.

The ores from the different stopes in the mine, either singly or as a whole, are self-fluxing and very easy to smelt with a 10% coke charge, the slag being liquid and free running.

An analysis of the average ore being smelted is as follows:

SiO_2	30.70%	Zn	3.65%
Fe_2O_3	42.10%	S	6.10%
Al_2O_3	7.50%	Cu	4.10%
CaO	2.15%	Ag	10.10 ozs.
MgO	0.68%	Au	0.03 oz.
MnO_2	1.61%		

The matte produced from the above ore assayed Cu 65.43%, Ag 156.80 ozs., Au 0.50 oz., and the slag contained 0.31% Cu—this being a coucentration of 17½ to 1 for the Cu, 16 to 1 for the Ag and 17 to 1 for the Au.

Where the copper values in the ore have been low and with high values in the Ag and Au, we have made a concentration of 32 to 1 several times and produced an average matte of 75% Cu, the slag from this high-grade matte only containing 0.35% Cu, the Cu in the slags being determined by the colorimetric method, probably the most delicate and accurate manner for getting the percentage of Cu in slags.

Several different times we have produced matte containing 78% Cu, which is within 1.8% of the highest percentage of copper matte can contain (79.8%).

The great advantage to the company producing such high-grade matte is in the saving of freight, as it is all shipped to the Eastern refineries. The principal difficulty in making such high-grade matte is its tendency to raise the bottom, so that there is not sufficient depth to the crucible of the furnace, and also its liability of freezing up the forehearth and the difficulty of tapping it, as this matte chills so quickly. These are, however, much lesser evils than the other extreme—the low-grade matte of 35% to 45% Cu, with the great heat it contains and the danger of it eating through the bottom of the furnace and also through the sides and bottom of the forehearth, necessitating a coustant watch to prevent a "runaway" of the forehearth. Of the two mattes here, the furnace man prefers tappiug the higher grade.

Any grade of matte from 40% to 70% can be made here by feeding the furnace according to the percentage of copper wished.

Keeping the charge in the furnace high up towards the feed floor aud cold on top makes a low-grade matte, as it permits of very little roasting of the sulphide ores in going down the furnace, and the ore comes in contact with but little heat until the melting zone is encouutered, wheu the sudden melting throws almost all the percentage of sulphur into the matte, making it carry a high percentage of iron and sulphur and a correspondiugly small percentage of copper. Now, by running the charge low in the furnace, and hot all the way through, and yet not makiug the bottom of the furnace cold by drawing too much heat to the top, the sulphides have sufficient time before reaching the melting heat in the furnace to roast most of the sulphur out and only leave a small percentage to form the matte iu conjunction with the copper and iron.

In this manner we are now making all the matte average 65% Cu and keeping the furnace in fine condition.

Eight-hour shifts are worked in the smelter, and two feeders, a tapper, tapper's helper and slag man are employed to the shift on the furnace. Three charge wheelers work twelve-hour shifts, two wheeling ore and the third coke.

From six to eight charges per hour are fed to the furnace, and nothing in the way of fluxing material is added to the charge, except the foul slag, which is used as it accumulates from the matte yard.

The mine is opened up to a depth of 700 feet on the incline of the ore deposits, and several of the stopes are over 25 feet in width. Some of the ore broken assays as high as 35% Cu and 400 ounces Ag.

The mine has no difficulty in keeping the smelter operating. The iron in the ores is found almost entirely as the black oxide (magnetite), the balance being divided between the red oxide (hematite) and the iron combined with the copper sulphides.

The copper is fouud chiefly as the yellow sulphide (chalcopyrite). The balance is principally peacock copper, or bornite, and the surface carbonate ores. Native copper and the oxides melaconite and cuprite, with covellite, also occur in the mine. The alumina occurs as silicate, the lime as calcite and the zinc as blende (sphalerite); it occurs, however, in such small quantities as not to interfere with smelting operations.

To General Manager N. O. Bagge credit is due for managing aud finaucing this property. S. C. Lake is superintendent of the mine and smelter.

The western extension of the Black Diamond property is owned by the Dragoon Copper Mining Co., an incorporated company. This company is developing its property by a shaft, which is now down 400 feet, and by drifts from the same, and several large bodies of high-grade copper ore have been developed. The eastern extension in the same mineral zone and similar surface conditions is owned by L. R. Bailey and associates of this camp.

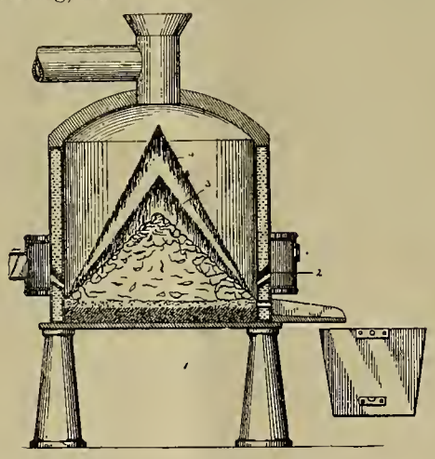
C. W. MITCHELL,
Metallurgist and Foreman in Smelter of Black Diamond Copper Co.

Mining and Metallurgical Patents.

PATENTS ISSUED DECEMBER 15, 1903.

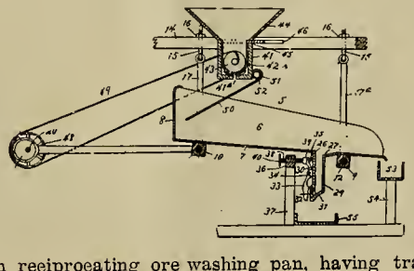
Specially Reported and Illustrated for the MINING AND SCIENTIFIC PRESS.

SMELTING ORES.—No. 746,970; J. W. MACDONALD, Pittsburg, Pa.



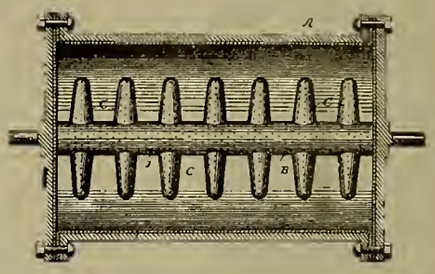
Process smelting sulphide ores by placing initial charge of raw sulphide ore on hearth, inclined sides comprising upper surface of charge being exposed, heating charge to temperature sufficient to enable portion of sulphur therein to combine with oxygen, forcing air upon exposed inclined sides of surface of charge, thereby effecting combustion of portion of sulphur aud enveloping eharge in mantle of flame and fusing outer portions of charge, aud feeding successive portions of raw ore upon surface to maintain charge constantly in form having iuclined sides to receive air upon its surface, and drawing off molten product, as required.

APPARATUS FOR SEPARATING AND CLEANING ORES.—No. 747,214; F. E. Parker, Kansas City, Mo.



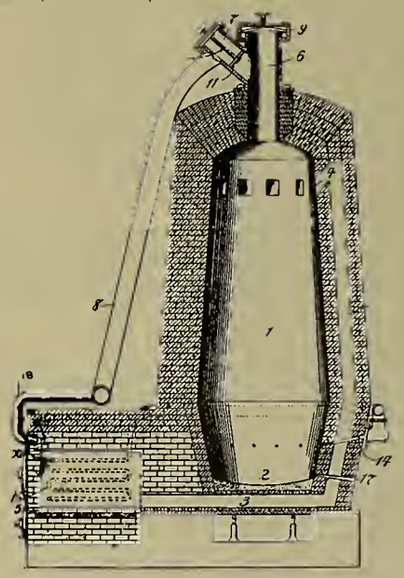
In reciprocating ore washing pan, having transverse opening in bottom thereof, pocket for ore connected with lower surface of pan beneath, opening having sides and ends and bottom inclined at angle to one side and discharge opening near inclined bottom, valve operating pivoted lever on one of sides having discharge opening, upper end of which lever is bent forwardly at angle to side of pocket, spring between bent end of lever and side of pocket, and stationary lever contacting device extending in direction of upper end of lever.

CHLORINATION BARREL.—No. 746,867; De Witt C. Mosher, Colorado City, Colo.



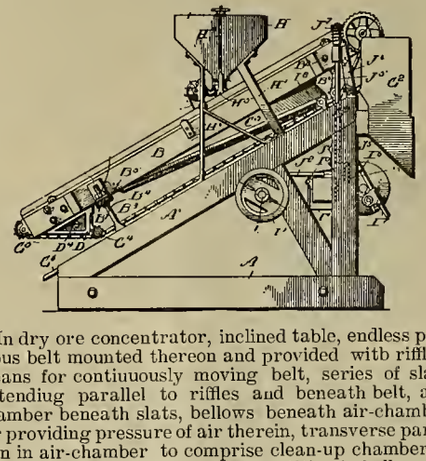
Chlorinating barrel provided with a resistant lining and with channeled rib exteuding lougitudinally, secured to lining and having perforations between interior of rib and barrel, discharge opening communicating with interior of rib, and lateral perforated channeled ribs.

APPARATUS FOR TREATMENT OF ORES.—No. 746,928; O. Daube, New York, N. Y.



In furnace for treating ore, coking chamber, firebox and flues leading from firebox around such chamber; in combination with tuyeres near bottom of chamber and means for supplying air thereto.

DRY ORE CONCENTRATOR.—No. 747,265; H. M. Sutton, Walter L. Steele and E. G. Steele, Dallas, Tex.



In dry ore concentrator, inclined table, endless pervious belt mounted thereon and provided witb riffles, means for contiuuously moving belt, series of slats extendiug parallel to riffles and beneath belt, air-chamber beneath slats, bellows beneath air-chamber for providing pressure of air therein, transverse partition in air-chamber to comprise clean-up chamber in upper end thereof, transverse partition in bellows to form independent air supply for clean-up ehamber, dust hopper at lower portion of table having inlet thereto at lower portion, means for regulating maximum air pressure in clean-up chamber, concentrates hopper at upper end of table, and bearing roller for belt at upper end of table having flexible blades thereon to bear upon belt between riffles.

Mining Summary.

SPECIALLY COMPILED AND REPORTED FOR THE MINING AND SCIENTIFIC PRESS.

ALASKA.

Port Simpson reports say on the Skeena river placer platinum has been found at 60 miles from the coast. A party of prospectors from Port Simpson bas gone to investigate the discovery. The samples exhibited are nuggets as large as walnuts.

ARIZONA.

Gila County.

G. W. Woy of Mesa, president of the Iron Cap M. Co., has men sinking a double-compartmeut working shaft on the Iron Cap mine, near Globe. It is intended to sink at least 200 feet. The Iron Cap M. Co owns six claims adjoining the Copper Hill mine on the northeast.

At the Mineral Farm mine, owned by the Globe M. Co., the double-compartment shaft is down 100 feet and development will be increased.

Graham County.

By February 1st Manager J. W. Benny expects to have tbe second half of the Sbannon C. Co.'s concentrator, near Clifton, in operation.

N. L. Lewis is preparing to increase development on the Irish mine, near Clifton. A tunnel has been driven 115 feet under a heavy outcrop and is expected to cut the ledge tbis month. The group consists of seven claims and is within 2000 feet of the foot of tbe Longfellow incline.

Two 220-ton bins have been built on the Ajax mine, near the foot of the Longfellow incline of the Arizona C. Co., near Clifton. The breast of ore in tbe drift is said to show 3 feet of 15% copper ore.

A. P. Ayling, manager of the New England C. Co. near Clifton, says he will resume development work and will operate eight machines in four places in the mine. It is not yet decided when the company will start work on the proposed railroad from Clifton to tbe mines.

Maricopa County.

(Special Correspondence).—The White M. Co. is taking out shipping ore from its mine, 40 miles west of Phœnix. It is necessary to haul water for camp purposes a distance of 12 miles, but a supply will be developed on one of the claims.——At Wickenburg the smelter has been put in shape for another run.

Tbe smelter at Albambra will make a shipment of copper next week, having been blown in this week, says Superintendent Marlar.——R. E. Humphries has put on more men at work on his property, east of Morristown.——Tbe Lime Creek C. Co. is working men on the Billy Edwards group of claims, near Rogers Springs, in Cave Creek district. High-grade ore is being taken out and shipped to the smelter at Alhambra.

G. Hamlin says he will have a stamp mill in operation at tbe Relief mine, north of Peoria, next week.——The National M. & Dev. Co. is preparing to sink 100 feet on its group in the Wbite Tank mountains. When the shaft is down 100 feet a drift will be run for 150 feet.——H. J. Bennett has put men to work on his claims east of Morristown. Copper ore has been struck.——G. Carguile is developing his claims in Cave Creek district.——The Hercules C. Co. on its group of claims near Morristown has development work under way.——R. S. Slusher is preparing to put men to work on his claims west of Morristown. There is a showing of lead on two of tbe claims.

Phœnix, December 17.

Mohave County.

C. T. Kennan of Martinez, operating on the desert near Signal, is building a 10-stamp mill. The heavy freighting for the camp is done from Yucca, as that point affords a cheaper rate.

The Samoa and Fourth of March mines of the Chloride M. Co. continue weekly sbipments to the smelter. The ore runs $75 net per ton. As work progresses the 12-inch vein in the lower tunnel of the Samoa mine is said to he widening, and the ore is carrying gold values and native silver.

Pinal County.

(Special Correspondence). — A strike made on the Silverado claim of the Golden Quiver group last week shows ore carrying values in gold and silver, the shoot being 30 inches in width.——The J. H. Brown group of four gold claims in Box Canyon district, 18 miles northeast of Florence, has been sold to C. G. Werner and L. Eddy. Development work has been done.

The oil well in Hackberry Wash, near Kelvin, is down 1295 feet, and favorable indications for oil are reported encountered.

The Arizona-Pacific Co. is working three eight-hour shifts in the double compartment shaft and will he continued till the depth of 500 feet is reached.——Preparations are being made to cyanide tbe tailings of the Silver King mill at Pinal.

Florence, December 27.

Yavapai County.

(Special Correspondence).—A body of high-grade copper ore has been opened in the Bisbee Belle mine, near Constellation.——K. Barrett has his mill in Buzzard's Roost gulch, near Briggs, in operation this week.——The Copperopolis road is being put in shape so that ore can be bauled from the Jones mine, near Briggs.——C. W. North is developing a gold-bearing group in Humbug district, near Columbia, on Humbug creek.——F. E. Wager is developing a silver claim near the Tip Top mine, northeast of Castle Creek hot springs.

Phœnix, December 27.

The Verde Chief Co. will start operations on its group next week, and, in addition to other work, will put a core drill to work, making tests at different points.

Repairs and alterations on the hydrocarbon oil burning smelter of the G. A. Treadwell Co. at Mayer having been made, the plant is again in full operation. E. D. Treadwell is superintendent.

Manager G. W. Hull of the Cleopatra M. Co., near Jerome, says the power house which was hurned will be rebuilt.

A bulkhead in one of the levels in the United Verde mine at Jerome is reported to have been opened and the level explored and found entirely free from fire. As to fire, the mine is said to be in better condition than for some time. The grading being done at the United Verde works, south of the smelter, is for a building to be used in connection with the pipe for saving the flue dust from the furnaces. Two pipes will be run from the stack to the building, one to carry the smoke and dust in, the other to allow the smoke to escape.——The Iron King mine is working with 300 men, the United Verde is employing 1500 men and the Copper Chief has 150 men.

ARKANSAS.

Marion County.

Work will be resumed on the Sure Pop mine near Yellville. The Sure Pop is one of the mines that has shipped large amounts of ore, using the river as the channel through which the market was reached.

CALIFORNIA.

Amador County.

At the Bay State mine, north of Plymouth, the work of crosscutting to the main Bay State vein has been finished and the ledge opened up. The present work on tbe ledge is on the 1050-foot level.

At the Bunker Hill mine, near Amador City, work on the 40-stamp mill is progressing and it is expected to have the mill ready to start February 1st.

The Oneida mine, near Jackson, continues in full operation. Much of the ore is taken from below 2000 feet. A winze is being sunk from the 2000-foot level to 2200 feet.

The repairs of the Argonaut shaft, near Jackson, are nearing the water line, about the 1600-foot level. It is not intended to unwater the shaft entirely, but only so much as is necessary to enable the two levels at 1400 and 1600 feet to be worked.

At the Valparaiso mine, north of the Mammoth mine near Middle Bar, near Jackson, surveys have been made for dumping room and for a mill in connection with it, at the outlet of the Valparaiso tunnel.

At the Climax mine they have put up a 2-stamp mill and expect to start crushing ore this week. The Climax was formerly the Reed & Askey mine, and is near Wieland.

Calaveras County.

The Southwestern tunnel, above Angels, will again he worked during this winter.——The Ozark mine will be unwatered and reopened.

The Empire mine, near Hodson, is again in operation.

It is reported the Demarest mine, near Fourth Crossing, will be reopened.

Work has been resumed at the Royal Con. mine at Hodson with non-union men.

A core drill is in operation at tbe Sultana mine at Angels.

At the Rooney blue gravel mine, near Mokelumne Hill, development work continues, while the mill is crushing steadily.——The Buffalo blue gravel mine, adjoining the Rooney, has been closed down temporarily, hut the pumps are kept in operatiou and it is expected work will be resumed this month.

At the Blue Jay Point gravel mine in the Dell Orto ranch, west of Mokelumne Hill, work is in progress. A tunnel, 220 feet long, has been cleaned out and equipped with steel rails and cars. Sluice boxes are in position; a reservoir has been built, and work in the gravel has been started. The channel in this mine is said to be the same as that of the Stockton Hill mine. This mine is heing operated hy M. Cohen, M. Peterson, J. H. Alcaraz and E. Crilly.

Nothing is being done at the Rough Diamond gravel mine in Tunnel ridge at present, but it is expected work will start this month.——The What Cheer mine is working men steadily. The gravel shows good prospects, says Manager Birch, and it is proposed to put in heavier machinery.

The 8-stamp mill at the Salvator mine, near Mokelumne Hill, is crushing ore steadily.——The Kenross mine is closed down temporarily. J. T. Thompson is manager.

The Stockton Hill M. Co. reports work continuing at its mine near Mokelumne Hill. Operations are going ahead in three directions underground. A drift leading west, or down the channel, has been cleaned out and retimhered for 200 feet, another on the south rim for 300 feet, and a third, east or up the channel, 230 feet. Pay gravel is showing. It is expected work will start on the Clover Leaf mine next week, shortly after the new year, and also on the Hexter. Four thousand feet of a trench have been dug from the flume of the water company, at a point near Nigger Hill, to the mine, and laying the pipe is in progress. This pipe will carry water to tbe mine for the batteries of the mill and other purposes.

The Emma quartz mine, near Valley Spring, has twenty men at work sinking the shaft, which has reached depth of 460 feet, and it is intended to go to the 500-foot mark. A station will be cut at the 400-foot level and drifting on the ledge started. The company has bought the Birdena mill and machinery at Campo Seco, which will be set up at the Emma.

Men are at work at the Neverthought mine, near Jesus Maria, under T. E. McSorley, preparing for further development.——Work has started on the Lamphear mine, soutb of Mokelumne Hill, and a hoist will be put up for a vertical shaft, which will be sunk 1000 feet.

J. B. Maguire, E. Zumwalt and W. G. Morris have started work on the French Hill mine near Mokelumne Hill. A ditch taking water to the mine has heen dug and machinery is being put in position.

El Dorado County.

Waggoner Bros., interested in the claims south of the Havilah mine at Nashville, having bought the Aaron Ball gravel claims at Indian Diggings, report striking pay gravel in the latter.

A. N. Bucbanan is opening up the Smith Point, or Zantgraft extension mine, near Loomis.

Inyo County.

J. A. Wauchope, manager of the Nobles mines and the Encinitas copper mines, at Encinitas, San Diego county, reports having hought twenty gold claims, 85 miles from Daggett and near Death Valley.

Kern County.

The Pinmore mill at Johannesburg has been rebuilt and is in operation. Some of the machinery of the mill whicb was burned, after being heated and straightened, was used again, says the Randsburg Miner.

The Nevada County Oil Co. and the Black Jack Oil Co., at Kern river, near Bakersfield, are resuming operations after a suspension.

It is expected the King Refining Co. will enlarge its oil refining plant at tho Kern river field, near Bakersfield, to double its present capacity, says the Californian.——The Southwestern & Eastern Con. Co. plant is nearing completion.

Nevada County.

F. H. Hall has bonded the Hughes interests at Shady Creek, near Nevada City, with an option to buy. This addition will give Hall 3 miles more of territory for mining and in tbe spring he will put in more machinery and increase the number of men to thirty.

Plumas County.

At Laporte the Claybank mine is again driving the main tunnel ahead. When the shaft was reached it was found the pressure of debris in it was too great to work or hold with safety, and it was concluded to bulkhead that part of the tunnel and start anew to one side, says the National-Bulletin. It is expected that when this tunnel extends a few hundred feet further gravel will be found. Reports from tbe Bellevne mine say tbe gravel is becoming less troublesome to handle. Difficulty has been experienced on account of tbe amount of water, causing the loss of a number of gangways.

A. R. Smith and W. Venning have a bond on the Savercool group of mines on the North Fork, near Quincy. This mine has been developed by several tunnels run on the vein and connected by raises. A stamp mill plant is on the mine. Smith & Venning will retimber the tunnels.

San Diego County.

The suit of F. F. Wright et al., against Tannenbaum & Co. of New York and the Himalaya M. Co., owners of the tourmaline deposits in the Mesa Grande country, has been settled. F. F. Wright et al. were owners of the Sancho Pancho and other mines, and claimed that tbe Tannenbaum claims overlapped theirs and were being worked to their detriment. They brought suit to enjoin further trespass, and also for damages. Papers filed this week indicate that a settlement has heen brought about by the Himalaya M. Co. buying the claims of the plaintiff outright for $6000.

Shasta County.

J. L. Cannon of French Gulch has taken a bond on the Ellery Bros. mining property, near French Gulch, for one year for $8000. The group consists of the Three Sisters, Afterthought et al. claims in French Gulch district, together with a Huntington quartz mill. Cannon must keep men at work continuously, and give the owners 10% of the gross receipts of the ore.

Sierra County.

Manager Mather says the vein was struck last week in the Oriental tunnel below Alleghany. Tbe ledge tapped is in 3380 feet from the mouth of the tunnel, and there is a flow of 8 inches of water from the fissure, being the first water struck in tbe tunnel. Mather states it is thought the vein is the Alta ledge, in which event tbe Oriental vein will bo reached further on.

Siskiyou County.

The Spengler claim at the mouth of Humbug creek, near Hawkinsville, is being mined, with a good supply of water in Humbug creek, says the News. Ground sluicing and hydraulic operations are carried on extensively, and a steam derrick raises the boulders found in working to bedrock. The claim is expected to he worked steadily until late in the coming summer.——Manager Draper, of the McKinley quartz mine, on Humbug creek, has leased railroad lauds near the mine for use of timher thereon, and has fifty men building mill, tramways and tunnel ing.

Tuolumne County.

The Tuolumne Chief Con. G. M. Co. has been incorporated, with F. Danford, A. C. Sweet, L. D. Bothwell, A. R. Sweet and W. N. Jamison of Los Angeles as directors, to operate in Tuolumne county.

J. W. McGinn has bougbt the Golden Thread quartz mine, ¾ of a mile from Algerine.

The Magnet says there is a revival of pocket mining on Jackson's Flat, near Tuttletown.

The Goldwin M. Co. has transferred its holdings for $3000 to T. G. Hillhouse, G. W. Casper, H. D. Downs and C. E. Miller of New York, trustees under agreemeut for reorganization of the Goldwin M. Co. The transfer includes all personal property on the Philadelphia, Rhode Island and Boston claims, near Carters.

The Telegraph Line claim, on the main Tuolumne river, below the Mohican mine, near Groveland, is reported bonded to E. M. Wilkinson for E. A. Wiltsee of London, England, part owner in the Providence mine, near Carters.

The New Era (or Hunter) mine, near Carters, has heen bonded to T. F. McAvoy of San Francisco, manager of the Hardtack G. M. Co., which owns, also, the Hardtack mine and its extensions, the Plateau and Chilcoot Pass quartz mines. Both gronps have mills, the Hunter a 10-stamp and the Hardtack a 2-stamp. The Hunter has extensive water rights on tbe Hunter Canyon creek, and is operated entirely by water power, as is the Hardtack.

At the Don Pedro mine, south of Cbinese, a vein running 2 to 10 feet wide, carrying value of $11 gold per ton, is being opened up, says Manager W. McClintock. The main shaft has reached depth of 125 feet and drifting will he run to 116 feet. —— H. B. Stewart and T. F. McGovern have bonded the Golden South mine at Ball Rock, near Confidence (formerly the Old Ohio mine).

Drifting is progressing east and west from tbe 200-foot level in tbe Del Monte mine, near Groveland. Toward the west the run will reach 257 feet and then a raise will be made to connect with tho shaft. The hoist will be in operation this week and the mill will be completed by the 15th inst.

Operations are again under way at the Hull mine, 4 miles from Groveland, says A. L. Froehlich.——The Big Casino M. Co. mill is running steadily, the mining capacity being 100 tons daily. The tramway from the Two Brothers mino being completed, ore will be run to the mill from that shaft.——It is reported operations will be resumed at tbe Duleek mine by Manager W. J. Graham. The Duleek is equipped witb hoist, engines, boilers and mill.

COLORADO.

Boulder County.

(Special Correspondence).–Eldora, so far as organization is concerned, is a non-union camp, and the following scale of wages is paid: $3 a day, minimum, to laborers for eight hours. The Con. C. M., M. & S. Co. pays machine men $4 per day; helpers, $3.50; muckers and trammers, $3; blacksmiths, $4 and blacksmith's helpers, $3.50 per day of eight hours, board being $4 per week. The Denver Tunnel Co. pays $3.50 for machine men, $3 for helpers, and $2.75 for trammers, with board at $5 per week. The United States Gold Corporation has four men at work paying each $3 per day of eight hours and board. Formerly when the union was in control in the camp nine hours constituted a day's work, with a minimum wage of $2.75, and maximum at $3.50.

Eldora, December 27.

(Special Correspondence).—The mining industry in and around Ward is improved over one year ago. Several additional properties have opened up and are doing considerable work. At, the Struggler mine, 3 miles north of Ward, a 50-ton concentrating mill is being built. On this mine they have 2000 feet of development work done. They have seven claims in one body. The shaft is down 310 feet and the tunnel is 762 feet in length, besides three other levels opened up. The ore will average $10 per ton in gold and copper. G. Mitchell is manager and E. A. Smith superintendent.

Ward, Dec. 26.

Chaffee County.

The Buena Vista S. & R. Co. works at Buena Vista were closed last week, partly because of lack of ore from the Mary Murphy mine, and the indications are that the plant will not be opened before spring. Meantime development work will be continued in the mine and improvements made till sufficient ore has been blocked out to continue operation of the smelter. For the past five years the smelter has been operating on Mary Murphy ore only. It has been found, says the Republican, that a large per cent of the values have been escaping in the fumes, and it is given out that the closing down is for erection of a load furnace to treat the ore coming from below the oxidized zone. The operation of the smelter has been conducted by power from the Arkansas river, with help of two (gasoline) 60 H. P. engines, and as the water power has fallen below the regular level, necessitating operation of the engines night and day, the expenses could not be met by treatment of such low-grade ore, says Manager Hinkson.

Clear Creek County.

(Special Correspondence).—During the past few months W. Cooper, manager of the Capital M. & T. Co., has been sinking a shaft and has struck a flow of water in the mine. He is lifting eleven tons of water per hour; but, with the volume of water he has had to handle, has sunk the shaft at rate of 50 feet per month.

D. Kennedy, owner of the Centennial G. M. Co., has a small volume of water to contend with and has opened up a vein of high-grade gold and silver ore. The mine continues producing a good tonnage each month.

Difficulty is being experienced in securing a jury satisfactory to both sides to try the Sun & Moon conspiracy cases. The Sun & Moon transformer house at Idaho Springs was blown up in July, and several striking miners were arrested as being implicated in the affair. J. E. Chandler, secretary of the Idaho Springs Miners Union, was charged with being one of the leaders in the affair.

Georgetown, Dec. 27.

Colorado Springs and Eastern men have bought 300 acres of the Clear Creek placers and have options on the balance of the J. B. Adams holdings, in all 1000 acres. The property comprises the creek bed and flat land on either side, beginning 2 miles above Golden and extending down the creek. Examination was made by the use of a steam drill, employing a 6-inch casing and sand pump. Bedrock was found at 30 feet below the surface. The price paid was $500 an acre. Gold dredgers—at least three—will be put in and will be under the management of H. J. Rolling.

The Laffey Bros. lease on the Narragansett mine, located above Silver Plume, has been taken over by Silver Plume men. An 18-inch streak of mineral was opened in the tunnel last month which is reported to give returns of 300 ounces in silver. Operations are to be increased by the East Argentine M. Co., says Manager Sidney. A plant of machinery will be put in as soon as the weather will permit of its transportation to the mines.

Custer County.

The Flag M. & M. Co., owning seventeen claims near Rosita, has given a bond and lease to the Blunt Bros. of Florence, who have put men to work on development. A strike of copper and horn silver ore was made on the group last month. The seventeen claims are adjoining and are near the Bassick mine.

Work on the Humboldt mine at Rosita is progressing and more men will be put on, and production resumed. The shaft, which is 800 feet deep, is said to be filled up with 125 feet of debris. This is being unwatered and cleared out.

Dolores County.

The supply of water in Silver Creek is becoming limited and the starting up of the mill at the mouth of the Group tunnel, near Rico, will be delayed until after a heavy snowfall, which would, in a measure, protect the water from freezing in the flume, says the Rico News.——No zinc concentrates were shipped from Rico district during the past year, but it is expected the zinc concentrator will be again started up by spring.——The Atlantic Cable mine is blocking out a body of tin ore.

Fremont County.

It is reported that Manager Hower of the Dorcas mill at Florence, who discharged all of his employes who belonged to the Western Federation because of the threat of the Cripple Creek Mine Owners' Association to shut off his ore supply if he did not, was notified this week by the owner of the Morganstein coal mine that no more coal could be procured for the mill at that mine. The coal miners had threatened to strike if the Dorcas was given coal. The Morganstein is one of the mines that acceded to the demands of the union men.

Gunnison County.

The estimated output of the county for 1903 is as follows:

Coal and coke	$2,500,000
Metals	350,000

Hinsdale County.

Tests made on the ore body of the Pelican mine, near Lake City, are said to show values of $200 per ton. Besides this, there is a large amount of milling grade ore. Development work will be increased.——In the Monte Queen, Buckeye and Nellie M. mines, being operated by a company of which W. E. Mendenhall is local manager, there is a streak of high-grade ore opened in the breast of the tunnel. Above the tunnel there are 300 to 700 feet of stoping ground. There are also 1000 tons of milling ore on the dumps, and by spring it is expected there will be enough on hand and opened up to warrant building a mill.——H. H. Lynde, superintendent of the White Dollar mine at White Cross, has taken in winter supplies and will continue sinking the shaft on the vein to a depth of 100 feet.

Lake County.

The Roindeer shaft on Rock hill, near Leadville, was added to the producing list this week. The Reindeer has opened up an ore shoot on Rock hill, farther to the southwest, than any previously shown. The ore was first opened in the shaft 375 feet from the surface, and was followed for 6 feet. It is a lead carbonate of good grade, says the Carbonate Chronicle. Fifty feet below this another drift was started and 50 feet farther down another one is under way. A cage has been put in, ore bins built, and other preparations made by Manager G. F. Campion. The Reindeer Co. is owned by J. F. and G. F. Campion, W. B. Page, T. F. Daly and K. L. Fahnestock.

A strike was made last week in the new Cleveland shaft of the New Monarch M. Co. near Leadville. Assays of the ore are said to show two ounces of gold and 100 ounces of silver. The shaft is down 340 feet and the ore is still in the bottom.

Las Animas County.

Trinidad reports say while there is no visible change in the coal strike situation, there is a decided feeling that a resumption of work is to be looked for within the next two weeks. Thus far the C. F. & I. Co. has made no decided effort to open its Trinidad mines, but has taken to Primero and Tercio such men as it could find in Trinidad who wanted to go to work. Primero had forty-five men at work on the first day of the strike. Last week it had 220 diggers at work and the daily output of coal is 1500 tons. Meantime there come complaints from all over the district relative to the condition in which the strikers find themselves. Another fact is a report that the general commissary store which the officers of the union had planned to establish in Trinidad has been abandoned. The expense of maintaining the strike, which for supplies alone has amounted to a considerable sum, has been a heavy drain on the union resources, and with the proposed cut in miners' wages in the East and some probability of its resulting in labor troubles there, a curtailment of expenses has seemed advisable. The allowance for supplies by the union is $2 a week throughout the district for single men and $3 for married men. Earlier in the strike they were getting $5 and $8. This allowance is not satisfactory to the miners.

Mineral County.

The East Willow M. Co., near Creede, is preparing to sink a shaft below the main tunnel level, and a station has been cut 3000 feet from the mouth of the tunnel on the Ethel claim, one of the four claims connected and operated through the main tunnel. A hoisting plant will be set up, compressed air to be used for power. Above the main tunnel level is a body of lead and zinc ore, and the mill continues handling fifty tons per day concentrating ore that has been taken out in doing development work.

Ouray County.

A tunnel will be run next summer from a point low enough to drain the Guston mines at Ironton, says the Standard.

Pitkin County.

The Bimetallic and Aspen Contact companies, operating near Aspen, have been consolidated, embracing between 200 and 300 acres. The properties have been taken over by J. J. Hagerman and D. J. Hyman and the Aspen-Bimetallic M. Co. incorporated. H. Sayre is manager.

San Juan County.

The past year has been an active one in San Juan county, says the News. The production will show an increase, notwithstanding several mines were idle during the year that were producers during 1902, due to the uncertainty of labor conditions in other sections of the State. During the year 1903 over 40,000 feet of underground work was accomplished, costing from $3 to $20 per foot. Of this amount the principal mines furnished as follows:

Mines.	Feet.
Silver Lake	9,000
Gold King	530
Mogul	3,980
Henrietta	2,600
Sunnyside	2,500
Highland Mary	1,200
Astor	1,500
Royal	1,200
Anglo-Saxon (G. W. King Co.)	1,200
Benson	1,000
Green Mountain	1,000

Besides these many other mining companies have driven from 500 to 700 feet during the season.

San Miguel County.

D. Swickheimer of Denver of the Japan M. Co., near Telluride, reports that this month his company will resume operations at the Japan mine in Savage basin. The work until spring will consist chiefly of development. Since the Japan vein was cut by the lower crosscut tunnel no work has been done at the mine. Drifts will be run both ways from the point where the lead is cut and a raise driven from the lower crosscut to the upper working level of the mine. Later, a mill will be built near the Smuggler-Union plants at Pandora, and a tramway connecting the mine and mill will be built.

Summit County.

Machinery for the concentration mill of the Quandary Mountain M. & M. Co., near Breckenridge, is on the ground and is being placed. The flat or "blanket" vein of ore has been opened up for 60 feet along the breast and shows the deposit 4 to 8 feet thick, says Superintendent Nance.

The Clark-Reithmann (Goldrick) property in French gulch, near Breckenridge, has been sold to W. Lennox for $17,050. The mine has been idle for several years and will be opened to lessees.

At the Jessie mine and mill, near Breckenridge, T. R. Griffith and A. Matthiessen have taken charge. The mine and the 40-stamp mill are being put in shape for further development. Men are at work repairing the tunnel. Considerable retimbering will be required in the older workings. There are several miles of tunnels and drifts, with stopes and raises, says the Times.

Teller County.

Engineer A. C. Jaquith's measurement last week of the flow of water of the El Paso drainage tunnel at Cripple Creek showed no change from the preceding week, the flow amounting to 5130 gallons per minute. The reason there was no increase in the flow is that there were no men at work in the east lateral during the entire week. The mines are being unwatered at the rate of 6 inches per day, and at this rate it is expected the Elkton, Mary McKinney and several other properties can be worked in the lower levels before spring.

Railroad reports estimate the output of Cripple Creek camp for month of December at about the normal figures which prevailed before the strike. The total output for the year 1903 is expected to reach a value of $18,000,000. The tonnage for November was 32,000 tons, and it is estimated December figures will show 50,000 tons.

The annual report of Manager W. F. Rock of the Gold Sovereign M. & T. Co., operating at Cripple Creek, shows the property of the company is being operated by three sets of lessees, all of which are producing ore. The Jackson shaft is 625 feet deep and is leased until Feb. 1, 1905, to the Cripple Creek Gold Temple M. Co. During the past year this shaft, which is the main working shaft, has been sunk from 550 feet to the 625-foot point. Ore has been produced continually from this shaft of a gross value of $25 per ton. There have been three levels extended from this shaft. The fifth level was extended 25 feet additional, which took it to the south end line. At a point 190 feet from the shaft ore was opened and extended 53 feet to the south end line of the location, with an average width of 6 feet by 120 feet high, with ore still extending upward. The seventh level at depth of 625 feet is the bottom of the shaft. A level has been extended south 200 feet from the shaft and 30 feet north of the shaft, but no ore is showing as yet. The lessees on this block are required by the terms of their lease to start sinking another 75-foot lift on Jan. 1, 1904, and to complete the sinking of the shaft to the 700-foot point by April 1, 1904. —— The Whisper shaft is 375 feet deep. No sinking has been done during the past year. Some development work has been done and some ore produced, but this block is nearly all stoped out above the bottom. It is proposed to re-lease this block for another year as soon as the present lease expires, Jan. 7, 1905, requiring the lessees to sink the shaft immediately an additional 100 feet. This block is too remote from the main workings to allow it to be operated at present from that shaft. —— The Rowson shaft has been completed to the 430-foot point by G. Lenecke & Co., who hold a lease on this block running to Feb. 1, 1905. No ore has ever been produced in this block below the 200-foot level.

The Vindicator mine, at Victor, is shipping out ore from all its levels but those under water. There are 100 men in two shifts. The company is producing fifty tons of ore per day, and the values average 1.5 ounces in gold to the ton.

The annual report of the Acacia G. M. Co. of Cripple Creek shows that the company is still operating its properties by the leasing system, there being seven leases in active operation. During the past year considerable development work has been done and several new ore bodies have been opened up. Following is the statement of ore returns for the year ending November 30: Morning Star claim, block No. 1, 652 tons, $4464.81 in royalties; Burns, block No. 1, 166 tons, $665.74 in royalties; Burns, block No. 3, 264 tons, $1168.90 in royalties: Burns, block No. 5, 238 tons, $2223.12 in royalties; total tonnage, 1321; gross value, $49,167.33; net value, $33,857.82; royalties, $8522.57. J. Hundley is president and K. McKenzie vice-president and manager.

The Empire State Con. G. M. Co. has bought the Phœnix lode holdings of the Orphan Bell Co. The Phœnix claim is east of the Wilson and the Free Coinage Co. and north of the Trachyte, on Bull hill, Cripple Creek, and measures one acre. It is under lease to W. J. McChesney and three associates. They have sunk a 50-foot shaft and are developing an ore body 18 inches wide, from which they are saving ore of medium grade. The addition of the Phœnix brings the holdings of the Empire State Co. up to twenty-one and one-half acres.

There are being employed on the Stratton's Independence, Ltd., mine at Cripple Creek an average of 475 men. Production varies between 200 and 225 tons per day, the ore coming for the most part from the upper levels.

The Acacia G. M. Co. of Cripple Creek has issued its annual report for the year ending Nov. 30, 1903, showing seven leases in operation, from which fair results have been secured, says the Republican. The total production for the year was 1321.17 tons, of a gross value of $49,167.33. The net value was $33,857.82, the company's royalties amounting to $8522.57. The royalties average 25%. The company's principal claims are the Burns and Morning Star, covering twenty patented acres on Bull hill. The gross production to date approximates $400,000.

IDAHO.

Blaine County.

S. Shaefer has bought an interest in the Horn Silver and Last Chance mines near Arco, on which he and O. B. Floischer have a bond. Shaefer says they have opened up a vein showing horn silver ore, running 300 ounces in silver per ton. There is a copper vein on the mine which will also be developed.

Boise County.

The Golden Rod M. Co. last week made its final payment of $21,500 on the Mineral Hill group of seven claims near Placerville, including mill site, water rights and a 5-stamp mill. In addition to this is in-

cluded two groups in Thunder Mountain district—the Excbange and Brooklyn.

Lemhi County.

Control of the Ima M. & M. Co., operating at Patterson, has been taken over by New England men, and J. W. Taylor of Columbus, Ohio, is manager. A 100-ton concentrator will be built and development work in the mine increased.

Shoshone County.

C. C. Groesbeck, manager of the Beartop M. Co., near Murray, says the company is preparing to ship ore which is blocked out as soon as the roads are passable. The Monarch also will make shipments from the upper tunnel, and the Terrible-Edith is taking out galena which is to be shipped during the winter.

Tbe Hypotheek lead and copper mine, near Kingston, has put in a compressor and is sinking its shaft with power drills. The property has been mainly developed by tunnel. Peacock copper and high-grade lead ore have been taken from the mine. —— The Lombardy M. & M. Co., 1 mile north of Kellogg, has men at work drifting on the ledge in 750 feet, with a drift of 450 feet. The face of the tunnel, 27 feet across the ledge, is said to assay 30% lead, with values in silver, copper and gold. P. Albinola is president.

MICHIGAN.

Houghton County.

Fire in No. 1 shaft of the Isle Royale mine, near Houghton, imprisoned and suffocated three men last week. The fire broke out about noon, with 1400 men underground. Fire doors were closed, cutting off the workings in No. 2, and men were warned to flee for their lives. The entire shaft, ucarly ½ mile in depth and heavily timbered, was afire. Water poured into the top merely kept down the fire for a hundred feet or so below the surface. The bodies of the three men were found the following day by a party that descended the old Grand Portage shaft at the north limit of the mine. Gas filled the mine around No. 1 shaft and the old timbering is all gone in the Grand Portage shaft. No. 2 Isle Royale shaft is expected to be supplying rock this week. In the week previous to the fire several additional drills were put to work at tbe Isle Royale mine and driftiug was underway on several of the lower levels; rock shipments averaging 950 tons daily with production of refined copper being maintained at rate of 150 tons a month. The rock yields an average of fourteen pounds of copper per ton.

Ontonagon County.

The Victoria mine is approaching the 21st level, although the plat at the 20th was only finished Nov. 18th, says the News. The work of sinking the main shaft for the bydraulic compressor is under way; dimensions, 20x20 and 300 feet deep. Three auxiliary circular shafts will be put down by drilling with a device built on the ground.

MISSOURI.

Jasper County.

The mines and mills of the Zinc Miners' Association of Joplin district resumed full operations last week after three weeks' shut down, the curtailment policy having had tbe desired effect of improving the market conditions.

C. W. Arbuthnot, W. H. Howard and T. L. Brown have incorporated the Hermit M. Co. to operate near Joplin.

B. Pepper of Webb City has a 60-acre lease on the G. Wilmoth farm, near Webb City, and at 10 feet struck jack in a drill hole, and at 25 feet the drill went into lead. ——A. R. Caulkins last week started the Yellow Dog mine on full time after being shut down eighteen days. He kept all his men at repairing, etc.

Lawrence County.

At Stotts City, C. Sprinkle and J. Stotts have sunk a shaft in the north part of the city to depth of 20 feet, and have developed a body of fire clay. The last work shows mineral indication with "shines" of lead. —— J. B. Davis moved his prospecting machiuery from the Shipman land to a shaft on the Albert Wbite land last week. This is a shaft sunk several years ago to 100 feet.

The Randolph M. Co. has been incorporated to operate a lease on forty acres of the Quinn land adjoining the Golden Rod mine, near Joplin. Several drill holes on this forty-acre lease are said to show the same formation as has been developed by the Golden Rod. They are having the forty acres platted, and as soon as same is finished work will start on a number of shafts, as they have several applications for sub-leases, says the News-Herald.

MONTANA.

Fergus County.

R. E. L. Townsend et al. have bought a group of properties ou Gilt Edge peak, betweeu the Gold Reef and Chicago & Montana mines, near Gilt Edge. Men are at work upon the group and development will be continued during the winter.

Madison County.

J. N. Kirk and W. Owsley et al. of Butte have incorporated the Walker-Penn M. Co. to develop a group near Twin Bridges.

Silver Bow County.

The Raven M. Co., developing the Raven mine, is sinking a 1000-foot shaft and expects to strike a body of copper-silver ore before the 1000-foot mark is reached. The shaft has cut the iron capping which is claimed to be the dividing line between the gold-silver ores and the copper-silver zone of the Butte copper belt. This capping is 125 feet thick, and so far as mineral is concerned is practically barren. The shaft is down 550 feet deep. From the surface to the point at which it struck the iron capping gold and silver ore was taken out (the shaft being sunk on the vein). W. W. Morris of Pony and J. W. Forbis, J. Berkin and C. Mattison of Butte are principal owners.

NEVADA.

Nye County.

The mill of the Midway M. & D. Co. of Tonopah has been put in operation. There are 1000 tons of Midway ore on the dumps which will be milled.

J. H. Sullivan, J. Gleason and P. B. Kotelman have bought a half interest in the Dryland Sailor M. Co., whose claims adjoin the Bob Tail claim and are near the Golden Anchor.

A company has been organized to operate a group of claims at Timber Hill by P. Smithmyer, H. H. Clark, L. E. Benson, A. K. Clark, J. F. Hemen and M. M. King as directors. Developments have shown ore carrying gold, silver and copper values. Machinery will be put in.

It is reported the Tybo M. & R. Co. has suspended operations at Tybo, and that attachments and liens had been levied against the company's property at that place for $8000. It is thought the trouble is only temporary and that work will be resumed next month.

NEW MEXICO.

Grant County.

Ten cars of high-grade ore are being shipped every thirty days from the Monument Key mine at Pinos Altos by W. C. Chandler, says the New Mexican. He has twenty-five men employed iu developing the mine and taking out ore. This number will be increased to fifty men. In the past six months 400 feet of drifting on the 700-foot level has shown the vein of ore to be continuous, and the copper, silver and iron values equal tbe gold it contains.

OREGON.

Baker County.

The 10-stamp mill of the Snow Creek mine, 1 mile from Greenhorn, is in full operation.

P. D. Healy, managing owner of the Grizzly mine, on McCulley's Fork, 5 miles from Sumpter, has resumed operations.

Operations have been resumed at the Carpenter Hill mine, Pocahontas district, near Baker City, says E. A. Milks of New York, manager.

Crook County.

(Special Correspondence).—Superintendent J. Wood of Ashwood reports he has completed 80 feet of drift on the 200-foot level of the Red Jacket mine, and that he has cut a 5-foot vein of good ore. The Red Jacket is a few miles east of the Oregon King mine, which has opened a 4-foot body of ore, specimens of which assay $60,000 per ton. The King is sinking below the 500-foot level, a heavier hoist having been put in.

Ashwood, Dec. 28.

Grant County.

A hoist has been set up on the Indiana mine, near Prairie City.

SOUTH DAKOTA.

Lawrence County.

The Hidden Fortune G. M. Co. is running its cyanide plant near Lead City and treating an average of 200 tons of ore per day. This plant started on fifty tons a day and with twenty stamps dropping. It is being increased to 300 tons daily. The ore is delivered over the Burlington and Northwest railroads, which involves a haul of 5 miles, all down grade. The ore runs $20 per ton in gold. Both amalgamation and cyaniding are used.

The Golden Crest M. Co., near Deadwood, continues dropping ten stamps and crushing daily fifty tons. The company experienced difficulty in melting its product from the zinc boxes, says the Lead City Call, owing to large amount of sulphates, and after reducing to bullion less than a quarter of the precipitates, were obliged in the interest of economy to abandon the usual metbod of melting and throw down the gold by addition of litharge to the flux. This produced a lead matte wbich was not marketable at the United States assay office, and the company has consequently shipped the matte, together with 1000 pounds of rich slag, to a Denver, Colo., refinery. Owing to coal shortage the company has been obliged to hang up at intervals during the past month. Development in the mine is progressing and ore is being taken from five different faces. They are mining rock averaging $15 gold per ton. The ore is being taken from several shafts, varying in depth from 85 to 125 feet, sunk on the divide between Two Bit and Little Strawberry gulches. The company is preparing to unwater the double-compartment shaft at a point on the Two Bit side, 1200 feet below the top of the divide. At the bottom of this shaft, which is 200 feet in depth, the vertical veins of ore will be opened and followed in a southeasterly direction toward the divide, where a depth of 400 feet from the surface will be obtained. The completion of this work will increase the output of the mine so that an enlargement of the mill will be necessary, and the company expects to add twenty stamps to its plant in the coming spring.

The main shaft of the Columbus Con. M. Co., in Sawpit gulch, near Deadwood, is down 500 feet and a crossent started to open up the vein west of the shaft at that level. The main vein showed a width of 247 feet at the 200-foot level. At this depth the Columbus vein carries values of $2 to $8 per ton, and 300 assays from samples taken while work was in progress on this level gave average of $4.96 per ton. The two other veins cut on this level show ore of lower grade.

J. S. Ford et al., of Chicago, Ill., have bought the property of the Cooper G. & S. M. Co., near Galena, for $45,000. They will begin development in the spring.

UTAH.

Utah's mineral production, says the Denver News, began in 1864, and up to 1871 the output consisted largely of placer gold, coming mainly from tbe gravels of Bingham canyon. Prior to 1871 there are no statistics to indicate the production, but estimates place it at less than $1,000,000. From 1871 to 1875, inclusive, the Government compiled statistics which show the production of those five years to have been $20,558,079. Copper did not enter into the production of metals until 1873. The State statistician has obtained figures as far back as 1877, to represent the State's output in gold, silver, lead and copper, which are included in the following table:

YEAR.	Gold.	Silver.
1880	$ 165,773.40	$ 4,029,501.30
1890	699,700.17	8,492,209.44
1900	4,263,414.87	6,248,610.07
1901	3,945,303.57	6,801,816.18
*1902	3,972,235.41	16,391,804.97
**1903	4,000,000.00	20,000,000.00
1877 to 1903 inc.	$34,564,459.12	$180,000,336.27

YEAR.	Lead.	Copper.
1880	$ 786,065.97	.....
1890	2,098,766.51	$ 76,536.00
1900	3,122,863.25	2,514,597.46
1901	3,210,967.50	3,750,247.32
*1902	4,500,698.15	3,017,415.06
**1903	5,000,000.00	5,000,000.00
1877 to 1903 inc.	$51,563,589.61	$ 17,947,859.76

Year.	Aggregate.
1880	$ 4,981,340.67
1890	11,367,212.76
1900	16,149,485.65
1901	17,708,334.57
*1902	27,882,153.59
**1903	34,000,000.00
1877 to 1903 inclusive	$284,076,656 82

*From Government Assayer at Helena.
**Estimated.

Salt Lake City reports show tbe ore and bullion market settlements for the year aggregate $22,591,322, as against $20,073,616 in 1902. These figures do not represent the complete output, for the reason that it is difficult to account for the ores and bullion shipped to market outside the State. The settlements by months for 1903 were:

January	$ 2,036,810
February	2,039,500
March	2,784,479
April	1,341,221
May	1,561,300
June	1,604,510
July	1,829,250
August	1,771,550
September	1,905,212
October	2,050,305
November	1,667,095
*December	2,000,000
Total	$22,591,322

*Estimated.

Beaver County.

The Lenora group of nine claims, in Star district, near Milford, has been taken over by I. D. Carpenter, P. C. Evans and J. Ingebretzen of Salt Lake, and M. L. and W. J. Burns of Milford. The Lenora group is located in Elephant canyon, near the Elephant, Talisman and other mines. There is a vein of silver-lead ore exposed.

Manager C. Baxter of the Kittie Cliff mine is arranging to build a mill on his holdings. The Kittie Cluff is near the Vickshurg mine of the Majestic group, near Milford, and has been developed to a depth of 250 feet, showing ore with values in gold and silver. The plant will handle the ores by cyanide process.

Juab County.

Work is in progress on the Ralph claim in East Tintic, uear Eureka, by M. M. Kellogg.

The Carisa mino of Tintic, near Eureka, which was temporarily closed down to repair its boilers, will resume this week.

The table given below shows an increase for Tintic district for 1903 of 95,770 tons over 1902, and when the product from the mines for month of December is added the showing will he further increased. The Grand Central, Centennial-Eureka and Dragon Iron mines marketed one-half of the entire amount. The Gemini and Mammoth were also heavy shippers during the year. The shipments from four of the largest in the district—the Centennial-Eureka, Bullion-Beck, Gemiui and Bullion Hill mines—were curtailed on account of the underground fire in the last-named mine in August. However, the Centennial-Eureka Co. put men at work shipping low-grade ore which had been accumulating on the dump and in this way the output from the mine during that period was about normal and the smelter at Bingham Junction, of the United States M. Co., was also kept in operation. The advance in price of silver, lead and other metals during the past year made it possible for the mine owners in Tintic section to market ore which two years ago they could not have handled at a profit. Legal difficulties and a suspension of work at the Centennial-Eureka mine pending erection of the smelter caused output for year 1902 to be lighter than it would otberwise have been:

ORE SHIPMENTS FOR 1903.

Name of Mines.	No. Cars.	No. Tons.
Ajax	39	1,170
Bullion Beck	220	6,600
Black Jack (iron ore)	161	4,830
Centennial Eureka	1,481	44,430
Carisa	115	3,450
Dragon Iron	931	27,930
Eureka Hill	86	2,580
Eagle & Blue Bell	67	2,010
Gemini	427	12,810
Grand Central	1,033	30,990
Joe Bowers	3	90
Lower Mammoth	155	4,650
La Clede	20	600
Little Chief	3	90
Mammoth	392	11,760
Mordue (iron ore)	1	90
May Day	17	510
Martha Washington	23	690
Noon's Iron	65	1,950
Rising Sun	1	30
Richmond & Anaconda	2	60
Rabbit Foot	1	30
Star Con	92	2,760
Swansea	42	1,260
South Swansea	59	1,770
Uncle Sam	90	2,700
Victor	124	3,720
United Sunbeam	15	450
Whiting (iron ore)	4	120
John Moore (Tesora lease)	1	30
Tetro	30	900
Yankee Con	224	6,720
Total for eleven months of 1903	5,924	177,780
Total for year of 1902	3,278	81,950

CONCENTRATE SHIPMENTS.

1903.

Name of Mill or Jig.	No. Cars.
May Day mill	2
May Day jigs	20
South Swansea jigs	1
Total for eleven months of 1903	23

1902.

Alaska jigs	2
Mammoth mill	47
May Day mill	10
May Day jigs	18
Tesora mill	42
Total for 1902	119

In this table it is figured there are thirty tons to the carload, this heing the average. In shipment of ore from tbe Tintic mines this year a number of new steel cars have been used and some of these have been loaded to their full capacity (about sixty tons). In that part of comparative table referring to year 1902 an average of twenty-five tons to the car was used. The shipments for the year 1903 are given only to November 30, and it is estimated tbat the output for the month of December will amount to 500 carloads, or 15,000 tons.

Carbon County.

Had it not beeu for the strike in the coal region of Carbon county, the year's business in Utab coal, as indicated by official figures, would have shown a considerable increase, says the Salt Lake Tribune. Taking into account the average daily output of the several mines of the Utah Fuel Co., the total tonnage raised for the first ten months of 1903 was as follows:

	Tons.
Winter Quarters	420,900
Clear Creek	494,700
Castle Gate	352,800
Sunnyside	485,100
Total	1,753,500

All of the foregoing tonnage, with the exception of the Sunnyside and part of the Castle Gate output, which was converted into coke, was marketed for rail-

way, industrial, commercial and domestic purposes. If this had been a normal year the output would have aggregated 2,105,000 tons from all the mines. The cost of producing the ten months' output of 1,753,500 tons was $1,255,000, distributed among 2093 employes, equivalent to 71.5 cents per ton. In addition to 204 coke ovens at Castle Gate and 201 at Sunnyside in operation, the company is building 100 ovens at Sunnyside, which will bring the total number up to 505 ovens. While most of the Utah coal is consumed in Utah, a considerable portion is shipped to Colorado, Nevada, California and other neighboring States. The Southern Pacific railroad is also a large consumer.

Box Elder County.

The Utah Iron & M. Co. has been incorporated at Ogden to develop and work a group of iron veins in Box Elder county by L. W. Shurtliff, P. G. Lamoreaux, T. B. Farr and F. M. Farrell.

Summit County.

The Silver King Con. mine at Park City has put in its pump on the 700-foot level, preparatory to sinkiug for the contact.

Work has been discontinued at the Steamboat mine at Park City.

The output of tho mines of Park City are ostimatod to have reached value of $5,000,000 for the year 1903.

Uinta County.

The Paritte gilsonite miue, near Fort Duchesno, is developing a 3-foot vein on the 300-foot level.

WASHINGTON.

Ferry County.

A strike of gold and copper is reported in the Bryan mine, near Orient, and ownod hy E. F. Graves ot al. of Spokane. The shoot is 14 inches wide and the ledge shows 4 feet wide. The Bryan claim adjoins the Lucky Charlie group and the Abe Lincoln claim, 4 miles north of Orient.

Stevens County.

(Special Corrospondence).—The Molybdenite property, 14 miles east of Bossburg, is under option to Spokane and New York men. The ledge is a flat vein and lies in granite, varying from a few inches to 4 feet in width. The gangue is quartz, the molybdenite being well disseminated. The ore assays 10% molyhdenum. In places where the ore has become oxidized a sulphur residue is loft, which shows the outline of the molybdenite scales. In some specimens are pieces of molyhdenite incrusted with sulphur.

Mulligan Bros. are developing the Pittsburg group on O'Toole mountain. The Pittsburg is said to carry uraninite.——A find is reported made on the Bryan group at Rockcut, showing gold and coppor values in a ledge 4 feet wide.

F. M. Cot rell, superintendent of the Little Giant mine, in Pierre Lake district, is developing the mine hy a diamond drill. Work will he iucreased.

Bossburg, Dec. 26.

T. F. Hertzell, prosident and manager of tho Jay Gould mine at Chewelah, has resumed work on the mine after a temporary suspension of two months.——B. F. Parker, maoager of the Alice G. M. Co., is putting up buildings on thó Juoo and the Echo mines, 2 miles east of Chewelah, after which dovelopment work will he started.

Whatcom County.

Work was again started last week on the Hoosier mine, in Mt. Baker district, east of Whatcom. Whon work was stopped last spring three drifts, totaling 100 feet, had been driven into Church mountaio. The work startod is a crosscut tunnel, which cuts all four ledges on the property and is 400 feet below the drifts. T. Barber is superiotendent.

FOREIGN.

AFRICA.

Transvaal.

The Transvaal Chamber of Minos at Johannesburg, under date of Dec. 10, reports:

Natives distributed to mines during November by Native Labor Association	6,307
Time-expired and other wastage	5,854
Net gain during November	363
Total number employed end of November	69,311

An allotment of 390 natives was made to the railways, otherwise there would be a net gain for Novemher of 743.

The Transvaal Chamber of Mines at Johanneshurg reports the gold output for November, 1903, of the mines which have so far restarted working amounted to 272,107 fino ounces for the Witwatersrand —heing a decrease of 3557 ounces as comparod with the previous month. Tho return for the outside districts is 7706 ounces —a decrease of 1174 ounces as compared with Octoher. The following tahle gives the output in fine ounces for the year, compared with 1902:

	1903. Rand. Ozs.	Outside. Ozs.	Total Ozs.	1902. Total Ozs.
January	192,634	6,345	199,279	70,341
February	187,977	8,536	196,513	81,105
March	208,456	9,009	217,465	104,127
April	218,900	8,971	227,871	119,589
May	224,409	9,710	234,125	138,602
June	228,167	10,153	238,320	142,780
July	242,070	9,573	251,643	149,179
August	262,569	9,349	271,918	162,750
September	267,513	8,684	276,197	170,802
October	275,664	8,880	284,544	181,440
November	272,107	7,706	279,813	187,375
December	.....	....	.....	196,023
Totals	2,580,766	96,922	2,677,688	1,705,113

The output for month of December, estimated at 273,000 ounces for the Witwatersrand and 8500 ounces for outsido camps, brings tho total for 1903 up to 2,959,188 fine ounces of gold.

AUSTRALIA.

Queensland.

The Queonsland gold output for the month of November are as follows:

Camp.	Tons Crushed.	Yield in Ounces.
Charters Towers	23,700	33,700
Croydon	4,100	6,300
Gympie	16,800	14,500
Mount Morgan	30,500	11,900
Raveuswood	2,500	4,100
Other fields	6,500	5,600
Alluvial	....	800
Totals	84,100	76,900

The total output for the year 1903 is expected to reach ahout 900,000 ounces.

Tho New Chillagoe Railway & M. Co., at Chillagoo, reports for November the smelting plant treated; Chillagoe Co., 2761 tons of copper ore and 184 tons lead ore: Mungana Co., 529 tons copper ore and 601 tons lead ore; bought, 428 tons lead ore. Total, 3290 tons of copper ore and 1213 tons of lead ore treated, producing 281 tons of copper matte and 227 tons of lead bullion, containing 145 tons copper, 227 tons lead and 21,019 ounces silver, io the following proportions: Chillagoe Co., 99 tons copper, 8 tons lead and 7465 ounces silver; Mungana Co., 42 tons copper, 101 tons lead and 6751 ounces silver; purchased ores, 118 tons lead and 6228 ounces silver. Total, 141 tons copper, 227 tons lead and 20,444 ounces silver. Balance of product apportioned to matte retreated. The lead furnace was shut down Dec. 7th for repairs for ton days. Railway receipts amounted to £4609, made up as follows: Public traffic, £2007; company's own traffic, £2602, and the working expenses amounted to £2250.

BRITISH COLUMBIA.

Bonndary District.

Diamond drilling at the Volcanic mine, on the North Fork of the Kettle river, near Phœnix, is under way. A. Mead of Marquette, Mich., is engineer for the compaoy that bonded the Volcanic.

Superintendent H. H. Shallenherger has development going ahead on the Dom Pedro claim of the group owoed by the Chicago & British Columhia M. Co., in Skylark camp, and is sinking a shaft farther up the hill than the old shaft.

Manager McVicar, of the E. P. U. and Gold Finch mines, has finished the 1000-foot gravity tramway, which will facilitate sonding out shipments of ore to the smelter at Greenwood.——This month the incline shaft on the Providence mine, which is down 183 feet, will be deepened. This mine is shipping two cars of high-grade ore per month, and has forty-two men on its payroll.

At the Elkhorn mine, adjoining the Providence mine near Midway, fourteen men are on development work and taking out high-grade ore. The balance of $5000 on the hond on this property was paid last week hy McDonald & Sutherland.

Grand Forks reports say a strike of platinum has heen made on the Riverside group, on east side of the North Fork, 1 mile above Smelter lake. Specimens have been sent East for assay.

The shipments of ore from the mines of the Boundary district for the year 1903 are roportod as follows:

	Tons.
January 1 to June 30	265,280
July	58,492
August	69,568
September	61,388
October	73,256
November	74,431
December (estimated)	78,500
Total	680,915

This is an increase of ahout 30% over the output for 1902.

Cassiar District.

The Dry Hill Hydraulic M.Co. of Whatcom, Wash., has suspended operations on its group on Lorne creek, at Lorne Creek camp, until spring. It is intended to start work again io April. There is in process of construction a wooden flume 2½ miles long, of which 4000 foot has heen completed. Included in the route surveyed for tho flume is a wall of rock which will have to be cut through for a distance of 700 feet. Machinory and pipe for the hydraulic plant is on tho ground. When the flume is in place tho system will provide 1500 inches of water. F. E. Holt is manager.

East Kootenay District.

All the new coko ovens of tbe Crow's Nest Pass Coal Co., at Michel, that aro finished (about 200 in all) have been kindled and begun to put out coke.

Montreal men have incorporatod the Imperial Coal & Coke Co., Ltd., to operato coal areas on Fording river, north of the areas owned hy the Crow's Nest Coal Co., and near Michel. The northern limits of tho areas are 40 miles from Michel, and they extend south for 30 miles. The western boundaries aro the property of the Crow's Nest Coal Co., the Canadian Pacific coal lands and 50,000 acres owned by the Dominion Government, and east by the forty-two coal locations on Elk river owned by tho Canadian Pacific Railway Co., says the Fort Steele Prospector. It is intended by the Imperial Coal & Coking Co. to start development work this month, also construction of a branch railway and the building of coke ovens.

Nelson District.

It is reportod the Dundee mine at Ymir has heon sold to C. D. Rand of New Westminster for London, Eng., parties, and $7000 paid down. The work oo tho mine consists of a shaft 250 feet, with laterals running from same. These drifts show ore carrying galena with values of $20 gold, $10 silver and 30% lead. A concentrating mill is proposed.

Slocan District.

The total shipments for the ontire Slocan district of silver-lead and zinc for the year has aggregated 13,000 tons. This is the lowest output of any year in the history of the camp, says the Rossland Miner.

Rossland District.

The shipments of ore from Rossland district mines for the year 1903 were as follows:

	Tons.
January 1 to May 31	147,870
June	36,360
July	31,360
August	36,010
September	39,651
October	38,151
November	38,576
Decemher (estimated)	38,800
Total	406,778

Vanconver Island.

G. E. Graham of Fairhaven, Wash., of the Grihbell Island M. Co., operatiog on Gribbell Island, says two shifts have been worked on the company's property since June 1, and 285 feet of tunnel have heen driven. At the beginning of the summer's work the miners sunk a shaft some distance from the ledge, which showed values, but water prevented them from continuing, so they turned to driving the tunnel to tap the ledge. The compaoy will continue operations during the winter.——Manager Mitchell of the Canadiao-American Co. of Whatcom, Wash., which has holdings on Grihholl island, says several men have heen employed on the Canadiao-American claims. The compaoy made a shipment of oro for trial to the smelter.

Yale District.

The Iron Mask mine, near Kamloops, is to be equipped with a plant to consist of a douhle-drum hoist capable of lifting a four-ton skip 600 feot por minute; a tandem Corliss condensing engine of 250 H. P., with other improvemeuts, including superheatiug of steam hetweeo high and low pressure cylinders; a ten-drill two-stage air compressor; a 300-light electric light plant; a sawmill and timher framing machinery, and two 125 H. P. steam boilers of 150 pounds working pressure. The Iron Mask has two payable veins, says the News-Advertiser, the footwall vein heing a high-grade chalcopyrite, shipments of which to the smelter gave an average of 12% copper. The hanging wall hody is lower grade, and to treat this ore and bring it up to a shipping percentage the company will huild a conceutrating plant capable of treating 200 tons per day.

BRITISH GUIANA.

The gold entered at the Custom House at Georgetown, for export, during 1903, from Jan. 1 to Nov. 17 was.

	Ozs.	dwts.	grs.		
1903	75,602	9	23	at	$1,316,909.56
1902	87,576	4	17	"	1,330,765.79
Decrease	9,973	14	18	"	$213,856.23

Diamonds sent out during same period were.

1903	8,079¾ Carats	..	Value $67,513.49
1902	10,615 "	..	" 104,303.44

CANADA.

Nova Scotia.

Halifax reports to the Provincial Mines Department say deposits of copper ore have heen found at Cheticamp, Cape Breton. One of tho oro bodies is reported measuring 100 feet wido, and carrying gold and silver values.

Yukon Territory.

The Yukon output for the past year is placed at $10,000,000 in gold.

Recorder Burwash at Whitehorse says 440 claims have been staked on the new creeks since the stampode to Bullion began. Of theso 190 are located on Bullion, 80 on Sheep and 54 on Metalline. He also says 875 claims have been recorded on Ruby, Fourth of July and the other creeks in that district, making an aggregate in Whitehorse district of 1315 locations this season.

MEXICO.

The production of silvor in Mexico for the first ten months of 1903 amounted to $60,198,094.31, as compared with $59,367,241.63 for samo period of 1902. Of gold the production of the first ton mooths was $11,697,160.25, against $8,132,383.39 for 1902. Of copper, $16,142,084.36 was mined, against $1,462,591.

Chihuahua.

The owners of the Colon mino at Terrazas report development work showing improvement in the mine. A hoist has been put in. The owners are F. McDonald, J. A. Nishan, J. D. Moramhert and Krakauer, Zork & Moye.

D. J. M. Botello is planning to start tho mill of the Parral M. Co. at Parral noxt week. It is expected other mills will be started in that camp this month.

A. C. Aiken of San Francisco, Cal., has hought sixteen pertonencias of mining ground near the Pedro Prieto estate, near Parral, the ground including the Sao Juan mine.

The Torreon smelter has bought the Los Adargas mine, near Dolores station, oo the Mexican Central, below Jiminez. The ores are silver-lead, carrying some gold.

A. Garcia, owner of the Refugio mine, noar Parral, has equipped the property with Cornish pumps. The pumps are placed in the mine and the power is a Corliss engine on the surface, operating the pumps by two cables.

R. C. Flower will start operations on the Sunset M. Co.'s mines at Maguarichic this month.

Jalisco.

La Fortuna M. Co. of New York is pushing work on its properties near Ahualulco. Its group includes the Candelaria, San Pedro Viejo and the Patrocinio, which are heing developed by means of two tunnels, with crosscuts and drifts, the total work amounting to 2300 feet. One of the tunoels is 1200 feet in length, and the other 600 feet. Ore is heing stored on the dump, but before putting up a reduction plant the company will make tests of the ores, and will further open up the ore bodios. R. Eames, Jr., consulting engineor, is directing operations.

Mexico.

A heavier electric plant will be put in at Dos Estrellas mino in El Oro camp, the same heing necessitated by recont enlargement of the mill and works, says the Enterprise.

The Guanajuato Power & Light Co. and the Mexican Light & Power Co. are pushing work on their respective power transmission lines into the El Oro-Tlalpujahua field. The fuel supply is said to he decreasing and olectric power is becoming necessary.

At El Oro 10,000 toos of ore are heing milled monthly on tho Esperanza mine. After passing from the mortar of the 120 stamps, the pulp is lifted in bucket elevators to launders aod distributed to fifteen Huntington mills which crush it to No. 50 mosh, and from these it is conveyed to separators and sized to slimes and sand, these in turn heing conveyed to their respective tanks and treated hy cyanidation, says the Mexican Invostor. Development consists of one threo-compartment shaft 1000 feet deep, one four-compartment shaft 1250 feet deep, levels, crosscuts, drifts, etc.

At the Rhenania mine at El Oro sinking tho three-compartment vertical shaft is progressing and the hoist and hoiler are being sot up, says Manager M. Doronherg.——The Maria Teresa is sinking the two-compartment vertical shaft aod at depth will crosscut for the Chihuahua and Doscubridora veins. Assays of the ore from surface outcrops are said to show $6.64 gold and 2 ounces silver to the ton. The shaft is down 100 feet, says Manager W. S. Page.

Manager O. A. Knox is increasing work on the San Ignacio group, in Zacualpan district, near El Oro, and the three-compartment shaft is down 100 feet. Ore which carries gold and silver is hoing shipped to the Hacienda del Calvario.

On the Descubridora mine at El Oro the three-compartment vertical shaft is

down 135 feet. Later crosscuts will he run to the Chihuahua and Descubridora veins. The mine is equipped with steam hoist, pump and two hoilers. J. Devereaux is manager.

Oaxaca.

La Union y Anexas M. Co., recently organized, has taken over and will develop the Union, Santa Rosa, Jacohina, Compadre and San Lucas mines, 12 miles southeast from Ocotlan, in Taviche district. The group lies on the Escuadra mountain, adjoining the Escuadra mine. Assays of ore from surface croppings are said to have given 50 ounces silver and 0.3 ounce gold per ton. Work is progressing under management of W. E. Davenport. J. W. Durst is president.

The Amorican G. M. & M. Co., at Jose de Gracia, has its 10-stamp mill in operation. —— Preliminary work on the 350 H. P. electric plant for La Natividad mine is under way.

San Luis Potosi.

The Victoria Annexas Co., on the San Pedro hranch of the Potosi & Rio Verde Railroad, is making shipments of ore to the smelters at San Luis Potosi. The company is cyaniding its dumps.

The Santa Maria de la Paz M. Co. reports work progressing on its properties in Catorce district, 6 kilometers from Matehuala. The ore runs $100 (Mexican) in gold, silver and lead per ton.

The San Sehastian mine, near San Luis Potosi, has heen sold for $100,000 gold to P. Barronechea et al. Shipments of high-grade copper-silver ore have heen made. ——The Tiro General mine is shipping low-grade ore. Additional machinery will he put in. The line of railroad planned by the National from Las Charcas station is heing huilt.

Sonora.

A half interest in La Higuera group of gold mines, 30 miles southeast of Magdalena and 6 miles from Cucurpe, consisting of five claims, comprising eighty-five pertenencias, has heen sold by the Brady-Levin Co. of Nogales, Ariz., which retains a one-half interest.

La Higuera G. M. Co. has heeu incorporated with R. Gird, R. Brady, R. C. Davis and H. Levin as officers. They will huild a 20-stamp mill in place of the 5-stamp mill in operation. Ahout 2000 feet of development work has heen done on the minos.

The cost of producing copper at the mines and smelters of the Greene Con. C, Co., at Cananea, bas increased from 6 to 6¾ cents per pound within the past year. which President W. C. Greene attrihutes to advanced prices of labor and fuel. The features of lahor cost in Mexico are the higb price of skilled lahor and the low price of unskilled lahor; hut the inefficiency of the latter largely rohs it of its cheapness.

At Cerro Prieto the Nogales C. Co., operating the Cerro Prieto mine, has its 20-stamp mill in steady operation. Manager C. N. Thomas of Nogales, Ariz., says it is proposed to increase tho capacity of tho mill so as to handle 300 tons of ore daily. —— Twelve miles northeast from Cerro Prieto, the Caliche Mountain M. Co., owned by Tener Bros. & Balch of Magdalena, is developing a gold property. There are two shafts 700 feet apart and considerahle drifting.

At Klondyke Camp, near Cerro Prieto, the Loraine M. Co., J. F. Tener manager, reports work progressing. The 10-stamp mill is running steadily, also the cyanide plant. The ore is 3½ feet in width and mills $15 per ton.

O. L. Near of the Transvaal M. Co. says that compauy will connect its mines with the railroad being extended from Cos to Nacozari hy moans of a narrow gauge road 16 miles long. Among the contemplated improvements are a 2500-foot tunnel and an air compressor plant.

Gillian & Thompson of Los Angeles, Cal., last week hought the Mejia mine, in Magdalena district. There are 100,000 tons of silver ore blocked out, averaging $26 per ton. It is an antigua property on which developmont work has been done. Furnaces will he huilt for the reduction of ore.

Zacatecas.

A. J. Smith of Los Angeles, Cal., has hought El Prodigo gold and silver mine near Chalchihuitos. Work is to start within three months from January 1, and a hoisting plant and concentrating mill aro proposed improvements.

NEW ZEALAND.

Tbe Con. Goldfields of New Zealand at Roofton, reports on Dec. 7 the reef struck in the lowest or No. 10 lovel of the Progross mine, giving assay value of 10 dwts., over an avorage thickness of 5 feet. Tho output for month of Novemher was: Progress mine crushod 4630 tons of ore, yielding bullion (including tailings cyanided £493, and sulphurets £784) to ostimated value of £8221. Exponses £3690, or 15s. 11½d. per ton. Expenditure on development not included in above expenses, £564. The Golden Fleece crushed 1137 tons of ore, yielding hullion (including tailings cyanided $271, and sulphurets £70) to estimated value of £1946. Expenses, £1282, or £1 2s. 6½d. per ton. Expenditure on development not included in ahove expenses, £461. The Wealth of Nations mine crushed 975 tons of ore, yielding hullion to estimated value of £1716. Expenses, £793, or 16s. 3½d. per ton.

The following returns show the quantity and value of gold and silver exported from the several ports of New Zealand during month of Octoher, 1903, says tho New Zealand Mines Record:

Port or District.	Quantity.	Value.
GOLD.	Oz.	£
Auckland	20,635	76,225
Nelson	207	830
Westport	.....	.....
Greymouth	7,753	31,012
Hokitika	.....	.....
Dunedin	5,527	21,397
Totals	34,112	129,464
SILVER.		
Auckland	59,907	6,177

The export of gold for first ten months amounted to:

	Oz.	£
1903	435,302	1,659,739
1902	418,457	1,608,598
Increase, ten months, 1903	16,845	51.141

During the past forty-six years there was exported from this colony:

	Oz.	VALUE.
Gold	15,572,507	£61,111,316
Silver	3,299,928	452,807
	18,872,435	£61,564,123

The gold returns of New Zealand for month of Novemher are given at 48,218 ounces of gold, of value of £184,831, as compared with 25,515 ounces of £24,539 value in November, 1902.

The Talisman Con. M. Co. reports returns for month of November: Tons of ore treated, 4350; value of hullion, £7877; cost of mining, milling, cyaniding and general expenses, £5758; other expenditure—mine development, £1456.

SIBERIA.

United States Commercial Agent R. T. Greener, at Vladivostok writes that hoside immense coal heds eastern Asia possesses underground basins of petroleum that will he developed in the near future. Oil springs are found in China, in Manchuria, in the Ussuri district, in Japan, and on Saghalien Island. The latter island not only possesses coal mines, hut also underground petroleum supplies. The oil springs near the river Nootovo, on Saghalien, extend over a considerable area. Notwithstanding the increased output of the Japanese oil industry, Japan must still import foreign oil. In 1900 Japan imported more than 60,000,000 gallons and in 1901 over 51,000,000 gallons. The export from Japan is considerahle, so that Japan promises to become a good market for the Saghalien oil. The development of the oil industry on Saghalien Island will help the river navigation on the Amur and in the Far East generally, says Greener. The Ministry of Agriculture and Imperial Properties has ordered that the 33-mile line along the southeastern coast of Lake Baikal he acknowledged as actual oil producing land. It extends from Kultchuoy to the mouth of the river Chermshan (54° north latitude), to the north from Svyatoy Noss.

TASMANIA.

The Briseis Tin Co., Melbourne office, reports for period ending Oct. 31: Black tin cleaned up, 36 tons 17 cwts. (Sept., 36 tons 12 cwts.); average total sluiceheads of water availahle from all sources 171 (Sept., 194). Rainfall during the month, 502 points (Sept., 379). Overburden removed, 38,490 cubic yards, in addition to No. 1 company, 16,398 cubic yards (Sept., 51,239); drift sluiced, 15,500 cubic yards (Sept., 15,400).

The Mount Lyell M. & R. Co., at Mount Lyell, reports from Oct. 15 to Nov. 11, inclusivo, a total of 28,655 tons of ore treated, heing 22,589 tons from the Mount Lyell mine, and 6066 tons from the North Mount Lyell mine. In addition to the above there were treated 781 tons of purchased ore and metal-hearing fluxes. The converters produced during same period 564 tons of hlister copper, containing copper, 907. tons; silver, 60,942 ounces, and gold, 1578 ounces.

Trade Publications.

"Catalogue No. 16" of the Biguall & Keeler Mfg. Co., Edwardsville, Ill., is of a quality that should inspire confidence in tbe quality of the pipe threading and cuttiug machinery, cutting-off machinery, hand emery surfacers and roller cutters that they build.

Personal.

F. J. NAGEL of Querida, Colo., is spending a few weeks in Denver.

H. SAYRE is manager of the Aspen-Bimetallic M. Co., at Aspen, Colo.

H. P. BENNETT of Virginia City, Mont., is in San Francisco, Cal.

C. W. PURINGTON has returned to Denver, Colo., from Canañea, Mexico.

W. G. EMERSON, interested in Wyoming mines, is in San Francisco, Cal.

J. H. ROBESON of Georgetown, Colo., is at the Whipsaw mine near Briggs, Ariz.

H. B. BOLAND, interested in mines noar La Cananea, Sonora, Mex., is in San Francisco, Cal.

G. N. MCDOW of Susanville, Cal., interested in Lassen county mines, is in San Francisco, Cal.

G. W. PEER of the El Oro mine, near Mayhert, Nevada county, Cal., is in San Francisco, Cal.

HUDSON H. NICHOLSON, E. M., is in the Sumpter district of eastorn Oregon on professional husiness.

W. COOPER, manager of the Capital M. & T. Co., has returned to Georgetown, Colo., from Denver, Colo.

SUPERINTENDENT MASTERS of the United States M. Co. smeltors at Bingham, Utah, is in the East.

G. W. MYERS of San Francisco, Cal., has returned from a tour of the mining counties of central California.

C. C. GROESBECK, manager of the Beartop M. Co., near Murray, Idaho, is in Toledo, Ohio, on a short visit.

R. L. FRARY of Nottawa, Mich., is assistant manager of the Goldon Wizard M. Co., operating near Sumpter, Or.

W. HENNESSEY has resigned as superintendent of the Last Chance M. Co., near Sumpter, Or., and has gone East.

J. L. BRYSON, manager of the El Oro M. Co., at Mayhert, Nevada county, Cal., is in San Francisco, Cal., on husiness.

E. A. SMITH, superintendent of the Struggler mine at Ward, Colo., returned from a trip to Denver, Colo., last week.

SUPERINTENDENT SCOTT of the New York mine on Indian creek, near Yreka, Cal., is in the East on a short husiness trip.

H. C. HOLTHOFF, vice-president of the Holthoff Machinery Co., Milwaukee, Wis., has returnod there from a trip to Donver, Colo.

O. A. ELLIS has returned to San Francisco, Cal., from Searchlight, Nev. He says 1904 will he a lively year for southern Nevada.

L. P. HAMMOND, manager of the Denver office of the Crocker-Wheeler Co., is in the East. He will return to Denver ahout Feh. 1st.

J. J. WARREN, managing director of the White Bear mine, at Rossland, B. C., returned to Toronto, Canada, last week from Rossland.

FRED. G. FARISH of Denver, Colo., has returned from La Cananea, Sonora, Mexico, and is at present examining mines near Telluride, Colo.

L. H. CARVER, of San Francisco, Cal., manager of the Mountain mine near Sierra City, Cal., has returned from a trip to Sierra county.

MANAGER G. W. HULL of the Cleopatra M. Co. returned to Jerome, Ariz., last week from a trip to London, England, on company business.

W. B. BUCKMEISTER of Boston, Mass., manager of the Amalgamated quicksilver mines, and interested in California mines, is in San Francisco, Cal.

J. A. FARWELL, for a numher of years with the Crane Co. of Chicago, is now located in Denver with the J. Geo. Leyner Engineering Works Co.

M. J. LIDSTONE has returned to San Francisco, Cal., having built a 20-stamp mill for tho Gladstone mine near French Gulch, Shasta county, Cal.

R. D. SEYMOUR, manager of the Denver, Colo., office of the Trenton Iron Works, has returned to Denver from New York and other Eastern cities.

E. R. CHILDS of San Diego, Cal., an assistant engineer of the U. S. Geological Survey, has returned to Yuma, Ariz., from a trip to San Francisco, Cal.

WILLIAM SHARWOOD, superintendent and part owner of the Soulsby mino at Soulsbyville, Tuolumne county, Cal., bas returned from a visit to Berkeloy, Cal.

J. W. BENNY, manager of the Shannon C. Co., near Clifton, Ariz., returned from a short trip to Los Angeles, Cal., and has gone to Boston, Mass., on company business.

LEONARD D. SIVYER, mining engineer of Los Angeles, Cal., has heen engaged for examinations on the mother lode, near Carters, Tuolumne county, Cal. Mr. Sivyer was professionally engaged at Globe, Ariz., in the early part of Decemher, and is recallod there for the present.

H. E. WEST, late general manager of the Pacific Northwest Mining Corporation, operating in Lihhy, Mont., has been appointed superintendent of tho Leonesa M. Co., operating gold mines in Matagalpa, Nicaragua, succeeding W. A. Wheeler. The property is owned hy G. D. Emery & Co. of Chelsea, Mass.

E. O'NEILL, associate professor of chemistry, University of California, has returned to Berkeley, Cal., after a six months' ahsence, during which he atteuded the fifth International Cougress of Chemists at Berlin, and also examined the oil fields of Baku, Russia. He also visited the oil fields of Burmah, Sumatra and Japan.

Obituary.

J. W. THOMAS of Leavenworth, Kans., miuing manager for W. P. Dunham of New York, died at Bocoyna, Mexico, Decemher 16, after a short illness.

JAMES GRIFFIN, a mining man of Silver Plume, Colo., died Dec. 22 of miners' consumption in Hamilton, Bermuda. Ho had heen a resident of Silver Plume for many years and was a successful leaser, principally on the Seven-Thirty mine. A wife and child survive him.

L. C. DUBOIS, a mining man of Salida, Colo., died at Salida Dec. 25th, of pneumonia. Deceased was thirty-five years of age; a graduate of Yale University. He took a leading part in the development of Tonopah, Nev. He was also superintendent of a mill at DeLamar, Nev., for soveral years. A widow and ono child survivo him.

W. M. GLASSON, a pioneer mining man of Socorro, N. M., died at Socorro on Dec. 20. Deceased was horn at Fort Carlon, Pa., in 1828. He served in the Mexican war in 1846, also in the civil war in the Confederate army. In 1865 he went to North Carolina, where he engaged in gold mining, and in 1879 to Leadville, Colo. He wont to Socorro, N. M., in 1881 and was engaged in mining from that time until his death. A wife and one daughter survive him.

JAMES B. RANDOL, who was intorested in a numher of California quicksilver and silver mines, died in New York City, N. Y., Dec. 23rd, of heart disease, in his sixty-eighth year. Deceased was horn at Newburgh, N. Y., and weut to California in the late sixties, where he became interested in the New Almaden quicksilver mine, of which he was later manager for twenty-five years. He was also owner of the Mirabel quicksilver mine. He was a memher of the Metropolitan, Engineers' and Lawyers' cluhs and the American Institute of Mining Engineers. He is survivod hy a widow and five children.

Commercial Paragraphs.

A. MIDDLEBROOK of Donver, Colo., manager of the Jeanesville Iron Works Co., Denver branch, has sold the Leyden Coal Co. two mine pumps, 750-foot lift.

MR. HYDE, formerly Denver manager of the Garlock Packing Co., now has charge of tho entire Western business of the company, with office at 537 Mission Street, San Francisco, Cal. The company is now fitting up its new estahlishment at Palmyra, N. Y.

To secure larger space and needed facilities the Sullivan Machinery Co. has removed its Denver, Colo., offico, to a new specially designed building at Nos. 1752-1754 Broadway, opposite the Brown Palace Hotel, where an increased stock of Sullivan air compressors, rock drills, coal mining machines, diamond drill supplies and duplicate parts will ho carried.

THE Denver office of the Trenton Iron Co., Trenton, N. J., reports the sale of a 4000-foot, fifty ton capacity per hour, aerial tramway to the Bradshaw Mountain C. M. & S. Co., at Middleton, Ariz. The Lundherg-Dorr & Wilson aerial tramway, boing erected by tho Trenton Co., is expected to he in operation by Jan. 1, 1904. The ono they huilt for tho San Juan S. & R. Co., at Silverton, Colo., is now finished and in operation.

Books Received.

"Friction and Lost Work in Machinery and Mill Work" is the title of a new volume on this interesting and important subject by Robert H. Thurston. The fact that this is the 7th edition of this valuable treatise is as complimentary a thing as could be said of it. The work treats of the theory of machinery, its action and its efficiency; nature, laws and theory of friction, lubricants, experiments on friction, etc.; the cost of lost work due to friction and recent investigations of the subject; 430 + XII pages; 77 figures; cloth, $3. John Wiley & Sons, New York; Chapman & Hall, London.

"Machine Design," by Forrest R. Jones, is just from the press, being the third edition, revised and enlarged. The book is devoted to bearings and their lubrication, spur and friction gears, belts and ropes for power transmission, screws for power transmission, screw fastenings, shafting and positive shaft couplings, friction couplings and brakes, flywheels and pulleys, and other important data on machine design and construction. It contains 426 + IX pages, with 243 figures. Price $3. John Wiley & Sons, New York. Chapman & Hall, Loudou.

"The Polar Planimeter and Its Uses in Engineering Calculations," by J. Y. Wheatley, C. E., an American authority on these instruments, is a clear and concise description of the polar planimeter and detailed explanatiou of the application of tho instrument to the solution of commonly occurring operations of engineering practice. It includes also complete tables of factors and other data for the immediate adjustment of the planimeter for these operations, thus beiug not only a treatise on the instrumont, hut also an office book for constant uso, for adjusting any sucb instrument at once for any particular problem, without furtber calculation. Largo octavo, cloth, with twelve plates, $3. Puhlished hy Keuffel & Esser Co., 127 Fulton street, New York; 303 Montgomery streot, San Francisco, Cal.

"Gold Mining and Milbng in Western Australia," hy A. G. Charleton, is the latest volume on this interesting section of the mining world. It also contains notes on the treatment of the tellurido ores of that section, with treatment costs, etc., and also a digest of practico in other regions. The work describes the sevoral mining regions of Western Australia, their history, geology and development; tho water problem, systems of mining, and the general milling practice in vogue as well as special treatment by particular processes. For the operator the book is of great value, and for the casual and non-technical reader it is one of absorbing interest. The chaptor on mining methods is illustrated, showing the sovoral systems practiced in Western Australia, and comparisons are made with other regions, both as to methods and as to cost. The book contains 648 pages, 83 figures, besides maps and tables. It is the most complote treatise yot published on the mines of Western Australia. Price $10. Spon & Chamberlain, 123 Liberty street, New York.

Latest Market Reports.

SAN FRANCISCO, December 31, 1903.

METALS.

SILVER.—Per oz., Troy: London, 27⅛d (standard ounce, 925 fino); New York, bar silver, 55⅞c, refined (1000 fine): San Francisco, 55¼c; Moxican dollars, 43@45c San Francisco, 43⅛c New York.

COPPER. — New York: Standard, $12.37½; Lake, 1 to 3 casks, $12.37½; Electrolytic, 1 to 3 casks, $12.25; Casting, 1 to 3 casks, $12.12½; San Francisco: $15.00. Mill copper plates, $17.00; bars, 18@24c. London: £56 17s 6d spot per ton.

Copper remains practically unchanged, except for a slight advance in the London market. A recent report in Boston was to the effect that the Amalgamated Co. had placed 100,000,000 pounds of copper, but the price was not stated. A better feeling prevails in the Eastern market, due to increased foreign demand.

LEAD. — New York, $4.37½; Salt Lako City, $3.50; St. Louis, $4.00; San Francisco, $4.50, carload lots; 4¢c 1000 to 4000 lbs.; pipe 6½, sheet 7, bar 5¾c; pig, $4.75. London: £11 3s 9d ₱ long ton.

SPELTER.—New York, $5.00; St. Louis, $5.10; London, £21 7s 6d ₱ ton; San Francisco, ton lots, 6¾c; 100-lb. lots, 7c.

TIN.—New York, pig, $28.50 @ 28.90; San Francisco, ton lots, 30½c; 500 lbs., 31c; 200 lbs., 31½c; less, 32c; bar tin, ₱ lb., 31½@ 35c. London, £130 7s 6d.

PLATINUM. — San Francisco, crude, $18.00 ₱ oz.; New York, ingot, $19.00 ₱ Troy oz. Platinum ware, 75 @ 82c ₱ gram.

QUICKSILVER. — New York, $46.50@ 47.00, large lots; London, £8 7s 6d; San Francisco, local, $44@44.50 ₱ flask of 76½ lbs.; Denver, $48.00. Export, $42.00@42.50.

BABBITT METAL.—San Francisco, No. 1, 10c; No. 2, 7c; No. 3, 6¼c; extra, 17½c; genuino, 31½c; Eclipse, 35c.

SOLDER. — Half-and-half, 100-lb. lots, 19.50c: San Francisco, Plumbers', 100-lb. lots, 16.50c.

ZINC.—Metallic, chemically pure, ₱ lb., 50c; dust, ₱ lb., 10c; sulphate, ₱ lb., .04c.

NICKEL.—New York, 50@60c ₱ lb.; ton lots, 40@47c.

ALUMINUM.—New York, No. 1, 99% pure ingots, 35c; No. 2, 90%, 30@34c.

LUMBER. — (Retail): Pine, ordinary sizes, $24.00@25.00; extra sizes higher; redwood, $28.00@30.00; lath, 4 feet, $4.50 @5.00; pickets, $21.00: sbingles, $2.50 for No. 1 and $2.25 for No. 2: shakes, $13.50 for split and $15.00 for sawed; rustic, $28.00 @35.00.

NAILS.—Per keg (list prices): No. 20d to 60d, Wire, $3.35; Cut, $3.55; 10d to 16d, Wire, $3.45; Cut, $3.35; 8d Wire, $3.50; Cut, $3.50; 6d and 7d, Wire, $3.60; Cut, $3.60; 4 and 5d, Wiro, $3.70; Cut, $3.70; 3d, Wiro, $3.85; Cut, $3.85; 2d, Wire, $4.10; Cut, $4.10. Special rates for carload lots.

LIME.—Santa Cruz, $1.60 country, $1.75 city ₱ bbl.

CEMENT.—Imported, $2.50@2.75 ₱ bbl.; California carload lots, $2.25 f. o. b. at works; small lots, $2.50 ₱ bbl. in sacks, 4 sacks to hbl.

STRUCTURAL MATERIALS.

IRON.—Pittsburg, Bessemer pig, $14.00 @14.35; gray forge, $12.35; San Francisco, bar, 3c ₱ lb., 3¼c in small quantities.

STEEL. — Bessemer billets, Pittshurg, $23.00@23.00; open hearth billets, $23.00 @23.00; San Francisco, bar, 7c to 12c ₱ lb.

GENERAL SUPPLIES.

ANTIMONY. — New York, Cookson's, 7¼c; Hallett's, 6¾c; San Francisco, 1000-lb. lots, 8c; 300@500-lbs., 8¼c; 100-lb. lots, 10½c.

POWDER.—F. o. b. San Francisco: No. 1, 70% nitro-glycerine, per lb., in carload lots, 15½c; less than one ton, 17½c. No. 1*, 60%, carload lots, 13½c; less than one ton, 15½c. No. 1** 50%, carload lots, 11¾c; less than one ton, 13¾c. No. 2, 40%, carload lots, 10c; less than ono ton, 12c. No. 2, 35%, carload lots, 9½c; less than one ton, 11½c. No. 2** 30%, carload lots, 9c; less than one ton, 11c. Black blasting powder in carload lots, minimum car 728 kegs, $1.50 per keg; less car lots, $2.00 per keg.

CAPS.—3x, $5.50 per 1000; 4x, $6.50; 5x $8; Lion, $9, in lots not less than 1000.

FUSE. –Triple tape, $3.60 per 1000 feet; double tape, $3.00; single tape, $2.65; Hemp, $2.10; Cement No. 2, $3.00; Cement No. 1, $2.65, in lots of 3000 feet and up.

CANDLES.—Granite 6s, 16 oz., 40s., 11½c ₱ set; 14 oz., 40s., 10c.

CHEMICALS. — Cyanide of potassium, 98%–99%, jobbing, 23@24c ₱ lb.; carloads, 23@23½c; in tins, 30c; soda ash, $2.00 ₱ 100 lbs.; hyposulphite of soda, 3@3½c per lb.; caustic soda, in drums, 3@3½c ₱ lb.; Cal. s. soda, bbls., $1.20@1.40 ₱ 100 lbs.; sks., $1.05; chlorate of potash, 12@13c; nitrate of potash, bbls., 10c; caustic potash, 10c in 40-lb. tins; roll sulphur, 2½@2¾c; powdered sulphur, 2@3c; flour sulphur, Fronch, 3¼@3½c; alum, $2.00@2.25; California refinod, 1¾@2c; sulphide of iron, 8c ₱ lb.; copper sulphate, 5¼@5¾c; chloride of lime, spot, $2.50@2.75; sulphuric acid, in carboys, 66% B, 1¾@2c ₱ lb.; nitric acid, carboys, 8c ₱ lb.

BONE ASH.—Extra No. 1, 5@6c ₱ lb. No. 1, 4@5c.

COAL. — San Francisco, coast, yard prices: Wellington, $8.00; Seattle, $6.50; Coos Bay, $5.50; Southfield, $8.00. Cargo lots, Eastern and foreign: Wallsend, $7.50; Brymbo, $7.50; Pennsylvania, hd., $14.00; Scotch, $8.00; Cumberland, $13.00; Cannel, $8.50; Welsh Anthracite, $13.00; Rock Springs, $11.50, long ton; Colorado Anthracite, $14.00. Coke, $10.50 per ton in bulk, $13.00 in sacks; Sunnyside, $11.50, long ton.

OILS.—Linseed, boiled, hbl., 45c; cs., 50c; raw, bbl., 43c; cs., 48c; Lucol oil boiled, bbl., 44c; cs., 49c; raw, bbl., 42c; cs., 47c. Korosene—Pearl, per gal., 22c; Astral, 22c; Star, 22c; Extra Star, 26c; Eocene, 25c; Elaine, 28c; Water White, in bulk, 15½c; Mineral Seal, iron bbls., 19c; wooden bbls., 21½c; cs., 25c; Mineral Sperm, cs., 26½c.; Deodorized Stove Gasoline, bulk, 17c; do., cs., 23½c; 86° Gasoliuo, hulk, 21c; do., cs., 27½c; 63° Naphtha or Benzino, deodorized, in bulk, per gal., 13c; do., in cs., 19½c; Lard Oil, E W. S., hhl., 85c; cs., 90c; Neats-foot Oil, pure, bbl., 75c; cs., 80c; Sporm, crude, 50@55c; Natural White, 70c; Bleached, do., 75c; Whale Oil, cs., 50@55c.

WHITE LEAD.—Per lb., in kegs: 500 lbs. and over at one purchase, per lb., 6½c; less than 500 lbs., por lb., 7c; in 25-lb. tin pails, ¼c ₱ lb. abovo keg price; in 1 and 5-lb tin cans, 100 lbs. per case, ¼c. per lb. ahove keg price. Dry Lead—In hbls., 1 ton and over, 6¼c; do. in kegs, 7c.

RED LEAD.—500 lbs. and over at one purchase, ₱ lb., 6¼c; less than 500 lbs., 7c.

LITHARGE.—Pure, in 25-lb. bags, 8@9c ₱ lb.

BORAX.—Concentrated, 6@7c ₱ lb; powdered, 8@10c; fused, 20@25c; crystal, 7c; calcined, 25c.

MANGANESE.—Pure, ₱ lb., 60c.

SODIUM.—Metal, ₱ lb., $1.00.

BISMUTH.—Subnitrate, ₱ lb., $1.75.

MERCURY.—Bichloride, ₱ lb., 90c.

MOLYBDENUM.—$2.00 ₱ lb.

CHROMIUM.—90% and over, ₱ lb., $1.00.

PHOSPHORUS.—American, ₱ lb., 75c.

SILVER.—Chloride, ₱ oz., 90c@$1.00; nitrate, 55c.

ALUMINUM.—No. 1., 99%, small lots, 37c ₱ lb.; 100 lbs., 35c; 1000 lbs, 34c; ton lots and over, 33c, Pittshurg. No. 2, 90%, small lots, 34c; ton lots and over, 31c, Pittsburg.

URANIUM.—Oxide, ₱ lb., $3.50.

(These prices are wholesale, f. o. b. San Francisco, unless otherwise noted.)

Notices of Recent Patents.

Among the patents recently obtained through Dewey, Strong & Co.'s SCIENTIFIC PRESS U. S. and Foreign Patent Agency, the following are worthy of special mention:

CANE DISPLAY ATTACHMENT.—No. 746,880. Dec. 15, 1903. Le Roy Robertson, Oakland, Cal. Two-thirds assigned to J. Yule and L. W. Forsting, of same place. This invention consists in the combination with a cane or staff, of an umbrella including independent upper and lower tubes, one movable relative to the other and to which the ribs and braces of the umbrella respectively are pivoted; and a third tube fitting over the ferrule end of the cane or staff and engaging said upper tube, and causing it to slide toward the lower tube to expand the umbrella, said third tube having a socket in its outer end; and means for locking the third tube in position.

DEEP WELL PUMP ATTACHMENT. — No. 747,223. Dec. 15, 1903. G. C. Richards, Oakland, Cal. This invention is especially adapted for operation in deep artesian or cased wells. It consists in a means for removably securing the pump mechanism within the well tube at any depth for operation and in a means for automatically disengaging the locking mechanism so that the pump cylinder and all attached mechanism may he withdrawn or replaced at will and means for preventing and reducing the wear of the parts, and for replacing said worn parts without disturbing the main portion of the pump.

HOISTING AND CONVEYING APPARATUS. — No. 747,113. Dec. 15, 1903. C. J. Allen, San Francisco, Cal. Often it is desired to transfer burdens from one point to another, over a short intervening space, for example the cargo of a ship which is to be removed from the hold to the wharf alongside which the vessel may be lying, or from the wharf to the ship. The ordinary cable equipments require special driving and hoisting mechanism and special tackle which render them unavailable or unsuitable in many instances where a cable conveyor, if easily rigged up, could he used to advantage. The object of this invention is to adapt an ordinary single drum hoist to operate a cableway whereby the load is hoisted and conveyed without the use of the ordinary standing cables.

MEANS FOR COILING PIPES.—No. 746,387. Dec. 8, 1903. C. L. Schalitz, San Francisco, Cal. This invention relates to improvements in means for coiling soft metal pipes of lead, copper, etc., for use as worms or condensers in stills. The object of the invention is to provide a simple method of coiling pipe rapidly and at very small expense, and by which not a mar or sign of a dent will he left in the pipe or other evidence given of the means employed.

PUMPING ENGINE.—No. 746,343. Dec. 8, 1903. G. A. Krohn, Coarse Gold, Cal. This invention relates particularly to that class of reciprocating engines having internally actuated valves and which are employed for pumping and like purposes without cranks or revoluble shafts. It consists in a novel construction of connected valves located at opposite ends of the cylinder and of independently separately actuated plungers hy which the connected valves are alternately moved. It also consists in connections hy which the plungers are alternately actuated to change the valves at the end of each reciprocation of the piston and means for exhausting the propelling medium from the plunger chambers through the main piston to the exhaust passage.

INTERCHANGEABLE CYLINDER PUMPS.—No. 746,314. Dec. 8, 1903. G. A. Krohn, Coarse Gold, Cal. This invention consists in a construction by which the interior portion of the pump within which the plunger reciprocates is made removable and interchangeable. It also consists in a novel construction of the exterior cylinder with waterways and valve chambers arranged with relation to the interchangeable plunger cylinder and other details of construction.

BED OR COUCH BOTTOM.—No. 747,176. Dec. 15, 1903. John Hoey, San Francisco, Cal. This invention relates to improvements in bed and couch bottoms of that class in which a woven wire or equivalent support for the upper mattress is attached to a framework, which framework is supported upon the bedstead. The object of the invention is to stiffen and strengthen such fabric and to maintain the edges in their proper position, and to prevent the undue depression of the bearing surface.

GOLD SAVING DEVICE.—No. 747,268. Dec. 15, 1903. S. C. Szemanski, San Francisco, Cal. This invention relates to improvements in means for treating auriferous sands and gravels. Its object is to provide a washer simple in construction and operation which, among other things, is adapted to bring the finer precious particles into intimate contact with the contained mercury baths, and which will permit of the reuse of the water.

COMBINATION LOCKS.—No. 747,116. Dec. 15, 1903. W. Almstalden, Amador City, Cal. One-half assigned to Irvin Hoxsie, of same place. This invention relates to improvements in safe and vault locks of the type known as "combination locks." Its obj ct is to provide a lock the movable parts of which are so constructed and assembled that no clue as to any one or more of the figures or letters of a combination may be conveyed to any of the senses of the person who may be trying to open the lock; in other words, to provide a lock which can not he picked or opened by experts or others not having the correct combination.

SITUATIONS WANTED.

ASSAYER AND CHEMIST DESIRES POSITION in mine or laboratory. Address V. H., this office.

A YOUNG MINING ENGINEER DESIRES POsition as Superintendent. Successful in handling men. Up to date and practical. Practiced in obtaining highest hullion output at least cost by milling, cyaniding aud concentrating. Speaks Spanish and is conversant with Mexican laws and customs. References required and given. Address "Engineer," care of Mining and Scientific Press, San Francisco, Cal.

A COMPETENT MILLMAN OF 10 YEARS' EXperience would like to take charge of a mill in any part of the country, understanding cyaniding thoroughly. Wife would like to take charge of boarding house at same place. Address W. G., care of Mining and Scientific Press.

CAPABLE BUSINESS MAN OF WIDE EXperience is open for engagement. Now holds responsible position, but desires to be permanently located with reputable mining people who can offer inducements in a solid concern. Invites confidential correspondence and investigation of character, ability, etc. Address "Effort, care Mining and Scientific Press.

EXPERIENCED SUPERINTENDENT, ENGIneer, Metallurgist; technically and liberally educated; 15 years handling men and machinery of smelters, mills and mines. See testimonials. Address Prof. Stickney, Mountain View, Cal.

EXPERIENCED MILLMAN WISHES POSItion. Address Box 202, Enterprise, Cal.

MANAGER LARGE GOLD MINING AND milling company in Arizona desires to change his location and obtain similar position with desirable company elsewhere. Best of references from present employers. Address I. C., this office.

POSITION WANTED BY NEW YORK ELECtrical engineer with Pacific Coast company. Experienced in construction work and selling. A position where he can work into the selling end preferred. References from company with which he is now connected. Address G. P., this office.

SUPERINTENDENT IS OPEN FOR POSITION to develop gold or copper properties; experienced miner; can make underground maps and models, also do the assaying; speaks Spanish; good references from past companies. Address "Develop," care this office.

WANTED—POSITION BY EXPERIENCED ASsayer and Surveyor. Thorough knowledge of bookkeeping and Spanish. S. C. H., this office.

WANTED, POSITION BY MACHINIST AND Engineer; efficient in steam, electricity and compressed air; seven years' experience at mines; good references. Address Box 54, care of Mining and Scientific Press.

WANTED—POSITION AS SUPERINTENDENT or assistant of copper mines and smelters; competent all round man, good assayer, analyst and draughtsman; can handle labor; speaks Spanish. Address "Smelter," care this office.

YOUNG MAN WITH SOME EXPERIENCE and training in chemistry, metallurgy and general engineering, wants work at mine or any place where he can get additional experience and training. Address "Espanol," care of this office.

HELP WANTED.

A GOOD OPENING IS OFFERED TO A MAN OF engineering knowledge, with a large concern manufacturing power transmitting and conveying machinery, and which desires to reach the mining industry. Address Mining and Scientific Press, 1115 Monadnock Bldg., Chicago.

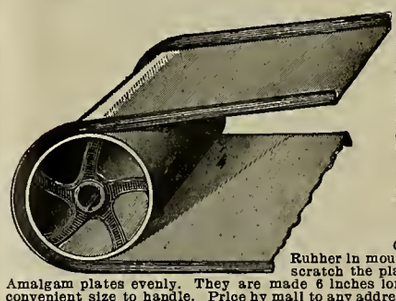
Sales Department, CHICAGO, ILL.

SPADONE'S CONCENTRATOR BELTS.

PATENTED.



This illustration shows the edge flanging outwardly as it passes over the pulley. This relieves the strain from the top and bottom of the edge by directing the strain automatically to the inside face surface of the edges. Heretofore all belts have been so constructed that when they pass over the pulleys or rolls, a direct strain comes upon the top or at the base of the edges, causing the edges to break away from the body of the belts in a very short time. *We avoid this Mechanical Defect by our Spadone Curved Edge.* Belts made to fit any machine—4, 5 and 6 feet wide. Prices and samples on application.

AMALGAM PLATE CLEANERS.

Our Amalgam Plate Cleaners are made of Pure Rubber in moulds, thus insuring a plate cleaner which will not scratch the plates and a perfect edge which will clean the Amalgam plates evenly. They are made 6 inches long, 3 inches wide and ¼ inch thick, making a convenient size to handle. Price by mail to any address, each 75 cents. Correspondence solicited.

Send us your order for Water, Air Drill, Steam, Suction and Fire HOSE, RUBBER BELTING, RUBBER PACKING and LEATHER BELTING.

New Tunnel Enterprise in Colorado.

The Mosquito range of mountains of Colorado lies to the east of Leadville and is the dividing line between Lake and Park counties.

The project of tunneling this range has been discussed for a number of years, but nothing definite has been done until a short time since, when the Leadville-Denver M. T. & T. Co. was organized, with James A. Shinn of Leadville, Colo., as president, for the purpose of driving a tunnel through Peerless mountain, a distance of 3869 feet, which will cut the crest of the mountain at a depth of 1500 feet.

This tunnel will start at the Horseshoe (see accompanying illustration), in Park county. The Horseshoe is one-half mile in width and one-half mile deep. The tunnel will terminate in the Amphitheater at the head of Empire gulch, in Lake county. One of the accompanying illustrations was taken from Peerless mountain, at the head of Empire gulch, looking toward Leadville, and shows the Sagauche range west of Leadville and the Arkansas valley, in which Leadville is located.

The tunnel, as mapped out, will pass under the sedimentary beds that contain the ore bodies of Horseshoe district. The formation is the same as that at Leadville district, consisting of porphyries, limestones, quartzites and underlying granite, cut by innumerable porphyry dikes which come up through the granite. It is believed these porpyhry dikes may be mineralized to great depth, and, as at Leadville, may be auriferous. The territory through which this tunnel will pass has produced considerable ore in the past from open cuts and shallow sbafts—none of the shafts being over 100 feet deep.

The tunnel will pass through the veins of the Peerless Maude and Stormy Petrel in Park county side, the surface workings of which are shown in the engraving on page 21.

The Horseshoe, Park Co., Colo.

But a short distance from the Peerless Maude and Stormy Petrel are located the Hilltop and Last Chance mines, in Four Mile gulch, 12 miles from Fairplay. The Last Chance ground is frozen to a depth of 450 feet, and one of their stopes is 40 to 60 feet wide, and in places 200 feet in width, without any timbering whatever. This mine is a steady producer and is now operating a 50-ton mill which was completed the past year. The mine is 12,300 feet above sea level.

For driving this tunnel it is estimated that it will cost $100,000, making it 8x8 feet, or mine size, and $235,000 if it is made 14x18 feet, or railroad size.

The power for the enterprise will probably be taken from Four Mile creek, in Park county. The power will be used for driving the tunnel, operating electric tramway, which the company expect to install, and for lighting purposes.

Arkansas Valley and Saguache Range from Peerless Mountain, Leadville in Middle Ground, Lake Co., Colo.

Mine Patent Surveys.

From different parts of the State of Colorado come anxious inquiries as to a recent ruling from that national puzzle department known as the General Land Office at Washington, D. C., which is always jolting the miner somewhere, and probably always will, till squelched by the creation of a Cabinet Department of Mines and Mining.

The recent ukase is in effect that a patented claim shall refer its lines to the lines established by the government land surveys, and affords opportunity for tricksters to annoy holders of mining patents regularly issued. What the late Justice Field termed "the ironclad potency of a United States patent to mining ground" has rarely been successfully attacked when regularly issued, and then only by due process of court. Still it must be confessed that freak rulings of clerks and subordinates can occasionally annoy and at times intimidate men engaged in honest and regular prosecution of their business. In the issue of December 12, 1903, in answer to several requests, the subject was editorially discussed. But since then considerable further correspondence from Colorado asks for more extended notice. Most of our Colorado correspondents say that as the MINING AND SCIENTIFIC PRESS is recognized as authority in those things, it is indicated that further editorial discussion herein would be of value to the mining interests of that great commonwealth and the West in general. Hence the subject is taken up in the spirit invoked by Colorado readers.

Primarily, it may be said that, in locating lines of surveys and grants, the following rules, applied in the order named, have generally been observed by our courts of last resort: First, natural monuments; second, artificial marks; third, adjacent boundaries; fourth, course and distance.

These are postulates which nobody may seriously dispute. The application of this rule is illustrated by simple diagrams on page 26.

The Government issues a patent for mining claim A. (Fig. 1.) The monuments and posts are in position at the corners, 1-2-3-4. The calls for the natural objects, tree and creek, are found as called for by the field notes; but it is disclosed that the tie call connecting corner No. 1 with the section corner of the public surveys is erroneous as to course, or both course and distance. In determining what was granted by this patent, there being a manifest disagreement between the natural and artificial monuments on the ground and the tie call, the latter must yield, as it is resorted to only in the event of uncertainty or absence of the monuments. It is essentially in this case a false call, which the courts ignore. Under this state of facts, the patentee may rest in security. The jurisdiction of the Land Department has been exhausted by the issuance of the patent. The Government can not issue a second grant for anything embraced within A, nor has it the power to recall a patent once issued and delivered, for the purpose of correcting the subsequently discovered and immaterial error in the tie call.

But this error, harmless as it may be, so far as the interest of the patentee is concerned, is productive of some confusion and difficulty in the administrative department of the Government. The surveyor-general who passes upon and plats the work of the deputy mineral surveyor, makes the record on the official map of mineral segregations in that particular section according to the field notes of the deputy. This work in the surveyor-general's office is done regardless of the position of the monuments, natural and artificial, on the ground. It is assumed that they are correctly noted in the field notes. As the departmental regulations require all surveys to be tied to the nearest recognized government section corner, the position assigned to the surveyed claim on the official map of the section is determined solely by reference to the call for course and distance from the initial monument of the survey to the section corner. In the instance illustrated, mining claim A, by reason of the error in the tie call, occupies a different position on the map from its actual position on the ground. This error naturally remains unnoticed and practically harmless until another claim in the same neighborhood is surveyed for patent. Let us assume a case which will illustrate the situation and offer a basis of discussion.

B, another mining claim (see Fig. 2, page 26), adjoins A, the side line and two corners of the two claims being common. There is no conflict on the ground. The deputy surveyor who goes into the field to ascertain this fact finds all of A's monuments, natural and artificial, as called for, but discovers the false tie call. He ties B to the same section corner by correct course and distance. His survey of B in the field creates no conflict with A. But in platting it in the surveyor-general's office, in connection with the previous survey of A, a paper conflict arises, owing to the false tie call in the survey of A, producing the result shown on Fig. 3.

This of course interferes with the Government's system of bookkeeping, and upsets the mathematical equilibrium, as all mathematical errors must necessarily do. What is to be done about it? If the principles of law enunciated at the beginning of this article are sound, A's rights are not affected, and certainly B's should not be. The only difficulty in the situation seems to rest in the method by which B is to be given what belongs to him, and at the same time keep the books straight. If it were a matter between two individuals, there would be no trouble. It is suggested that the Commissioner of the General Land Office proposes to obliterate A altogether and commence over again. As A will not be disposed to voluntarily surrender his title and institute patent proceedings de novo he is to be haled into court in an action in equity to annul his patent. But on what grounds? A's patent taken by its four corners in connection with the monuments on the ground as all courts must take it, leaves no doubt as to what the Government actually granted. There is no mistake as to the thing granted, only a false call in describing it, one which may be readily disregarded without injury to any person or thing except perhaps a disturbance of the system of bookkeeping. It is not a case where the Government granted one tract of land intending to grant another. If a controversy of this kind could be conceived as arising between individuals, the counsel who would suggest that before B could obtain title to his claim, an action in equity would have to be brought to set aside A's deed would not receive much encouragement. In its capacity as a land owner, the Government is bound by the same rules as ordinary individuals. When it becomes a suitor in the courts, it has no greater or higher privileges than its citizens. In the instance cited, which is of course simple, but none the less typical, there has been no mistake in the sense that a court of equity must be called upon to rectify it. Instruments may only be re-formed or annulled (in the absence of fraud) where the intention of the parties cannot be ascertained from the instrument itself, or in case of latent ambiguities by a resort to such extraneous facts as the law permits to be given in evidence in aid of interpretation. It must be lacking in some essential, vital quality before the powers of a court of equity can be invoked to reform or annul it.

We are not unmindful of the fact that the tie call to the public surveys is considered for administrative purposes an important one. The manual and departmental regulations require the survey to be so tied. There is nothing in the mining law itself which insists upon this requirement, but it was undoubtedly devised for the purpose of aiding the Land Department to determine by successive plattings the relative positions of the surveyed claims in the same locality, thus enabling that department to ascertain fractional areas or resultant lottings caused by the mineral segregations, and supplying other data which is useful for administrative purposes.

Yet, an error in this connecting line has never been held by the department to be fatal to the patent application, if in the notice and description taken as a whole, and considered with regard to the situation of the applicant's claim on the ground, the claim is designated with substantial accuracy. This rule has been repeatedly recognized by the department itself, and is in harmony with the legal postulates governing the courts, heretofore stated.

A common sense view of the situation would suggest that, as the error in the call tieing A to the public surveys disturbs only matters of internal administration, the proper course to be pursued would be for the department to ascertain the correct course and distance of the tie call and amend its plats, noting the fact of the original error, giving to A the position on the plat that it occupies on the ground. It would seem to be unwise to refuse to give to B what he has appropriated—inflict punishment upon him for an error for which he is in no sense responsible—and insist upon recognizing a paper conflict, with A, which does not exist on the ground.

We are not fully advised as to the extent to which the Commissioner of the General Land Office now proposes to go with regard to the manner of correcting these erroneous surveys, and the mining regions have an abundance of them. The postulates heretofore referred to were established by the courts for the simple reason that errors in surveying were not only natural, but very frequent, and that some system of rules should be devised which would accomplish substantial justice, without doing violence to the actual intention of the parties. These rules must necessarily control the courts wherever their jurisdiction is invoked in cases of this character, whether in suits brought by the United States or by private parties. If it be true, as it is claimed, that the Land Department now threatens to have suits instituted for the purpose of vacating patents which contain one or more false calls, we are quite sure the courts will decline to follow that department in cases where the property actually intended to be conveyed can be ascertained with reasonable certainty by correlating the description in the patent with the actual physical monuments on the ground, even if some of the calls for course and distance are erroneous. We feel quite certain that there is no occasion for the owner of A in the case illustrated to fear that he will ultimately lose any of his rights. If any suit is actually brought, of course he will have to defend it. The books are full of cases where the Government has brought suits to vacate patents and has been defeated. But it may never be brought. The worst troubles we have are those which never happen. If any such suit should be brought, a test case may be made, and all parties interested may join forces; and if the present attitude of the department is correctly reported by our Colorado correspondents, the best

way out of the difficulty is to encourage the bringing of such a suit. To obviate misunderstanding, it is to be noted that a suit to vacate a patent can only be brought by the federal government itself. The case cited from Colorado by most of our correspondents is an appeal from the ruling of the Land Office to the Secretary of the Interior Department.

Of course, these things are annoying and expensive, but just so long as the mining industry of this nation permits its affairs (so far as Federal connection is concerned) to be administered by inferior subordinates of an inferior government department, so long is it possible for such injustice to continue. The remedy for this and kindred hurts and hindrances is the creation of a cabinet department of mines and mining to wisely conserve and administer governmental requirements concerning the great basic industry of the nation.

The Mint Director's Annual Guess.

The Director of the United States Mint at Washington has issued what purports to be preliminary statistics on the precious metal production of the United States for 1903. The figures are so obviously incorrect for some States that a doubt is created as to the value of the estimates for others. The statement published elsewhere herein, which was issued by the Washington official, credits South Dakota with a production of $2,889,137 gold and $179,965 silver for 1903. The gold and silver mines of South Dakota are all in a limited area in the Black Hills, and never within twenty years has the output been as small as $3,000,000. The Homestake company alone produces more than $4,500,000 yearly, and this amount is being annually increased. Besides this company, the Golden Reward, Penobscot, Spearfish, Standard, Clover Leaf, Hidden Fortune, Wasp No. 1 and No. 2, and a great number of other companies output not less than $1,500,000 annually, which will make South Dakota's output exceed $6,000,000. As to the other States mentioned in the report the errors are less noticeable, but, when the year has only just closed the sum allotted to each State to represent its production is nothing closer than a guess, but the appearance of detail in the output credited to some of the States leads to the belief that the figures are the result of accurate information, when such is not the case.

CONCENTRATES.

WROUGHT-IRON pipe will probably prove satisfactory in well sinking, especially in hard ground.

****

IF limestone and some copper ore of good grade are available with the gold and silver bearing pyrite, it is probable that the ore could be worked by pyritic smelting process.

****

ONE person may locate as many lode claims as he desires to do assessment work on. They may all be on one vein or on several veins. There is no limit to the number of claims one person may take.

****

THE mineral sample from Olalla, B. C., is pyrrhotite (a sub-sulphide of iron), with a small amount of chalcopyrite (copper-iron sulphide). This ore is a frequent accompaniment of sulphide copper ore bodies. It sometimes contains nickel. This can be ascertained by having an assay made.

****

ALUM was formerly a name employed to indicate potassium-aluminum sulphate, but the term is now applied to designate a group of minerals analogous to the former, in which aluminum is replaced by iron, chromium and other metals and the potassium by other alkali metals, or by silver, ammonium or thallium.

****

THE usual grade for tracks where cars are trammed by men is 5 inches to 100 feet. On curves it should be somewhat more. It pays to keep tracks underground as clean as possible and to lay good tracks with switches which will give the least trouble. More time is lost at poor switches than will pay for making several good ones.

****

IN the American Institute of Mining Engineers one-fourth the votes cast must be in the negative to defeat a candidate for admission. In the American Society of Civil Engineers and the American Society of Mechanical Engineers only seven negative votes are necessary to defeat a candidate. In the case of the American Institute of Electrical Engineers elections to membership are not decided by the votes of present members, that matter being entirely in the hands of the board of directors of the Institute. Membership in any one of these technical associations is not a bar to admission in any other or all of them, the question being solely one of personal fitness or qualification. In all such cases professional qualification is assumed to be the controlling factor in the question of admission.

****

THE amount of water required to produce a given amount of power depends upon the head available, the kind of wheel used and also upon the volume of water obtainable; 100 inches of water under about 485 feet head will produce about 100 H. P. in a large pipe. In a small pipe the friction increases to such an extent as to reduce the power materially.

****

THE percentage of copper sulphide in ore which will pay to mine depends upon the economic conditions surrounding the mine—the size of the deposit, manner of working it, transportation, cost of fuel and the metallurgical process employed. A carbonate ore may be leached, usually, cheaper than a sulphide ore can be concentrated and smelted.

****

THE mineral specimen from the vicinity of La Paz, Peru, S. A., is bindheimite, a hydrous antimoniate of lead, with values in gold and silver. The mineral is the result of alteration of antimonial lead ore and is comparatively rare. Hardness, 5.5 to 6. It also occurs as an earthy or incrusting mineral. It occurs also at Horbauson, Germany, in Cornwall and in Arkansas.

****

THE rock specimens sent from the Colorado river region are as follows: No. 1 is garnet (the brown crystals) and epidote (the green). These minerals are sometimes found in the region of metamorphic limestone and with copper ores. No. 2 is black limestone, with gray quartz. No. 3 is brecciated quartz cemented with calcium carbonate. No. 4 is porphyry, evidently from a dike. In it occur six-sided quartz crystals. The porphyry contains much calcium carbonate.

****

THE mineral specimen from Grants Pass, Or., is marcasite (white iron pyrites), which is essentially the same as pyrite in composition, but differing somewhat in crystallization. The tabular form of the crystals is common in marcasite, also pyramidal forms, which are also present in the specimen sent. The crystals often cross at an angle of about 60°. Marcasite crystallizes in a variety of other forms—globular, stalactitic, etc. Copper is also present in small amount, which accounts for the iridescent tarnish seen on some portions of the mineral. The gangue is partly quartz and partly lime.

****

WHERE a co-owner fails to contribute his share of the assessment work on an unpatented mining claim, the Federal statute provides that the one doing the work or making the improvements may, at the expiration of the year, give such delinquent co-owner personal notice in writing, or notice by publication in the newspaper published nearest the claim, for at least once a week for ninety days, and, if at the expiration of ninety days, after such notice in writing or by publication, such delinquent co-owner should fail or refuse to contribute his proportion of the expenditure required by the statute, his interest shall become the property of his co-owners, who have made the required expenditure. The county in which the paper is printed is not material. The statute says the paper nearest the claim.

****

COPPER ORES occur in rocks of almost every description. Those of Butte, Mont., are found in granite; those of Cananea, Mex., in porphyry; those of Bisbee, Ariz., largely in limestone; those of Pennington county, S. Dak., in black slate and quartzite; those of Daulton, Cal., in chiastolite schist; those of Green Mountain, Mariposa Co., Cal., in mica schist; those of Fresno Co., Cal., in diorite; those of the Lava beds, San Bernardino Co., and the Iron Mountain, Shasta Co., Cal., in quartz porphyry; those of Amador Co. and Calaveras Co., Cal., in amphibolite schist, and, in part, in serpentine; those of Encampment, Wyo., in schist, and those of Peru in andesite. The Lake Superior copper mines are developed on beds of conglomerate and amygdaloid, and though technically ores are not so considered as related to ore deposits generally, the copper occurs almost wholly in the form of native metal.

****

THEORETICALLY nitro powders upon explosion exert their force equally in every direction from the center of the exploding mass, but as the evidence of their explosive force, when placed upon the ground, is only noticeable in a downward direction, where a hole of greater or less size is usually found. The force in an upward or horizontal direction was expended upon the air and no record of it is available. In blasting the powder will break in homogeneous rock at an angle approaching 60° to the line of the drill hole from a point near its bottom. If there are seams or floors it is more likely to break along these lines of lesser resistance. Several sticks of nitro powder were placed upon the level ground in a grassy field and exploded. A hole 2 feet in diameter and about 10 inches deep was the only result observable, except that every vestige of vegetation within a radius of about 8 feet was completely destroyed, showing that the expansive force of the explosion extended to that distance.

****

THE rock specimens from Casa Grande, Ariz., are: No. 1 is wholly made up of volcanic material (tuff), and may show lines of stratification in large masses, though none are apparent in the hand specimen. No. 2 is similar to No. 1, being also a tuff, made up of volcanic material. No. 3 is olivine basalt and No. 4 is similar, though finer in grain. No. 5 is a typical quartz porphyry, showing numerous phenocrysts of quartz and orthoclase feldspar; it seems at one time to have also contained either hornblende or mica, but the original mineral has been obliterated by weathering; the occurrence of small crystals and bunches of epidote suggest that the bisilicate was originally hornblende. No. 6 is evidently separate from No. 5 and may be a distinct dike; it is much altered and looks like feldspar porphyry; a rock of somewhat similar appearance from the Contention mine, at Tombstone, Ariz., carries gold. All of the rocks sent are either of volcanic or igneous origin, though they may occur as a portion of formation which is of sedimentary origin. The tuffs may be mistaken for sandstone.

****

CALICHE is a Spanish name, used variously to denote several kinds of mineral deposit. In South America it is applied to deposits of crude soda niter (saltpeter). In Arizona the caliche is a calcareous deposit formed beneath the surface sand or soil and in some districts extends over large areas. It is also found in some portions of southern and Lower California, in New Mexico and in the desert region of Western Australia. It generally conforms more closely to the surface contour of the ground than to any stratification of the debris that may be present. In some localities the caliche is gold bearing, the occurrence being similar to gold-bearing conglomerates. The formation of this calcareous deposit beneath the surface is supposed to be due to the precipitation of calcium carbonate from upward-flowing solutions, induced by the rapid evaporation of those arid regions. The infrequent rains leach the calcium carbonate that may be deposited in the upper layers. Calcareous travertine is deposited on the surface from calcareous springs and is different from caliche.

****

IN many modern mines electricity is used for signaling on engine planes and in shaft hoisting. It is also used therein for speaking purposes, as in the telephone, and in mines where safety lamps are used it is considered the best means of firing shots. Electricity is also largely employed to do the heavier work of lighting, hauling, pumping, machine coal cutting, rock drilling, hoisting, and driving ventilating apparatus. Electricity for speaking or signaling purposes needs the use of only a feeble current, usually produced by chemical action set up by causing the liquid chloride of ammonium to act upon two distinct metallic substances, usually copper and zinc, in connection with each other by a suitable wire circuit, or by substituting carbon for copper, which is done in the Leclanche cell, commonly used for this purpose in mines, the extent through which the electric energy may be felt depending upon the length of the connecting circuit. Shot firing is usually done by means of a small magneto electric battery, or miniature dynamo, in which case the feeble currents from the electrically excited magnets pass along the cable to the highly sensitive detonating material enclosed in the copper tube, called the detonator. Sufficient resistance is set up in the detonating material to cause a spark to pass in the high tension arrangement, or to heat a very fine strip of platinum in the low tension, either of which is sufficient to detonate the matter and explode the charge.

****

IN the construction of concrete mortar blocks in stamp mills, a constructing engineer thus describes a method of securing an even and level top to the block. The block is built of concrete of the best materials obtainable, and surfaced with a layer of sand and cement about 1 inch thick put on immediately the block is finished. The anchor bolts are "eye bolts" secured to railroad iron embedded in the concrete. These are carried to the surface of the block in iron pipes, and extend to the proper height above the surface of the block. A form, exactly the size of the bottom of the mortar, is made by bolting solidly together several 4x6 timbers. These are planed to a true surface on one side and on the opposite (upper) side a strip about 2 inches wide is dressed perfectly true with the under side. This form is provided with bolt holes at the proper places and while the surface of the concrete is still wet the form is placed in the position to be occupied by the mortar on the concrete block. The nuts are then screwed down firmly, the result being that by use of the level the form is made to press the yielding concrete to a true and absolutely horizontal plane. The form is left in this position until the cement has set hard—at least twenty-four hours, when it may be removed and the mortar placed in position when the block is dry enough, a gasket of sheet rubber being placed between the bottom of the mortar and the concrete. The main object when setting a mortar is to have it rigid, so that it will have no tendency to rock. This is of greater importance than to have the mortar set exactly level, though it is desirable to have it as nearly so as possible, but a small fraction of an inch, higher or lower at one end than the other, is unimportant. The bolt holes are filled after the mortar has been lowered so that the bolts enter the holes, either sulphur or cement being run in. This method of setting a mortar obviates the necessity of grouting or shimming up, which usually results in an unsatisfactory block which soonor or later will disintegrate.

Mining Opportunities in Alaska.

Written for the MINING AND SCIENTIFIC PRESS by JNO. D. MCGILLIVRAY.

There are no gold mining fields in the world that to-day offer better opportunities for the investment of capital, properly directed, than Alaska. Yet there is no field where capital has been, until very lately, less inclined to go. The reasons for this are uot difficult to find.

There is a misconception as to the climate and the consequent conditions that would affect mining; transport has beeu difficult, expensive and iusufficient in most districts, and the costs of supplies consequeutly high; many thousands of men, nufitted for frontier life and unacquainted with mining, have gone north during the booms, naturally failed and as naturally condemned the country on their return; the Cauadian governmeut has imposed iniquitous taxes aud framed silly miuing regnlations for the Cauadiau Yukon, there were disgraceful scandals at Nome the first two or three years, owing to the corruptness of officials; the press, particularly of the East, in its ignorance, until very lately, seldom mentioned Alaska or the Canadian Yukon except with a joke or some reference to the supposed terrors of the climate.

All along the pan-handle, and along the southern coast to the Aleutian islauds, from the shore of the Pacific back to the coast ranges, the thermometer seldom registers more than 15° F. below zero, and throughout central Alaska, along the Yukon aud its branches, where are most of the alluvial gravels, the winter climate is never as disagreeable as that of Idaho, Montana, North Dakota or Minnesota, for there are no winds aud the air is dry. The Japan current is to Alaska what the Gulf Stream is to Norway and Sweden. Norway and Sweden are, largely, more thau a degree farther north than Alaska, and yet those countries have a population of about 10,000,000 inhabitants. It should be remembered that from the first of April to the middle of August there is far more daylight, and, consequently, more heat from the sun, than there is farther south. There is no frost, except at nights, occasionally, in April and August. During May, June and July the thermometer seldom registers less than 70°, and during the day runs up to as much as 95°. The result is wonderfully lnxuriant vegetation. As there is considerable rainfall during the summer, there is water in all the small creeks. Washing with water is begnn sometimes as early as the 15th of April, but generally from the 25th to the 30th, and continued until September 20th or 30th. This gives a comparatively long seasou for hydraulicking.

The cost of transport has beeu greatly reduced in the older camps, where roads aud trails have been built. In fact, for this reason alone the cost of miuing has iu cases been rednced to one-half what it was. The Cauadian goverument has bnilt many good wagon roads on its side of the line. I have seen freight from Dawson to the mouth of El Dorado creek as high as $500 a tou, and it was during the first two years, before roads were bnilt, seldom less than $200 per ton. It is now not more than $75 per ton, owiug to the wagon roads. The most important thiug for the Federal Governmeut to consider for Alaska is the question of assisting to build roads.

There is now a very good class of judges, commissioners and other officials in Alaska. This is of particular importance where so many disputes must arise, mainly caused by ignorance of the regulations on the part of locators. The War Department has built telegraph lines to the priucipal camps and next spring will lay a cable from Juuean to Seattle. Postal facilities have been extended to all the camps both for summer and winter. The United States Geological Survey has doue excellent work, and a great deal of it, all over Alaska, and there is probably no district in the United States where this is of more value and made more use of than by the miners in the North.

In most of the new placer fields there is generally a large output during the first few years, while the richest gravel is being worked by crude methods. Then there is a falling off until capital makes use of larger and better methods, and the outpnt becomes more steady. The gravel then worked is of lower grade, bnt because the cost of workiug is so much reduced the profits are larger than were those of the earliest days. This cau well be illustrated by the Nome and Klondike districts. The output of gold as returned by the Director of the Mint for Nome is as follows:

1899	$2,400,000
1900	5,100,000
1901	4,131,686
1902	4,561,869

Returns from the Nome country for 1903 so far indicate a slight decrease.

The returns for the Kloudike country, or Cauadian Yukou, according to the same authority, has beeu:

1897	$ 2,500,000
1898	11,225,819
1899	16,254,018
1900	22,765,005
1901	17,835,745
1902	14,688,988

Peerless Maud and Stormy Petrel Mines, Doran, Park Co., Colo. (See front page.)

The returns for 1903 are not all in, but show so far betweeu $12,000,000 and $13,000,000.

In the Nome country, as well as iu the Canadiau Yukon country, a very large part of the yield of last year was from gravel that would not have paid to work at the costs and under the conditions of three or four years ago. It will be seen that the largest Nome yield was in 1900 and the largest Canadian Yukon yield in the same year. Most of the gold in each case came from very rich claims, which have been worked out. Now larger areas of gravel have been controlled by capital and considerable mouey is beiug expended on ditches to bring on water for hydraulicking, dredgers, steam shovels and other appliauces, which will enable the handling of larger quantities of gravel at greatly redneed costs. As a result, at least 100 acres of the gravels of the north will pay to work now or within a few years where 1 acre wonld pay under the costs and by the methods of a few years ago.

This is well illustrated by many of the creek and bench gravels of the Kloudike district.

El Dorado creek from its month up, over 3 miles, has practically all been worked over, mostly by the drifting method. A dredger was put in to work on Bonauza in 1901 and proved successful. The owners then purchased 17 El Dorado, which had beeu worked over altogether by drifting, for $75,000, and brought in another dredger in 1902 to work this claim. In fact, all El Dorado creek will probably be dredged. Over on Dominion, in 1898 and 1899 a few claims worked by drifting paid profits. The cost of driftiug was generally more than $8 per cubic yard. A majority of the miners on that creek in those years made little or no money, and several ran into debt. At that time only about 3 miles of the creek contained gravel that would pay to work. Nearly 20 miles of lower Dominion is now being worked and better profits are being made. So it is with a large part of Bonauza, Huuker, Sulphur, Quartz and Eureka, the main creeks of that district.

At Nome very large capital is being invested iu ditches to bring in water. The gold yield from the Seward peninsula will in future, as a consequeuce, steadily iucrease and continue for many years, for the extent of the gravel is such that all the available water cannot wash it within the next five decades.

That there are large areas of gravels of high grade iu districts in all the tributaries of the Yukon, the Kuskoquim, the Copper river, and the streams running into the Arctic ocean, has beeu well enough established. They are far greater in area thau were the alluvial gravels of California, exteuding as they do along these streams throughout a territory four times as large as California.

In order to understand that all these gravels may be worked by the ordinary methods in use elsewhere it may be well to mention some of the work that is being doue. At Nome the Wild Goose Co. is conveying water some twenty miles, the Hot Air Co., the Miocene Co. and others are spending large sums to bring on water, all to be used for washing gravel. There are a number of hydraulic elevators in operation, and dredging has been carried on with as much success as in California.

Near Rampart, on the Yukon, Stoel, Ott & Swensen begau work with a hydraulic plant on bench gravels on Hunter creek last year. A contract was lately let in San Fraucisco for hydraulic supplies to cost over $18,000 for mines on Big Minook creek owued by Pittsburg capitalists. They are to work creek gravels with hydraulic elevators aud bench gravels by the plain hydraulic method. Monroe & Lindsay have purchased supplies for two hydraulic elevators to work in Hoosier creek. The Pittsburg people's plant alone will move more gravel in a season thau has been moved in auy previous year by the hundreds of miners in the district. It is estimated that the cost of mining will be from 8 to 20 cents per cubic yard. The cost by the old methods of ground sluicing, shoveling in and drifting has been from $1.80 to $9.00 per cubic yard.

In the Birch Creek country, back of Eagle, a steam shovel has been in operation for two seasons. On the Seventy-Mile river an English company and a New York company are preparing to convey from 3000 to 5000 inches of water to large areas of bench gravels they have acquired aloug that stream. Iu the Forty-Mile district the North American Trading & Transportation Co. last summer built a ditch 15 miles long to couvey water to work with by hyhraulic elevators. In the Klondike district, on the Canadian side, several dredgers have been in operatiou, the first having beeu operated during the snmmer of 1901. An English company operating on benches on Bonanza reports that with 200 inches of water the duty of a miners' inch each 24 honrs was in one case 6½ cubic yards and in another 7½.

These facts should settle the question as to whether the climate deters the use of water to move gravel. The districts named, Nome, Rampart, Birch Creek, Seventy-Mile, Forty-Mile and the Klondike, will show what may be done all over Alaska.

In nearly every district a large proportion of the gravel may be covered with water at high pressure. On the streams along the Yukon the grades are heavy and ditches would cousequently not be long. The summer rains keep up a steady flow of water, except on the smaller streams, which run down dnring the comparatively dry months of Jnly and August. The abnndance of water and frequency of sources is a strikiug feature of the country. The gravels are generally of two classes, those in the stream beds or newer gravels and those on benches or older gravels. The former will generally be worked with hydraulic elevators or dredgers and the latter by hydraulickiug.

Method of Mixing Concrete.

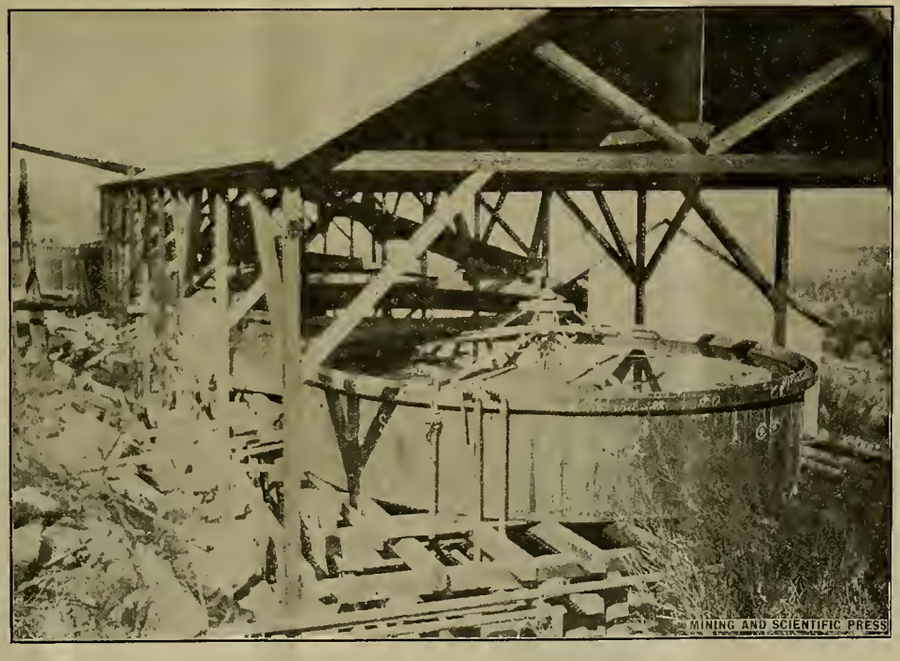
There is much variance of opinion as to the proper method of mixing concrete. The following method, from the Engineeriug News, has been employed with success. First, spread the sand, then upon the sand spread the cemeut aud mix the two thoroughly, dry. Then thoronghly drench the stones and spread them on the prepared dry mortar. Finally turn the mass over aud over, addiug water gradually until the desired degree of moisture is attained. It is of great importance that the sand and cement should be well mixed dry, separately, and should be insisted upon even when the concrete is mixed in a machine. Also, the stones should be wet separately before adding or when added. The use of bottomless boxes, as suggested by Mr. McCullough, is good. Generally, or at least very ofteu, cement barrels are used to measure the saud and stone. This method has the advantage of using the same measuring vessel for all the ingredients, and also that one or two men can be constantly at work filling barrels with sand and stones, and stauding them, handy by, for use as wanted. This makes the work go quicker. As the cement is shaken down in the barrels, it is only fair to the coutractor that the sand and stone barrels should be filled heaping. When cement is furnished in bags, four bags are commonly considered as equal to oue barrel, and the bottomless box theu comes into play, with the open question. How many cubic feet to the barrel? Usually, 3½ cubic feet will not be far out.

ALASKITE is a silicified aplite, occurriug in Alaska, aud sometimes found to be gold bearing. Aplite is au intrusive rock allied to grauite, and occurs as dikes in granite.

Types of Mill Construction.

The details of mill construction are often influenced to a considerable extent by the climatic conditions in the country where the mill is to be built. In a snowy country construction of mill buildings is necessarily more expensive than in those regions where snow is unknown. The interior of the mills may be essentially the same in both regions, but the superstructure will differ materially in design. One of the accompanying illustrations shows the appearance of a mill built in the snowy region of the southern Alaska coast, at Sea Level, the other at the Sultan mine, near Hillside, Arizona. In the former the high pitched roof shows that experience has taught that a roof at any ordinary angle would be crushed by the weight of the snow. It is not an uncommon thing to see the eaves of mine buildings in snowy regions broken down by the weight of the wet snow of late winter. This teaches that eaves must not be allowed to project beyond the side of the building farther than necessary without being supported by a brace beneath. The Arizona mill is a portion of a cyanide plant, open to the air, having only an iron roof to protect the workmen from the direct rays of the sun, and also to reduce evaporation somewhat. The cyanide tanks are of metal, and are calculated to resist shrinkage cracks which are common in the case of wooden tanks in that dry atmosphere, unless constructed with a channel near the top to contain solution or water which prevents shrinkage. These two illustrations may be said to portray the two extreme types, except those plants where no roof at all is provided, as in South Africa, and in Western Australia, which represent a still wider difference, due to climatic conditions.

The Sea Level Mill, Alaska.



Cyanide Plant Sultan Mine, Yavapai County, Arizona.

EXCELLENT TILES can be made with a mixture of Portland cement and sawdust. Nails can be driven through these tiles without causing them to crack. In a recent issue of the Thonindustrie Zeitung (Germany) the following proportions were given as suitable for the manufacture of the tiles: Damp sawdust 100 parts by weight, Portland cement 240 parts, water 48 parts. The sifted sawdust is well moistened and allowed to stand for twenty-four hours before being employed for mixing with the proportions of cement and water mentioned. The sawdust is used in a damp condition to prevent it from absorbing from the mixture the water required for the proper setting of the cement; and during the process of drying after molding, the tiles are repeatedly sprinkled with water with the same object in view. Previous attempts to make durable tiles with a mixture of sawdust and cement are said to have failed owing to the absorbent action of the sawdust.

SYSTEMS of shop cost keeping, says Cassier's Magazine, have been so much harped upon, both in papers before technical societies and in technical periodicals, that it would seem as though pretty nearly everything had been said and printed about them that could be thought of, and in very many instances the only result has been a waste of time and printer's ink. When a system of any kind requires several additional systems and a special staff to keep it going properly, it is safe to conclude that it is not what you want. It is not likely, in that event, to be a time and money-saver, and that is what the right kind of system ought to be.

To determine sulphur in pyrites oxidize with aqua regia, repeatedly evaporate with hydrochloric acid, separate the silica, precipitate iron with ammonia, precipitate sulphur from filtrate by barium chloride.

Testing Ores for Cyanide Treatment.

NUMBER II.

Written for the MINING AND SCIENTIFIC PRESS by R. STUART BROWNE.

CHEMICAL CHARACTER.—To determine acidity, four ounces of the crushed sample are placed in a glass-stoppered bottle with 250 c.c. of standard $\frac{N}{2}$ NaOH, and occasionally shaken. At the end of a couple of hours a portion of the solution is filtered off and titrated with standard acid. The amount of alkali required to neutralize one ton of dry ore is then calculated. As slacked lime is generally used for this purpose, it is best to express the acidity in terms of lime. The acidity may be due to the presence of either soluble or insoluble compounds. A distinction is often made by applying the term "soluble acidity" to that which results from compounds which may be removed by water, and latent acidity to that due to insoluble substances. The distinction is good, but not altogether of practical value. As a general rule, ore should never be subjected to a water wash in a tank wherein cyanide solutions have been. A portion of the cyanide is retained by the filter and wood, and during the process of washing dissolves out some of the values, which are lost. Where water washing is necessary, separate tanks should be provided. Owing to the difficulty of doing this, it is seldom done. If necessary, the soluble acidity may be determined by agitating four ounces of the sample with 250 c.c. of water, filtering, and then titrating a portion of the filtrate with the standard alkali. In such cases it is also well to find the amount of soluble salts present. This is done by thoroughly washing a weighed amount of the sample and reweighing after drying. The latent acidity is the difference between the soluble and total acidity.

A good many text books say that the amount of cyanide lost in treating an ore may be determined by agitating a few grams of the pulp with a standard solution of cyanide for a few minutes and then titrating some of the solution and calculating the loss. Results so obtained are of no value, for the consumption of cyanide is influenced by a great many things of which no account is taken in such a test. If a determination is made it must be done when making the final test and observing the regular working condition as regards alkalinity, time of leaching, strength of solution and ratio of weight of solution to weight of ore.

TESTING.—The most favorable case: In order to systematically determine the conditions most favorable for cyaniding an ore, some knowledge of its behavior with cyanide must be had. This is best obtained by making what I call "The test under the most favorable conditions." This is an experiment made with the ore under conditions more favorable than would be met with in practical work. If the ore does not yield a good extraction, it is evident that the ore is not a cyaniding one, and that fact is discovered at the beginning of the work instead of the end. If the extraction is satisfactory the chemist has some data to work on, and he goes ahead to develop a commercial process. The test consists in taking 250 grams of ore crushed to 100 mesh, 750 c.c. of 1% of KCy, 5 grams of an oxidizing agent, as potassium chlorate or sodium peroxide, alkali to neutralize the acidity, and agitating the whole in a bottle with compressed air for a couple of days. The conditions of the test are, of course, subject to considerable variation. If an ore will not yield to this treatment, it may be taken for granted that straight cyaniding will never give satisfactory results with it. Before proceeding, it may be best to say a few words about calculating results. I have always found it satisfactory to work with the metric system altogether, and to figure the percentage of extraction from the total quantities involved. If, for example, I am working with 500 grams of ore, the total quantity of gold and silver in the 500 grams is determined, and the same is done with the tailings at the end of the experiment. From the total amount of gold and silver before and after, the percentage of extraction is calculated. This is always checked with the solution assays. The amount of solution used is always known. By assaying it, the exact amount of gold dissolved out can be found.

Non-extraction: We will suppose that we have tested an ore under the most favorable conditions and obtained a low extraction. In silver ores the cause is probably due to the existence of the silver in complex forms not affected by cyanide. Silver in any other form than chloride requires fine grinding, strong solution, long contact and a large volume of solution. The ore will probably require a chloridizing roast before cyaniding.

With gold ores the trouble may be:

(1) Lack of time: The ore may be adapted for the treatment, but require a longer contact. Make another test with the ore crushed to 40-mesh, using straight percolation, a weaker solution and giving ten days' treatment.

(2) Coarse gold: If any is found, remove it by amalgamation and repeat the experiment.

(3) Values in sulphurets: If the preliminary ex-

amination showed high-grade sulphurets, the low extraction might be due to their presence. Try amalgamation, concentration, and then cyanide the tailiugs.

(4) Finer grinding: The ore may require finer grinding, but it is hardly possible to do this in a large plant unless the ore is high grade and a good extractiou can be had in a short time.

(5) Autimonial compounds: If the gold is held by antimony, it is not likely that the cyauide process will be suitable for the ore. Roasting may increase the extractiou.

(6) Tellurides, arsenides, etc: Ores coutainiug tellurium, arsenic, sulphur and like substances may be made to yield a high extraction by roasting. Roast some of the ore in a muffle and repeat the experiment.

(7) Solution too strong or too weak: It is hardly likely that this is the cause of the trouble.

(8) Cyanicides: If a large loss of cyanides was shown, and if the sample consisted of tailings, containing much organic matter and the products of decompositiou, repeat the experiment after giving the pulp a water wash and adding alkali.

(9) Selective actiou: In the presence of certain minerals, especially those coutaining copper, cyanide sometimes exhibits a selective action, and will attack other metals in prefereuce to gold. Try another test, usiug pulp crushed to 40-mesh, a 0.15% solution, and giving straight percolation for several days.

It must uot be supposed that these are the only causes of low extractiou. There are a great many things that influence the results, and the chemist must always devote his energies to discovering the root of the trouble. If the cause is known, it is easy to determine if a remedy is possible. A metallurgical report should always go into details explaining the cause of failure.

TESTING.—A commercial process: We will suppose that the preliminary test has shown a good extraction. It is now in order to develop a commercial process, usiug the knowledge already gained as a guide. In the case of an ore it will be necessary to determine the following things:

A. Size of screen the ore must be crushed to pass.
B. Streugth of solutiou.
C. Time of leaching.
D. Ratio of solution to ore.

In the experiments which will be made to obtain this data, it is not necessary that the work be doue ou a large scale. I consider 500 grams of ore as amply large for each experiment. The results are to be used simply for comparison, and a larger sample would not in any way enhance the value of the work.

For the tests, five glass percolators arranged in a row on a suitable stand are necessary. They should be about 14 inches long, and have an internal diameter of 2 inches. In the bottom is placed a perforated rubber cork with a glass tube, and a Hoffman clamp and rubber connection. A filter is uecessary to prevent the pulp from running through. This is made from a small circular piece of wet cambric or muslin stretched across the bottom and on top of which is placed a circular piece of filter paper. A large bottle should be placed beneath each percolator to catch the solution as it drains off. Above each percolator is placed a 2-litre aspirator with a bottom outlet. By attachiug a rubber tube and a Hoffman clamp, solution may be fed from the aspirator into the percolator at any desired speed. This arraugement of apparatus is simple and efficient. No attempt is made to precipitate the gold on zinc. One reason is that it is desirable to determine accurately the amount of gold dissolved, by means of the solution assays.

I might say here that I consider the tests made iu the laboratory ou precipitation by means of zinc shavings of no value whatever, so far as indicating the prccipitating on a large scale. The laboratory deals with pure or comparatively pure solutions, while the mill has to handle solutions that have accumulated deleterious salts from thousauds of tons of ore. What is more, the composition of the solution is continually changing. As I have said elsewhere, it is one problem to dissolve the gold and another to precipitate it. The precipitating room is the place to work out that kind of a problem, not the laboratory. The great problem is to dissolve the gold. If that can be done satisfactorily, the problem of precipitation cau generally bc solved, except where it is due to copper. In such cases it may, and it may not be.

A. To determine the screen size, samples arc taken of the ore crushed respectively to 20, 30, 40, 60 and 80 mesh. Each sample should weigh a little over 500 grams. The material should all pass the given mesh but be retained on the size following, but the 80 mesh should include everything that will pass this sieve. Each sample is now dried, thoroughly mixed on a sampling cloth and sufficient pulp taken for duplicate assays. Five hundred grams are then accurately weighed out, alkali added to ueutralize acidity, and each samplc placed iu a properly marked percolator.

Fifteen huudred cubic ccutimeters of 0.5% KCy are placed in each aspirator and allowed to flow slowly into the percolator until the ore is saturated. After a few hours percolation is started and allowed to continue for three days. The cyauide is then replaced by a measured amount of water aud each sample thoroughly washed. The samples are then dried and assayed. The percentage of extraction is then calculated and checked by the solution assays. The results are uow tabulated and an opinion formed as to the proper size for crushing. It is advisable to select the coarsest size possible cousistent with a good recovery. The fact that a fine product gives a slightly higher recovery than a coarser one should not warrant its selection. Account must be taken of the difference iu cost of crushing to various sizes. A few hours longer coutact may give the same recovery as finer crushing and shorter contact. It will sometimes happen that in the above experiments the value of the heads will vary according to the size it has been crushed to. Whcu this happeus considerable judgment must be exercised in interpreting the results.

If the 20-mesh size has proven satisfactory, other experiments should be made similar to the above with material still coarser.

If it is necessary to crush to 80 mesh, it is quite probable that the ore will have to be slimed and agitation and decantation or filter-pressing adopted. The investigations would, therefore, be carried along on this line.

If the material to be treated consists of tailings, the above tests for screen size would be omitted, for it is hardly likely that regrinding would pay.

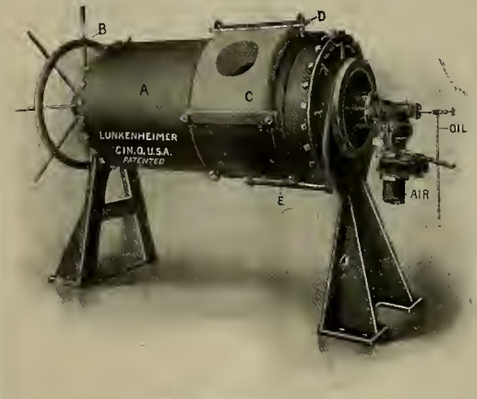
B. STRENGTH OF SOLUTION.—Having determined the most suitable crushiug size, it becomes necessary to find the proper strength of solution to use. We will suppose that we have selected 30 mesh. A little over 2500 grams of ore are crushed to this size, uo attempt beiug made to separate the finer pulp. The ore is then dried, mixed thoroughly, and a sample large euough for duplicate assays taken. Iu each percolator is now placed 500 grams of ore accurately weighed, and with the proper amount of alkali. Five solutions of 1500 c.c. each are prepared, of respectively 0.10%, 0.20%, 0.30%, 0.40% and 0.50% KCy. Each solution is placed in a marked aspirator aud permitted to run into a percolator until the charge is saturated. Percolation is then started and continued for three days. Water is then turned on, and after thorough washing, the ore is dried, sampled and assayed. From the data the solution giving the most satisfactory results is selected. If the weakest solution shows a good extraction, the experiment should be repeated, using still weaker solutions. If the strongest solutiou is necessary repeat with stronger ones. Remember that a weaker solution given a longer contact will do what a strouger one will iu a shorter one. Give preference to the weaker solution, for it means less loss in cyanide.

Generally the proper strength will be found somewhere between 0.10% and 0.50%. It is also advisable after selecting a certain solution to try one that is 0.05% weaker. Another thing to consider is the loss in cyanide, which in this scries of experiments must be calculated. Strong solutions always show a greater loss than weaker ones. If the solution selected shows a high consumption, but is otherwise satisfactory, vary the alkalinity and try a preliminary alkaline wash. If this does not stop it, try weaker solutions aud give longer contact. With some ores a large consumption is unavoidable. It then becomes a question of whether it will pay to use this process. This is a question that must be settled at headquarters after the report goes in.

(TO BE CONTINUED.)

A Metal Melting Furnace.

Herewith is illustrated the Lunkenheimer metal melting furnace, which is stated by the manufacturers to afford an efficient and economical method of melting metals, particularly brasses and bronzes. This type is the result of considerable study on this subject. The furnace consists of a cylindrical sheet-steel drum A, having cast iron heads. The interior



Metal Melting Furnace.

of the drum is lined with fire-proof tile, and there are two openings on opposite sides of the drum. Only one of these openings is in use, the other being closed by a fireclay filling. The object of haviug two openiugs is to increase the life of the linings of the furnace. It has beeu found that the furnace wears out quicker around the filling hole (which also serves as outlet for the flame), than elsewhere. An advantage claimed by the Lunkenheimer metal melting furnace is that when oue filling hole is woru out this can be closed by fireclay filling aud plate, the furnace reversed, and the other hole cut out and put in service. The oil burner is of a special type, designed to give the greatest amount of heat with a minimum consumptiou of oil. The Lunkenheimer Co. write that in their fouudry there are ten of these furnaces in use, and they are able to secure from six to seven heats per working day of ten hours from each furnace. The weight of each heat will average about 550 pounds, and the oil consumption varies from two to two and oue-half gallons of crude oil per 100 pounds of metal melted. The furnace is made and supplied by the Lunkenheimer Co., Cincinnati, Ohio.

Improvements in Cheap Copper Matting for British Columbia.

Written for the MINING AND SCIENTIFIC PRESS by RONALD C. CAMPBELL-JOHNSTON.

British Columbia is rich in immense deposits of pyrites of iron and copper. These can be classed as low-grade, carrying from 1% to 8% copper (though richer deposits also exist here under different conditions); this copper, however, is enhanced with gold and silver values to help pay dividends aud offset cost of production. The tonnage iu sight is abnormally large, but to make the mines pay engineering and metallurgical skill iu the management has to be of the highest, and every labor-saving device must be adopted.

Water power, plentiful timber, abundant fuel and railway facilities are at hand to aid cheap work.

The contour of the ground, in most cases, admits of deep adit tunuels to save pumping and hoisting, and affords an outlet to extensive open cast workings from the surface down. The engineering for mining has been brought to a high state of improvement, but the metallurgical department is not yet so much up to date as it should be.

The object of the writer is to suggest palpable improvements in the smelting, and to do this he has giveu much thought, backed by a long apprenticeship in Swansea. The objects to be attained are first to perfect a furnace into which is fed the raw, unroasted ore at the feed door, and from the tap hole is drawn blister copper of over 90% copper, dispensing with heap or mechanical roasting, and also the use of converters. The second object to be attained is a large tonuage smelted with a low loss of values in the slag, or up the stack.

With 20% to 45% sulphur in the furnace charge the most natural suggestion to be made from experience is the use of hot blast and pyritic smelting, dispensing with the necessity of carbon fuel in the furnace, and utiliziug the sulphur present, so instituting one loug oxidizing process from the top of the charge to the bath of matte at the bottom. This was successfully accomplished in 1889 by A. S. Merry at Sudbury, Ontario.

The cost of heating the blast in "U" pipes in a stove is offset by the less time consumed in the furnace to do the same thing, and the more regular running of the fusions without chilled sows.

If 2100° F. is the temperature kept in the tuyere zone in the furnace, then heating the blast to 800° F. and more in the stove, goes a long way to save time, and allows a larger tonnage to pass through. The increased size of the tuyere pipes and the use of non-radiating lining used on aceount of expanded hot air, so as to still feed the same amount of oxygeu, these are only primary costs, soon paid for.

By having a hot blast, in all smelting, entering the tuyeres, the heat is kept more normal, cold snouts are more easily avoided, a more homogeneous slag forms, and a more thorough oxidization of the whole mass procured, so the use of less flux obtained and a larger tonnage smelted.

We must, however, before looking to our smelting, see to our sampling and feeding, and try to save labor costs here. If the smelter is using ore from its own mine, aud may be only buys from one or two more to flux, then automatic sampling and automatic feeding can be installed. There are many good automatic samplers already devised, and by further improvements for local conditions, can be erected. The railway, therefore, discharges through bottom dumping steel cars its weighed burden in the storage bins. From here the ore passes automatically through the sampler and is bedded into bins systematically built near the furnace feed doors. A regular and well mixed feed into the bosh of a furnace is preferable, instead of dumping a ton or more at once from a car to chill the molten mass, having meu with shovels to mix and fill this car, and a mechanical feeder can be easily devised to keep the height of charge normal, a point so necessary in a stamp mill. Take au ordinary rotating cylinder with projecting shelves fastened on the inside lengthwise to turn over aud mix the ore; build this on an incline to discharge on to an

inclined iron plate protruding into the feed door, this plate having several ribs cast on it radiating from the discharge of the mixer to the full width of the feeding door, like extending fingers on a hand, so that the whole length of furnace is fed evenly. From the bins containing the ores and fluxes individual belt conveyors bring the ores and flux and deposit them in a hopper feeding the mixer. The gates to the bins are cast with cogwheels so that they can be opened to any size and will stay there. The lip to the bins moves back and forward into a sleeve, or rotates, as a circle, in the floor of the bin, and as a straight motion is worked by an eccentric, obviating a man barring the ore as it sticks. The feed to the mixer is regulated by enlarging and diminishing the opening of the gates, and the proportion of fluxes added is obtained by making the different gate openings correspond with the proportions of the charge mixture.

With this feeder installed for a furnace taking only a few kinds of ore, all labor costs are avoided except the one man on each shift to watch the feeding arrangements for two furnaces, and see that they work steadily.

In the construction of the furnace shaft to save fires from being carried off, the bosh well enlarged on all sides, should be carried high past the feed door so that the heated air from the tuyeres, when it has left the fusion zone, may expand and create less draught, as the enlargement of a flume slackens the current of water.

As we mentioned before, with the hot blast and pyritic smelting the process is one long oxidization from feed door to discharge of slag, so that the more blast carrying oxygen that is fed, the more oxidization takes place, the less sulphur and iron deteriorate the percentage of copper in the matte, and instead the sulphur passes off as sulphurous gas, and the iron combines as oxide with the oxides of silicon calcium, alumnium, etc., that make the slags. Forcing a strong blast into the furnace adds probably 50% to to the duty of the furnace and brings down the cost per ton, but by driving the slag out of the furnace rapidly, leaves insufficient time for the specific gravity of the matte to come into play when using an inside hearth instead of a forehearth, and so creates foul slags and a loss of values.

Also, the draught into the dust chamber and up the stack is increased and values, as dust, have too little opportunity to settle.

In smelting a large tonnage it is only a short time before the slag dump near at hand is filled up, and a slag railway has to be installed. This brings into use settlers of from 40 to 60 cubic feet contents.

The forehearth is used as a settler, but soon becomes half chilled and does not do its duty thoroughly, being also overcrowded in its work. These large slag pots will collect a skin of matte on their sides as they cool, and hold a large deposit of metal at the small end that sinks in the cooling. By having detachable pockets to retain this deposit when the pot is dumped, and by having the tilting device under control to pour slowly and gradually, and also sufficient pots in use to cool off, then the truant matte can be saved and resmelted, reducing to a minimum the loss of values in the slags.

How will we insure that the dust will not escape? The best condenser known to the writer is the "Bartlett," in which the fumes from the lead furnace are drawn by an exhaust into long flannel bags. The gaseous fumes alone escape through the material, leaving the solid lead oxides and carbon on the inside of the bags.

By shutting off the entrance of hot air, this leaves the air in the bags to cool and contract, the bags to collapse laterally and precipitate their contents into hoppers at the bottom. Any cooling and so contraction of air in the dust chambers will cause a precipitation of the dust. Alfred Senior Merry (vide "Interstellar Æther") was the first to prove that electricity and heat (thermine) were elements, as oxygen, etc.; that they have a powerful attraction for one another, in fact, always happening in some proportional combination, and as electro-thermine are drawn from the sun. Superabundance of electrity is cold, of thermine is heat. The rarefied air of mountain tops makes them snow clad, as the electro-thermine at that point has not been split up by the full weight and attraction of the earth. An electric discharge, as lightning, combines with and neutralizes the heat of the air on a summer's day, and makes the atmosphere cool.

Sir Oliver Lodge has applied electric discharges to dissipate artificial fogs. Now electric discharges in our condensing chambers will combine with and lower the heat, contract the air and cause precipitation of the dust. These fines can be deposited alternately in parallel dust chambers, one in use at a time, each with an asbestos loosely woven curtain at the far end and the dust automatically drawn by traveling plows.

Till now we have reviewed only the best practices existing for copper matting, proposing how to get clean slags of homogeneous consistency, to obtain a high duty for our furnaces, and to save outgoing values, to dispense with fuel in the furnace, to have an oxidizing field instead of a carbon or reducing field, to save labor in sampling and feeding, and dispense with previous roasting outside of the smelting furnace.

Next we have to discuss the ambition of tapping only blister copper instead of matte, and so doing without converters. To do this no new chemical reactions have to be discovered, but only oxidization has to be carried further than at present and made to come in contact more thoroughly with the molten mass.

The writer has designed a furnace he has called the "Campbell-Johnston" furnace to attain this object. He does not propose to patent it and charge a royalty for its use, but to throw open the invention for general adoption and for improvement by all metallurgists who see where an advance can be made. The only novelties in its construction are a second lower tier of tuyeres below the upper ones, and also a systematic deflection of all the tuyeres to create a more perfect oxidization from motion in slags, as in a wave with its backward undertow. As the wind plays on a sail at a tangent and forces the boat forward on its original course, so by deflecting the tuyere apertures to say 45° out of their present straight impingement, so a motion in the slags can be obtained in the fusion zone; starting from the slag launder with its straight pointing tuyeres above, then passing the upper tier of nozzles deflected away from the slag launder till it meets the downward deflected nozzles at the back end, and is taken forward again by the lower tier of nozzles deflected the opposite way to the upper ones, to rise and discharge at the launder.

This motion to concentrate the metal from the slag gives ample opportunity for the action of specific gravity, and constantly offers a fresh surface in the molten mass for thorough oxidization; the lower tier of tuyeres continues to play on the molten matte in the inside hearth, oxidizes the iron and encourages it to combine with the slag and pass away, leaving metallic copper, which metal, with the precious ones, has less affinity for oxygen than the other bases smelted.

The blister is tapped as usual into a casserole to be raised and tilted by hydraulic power to fill the anode moulds resting on trucks on rails, and is then ready for electrolytic refining. Two men at each shift are only required to attend to the tap holes and pouring for two furnaces.

By perfecting these suggested improvements in copper matting, only first metal as blister from raw ore, and subsequent refining, comprise the required processes of treatment for copper, and the first metal only calls for as actual labor on the furnace the use of three men to two furnaces on each shift, or nine men to smelt 700 tons of ore, and may be 800 tons, in the three eight-hour shifts. The quota of costs for management, assay office, engine driver for stove, boilers and engines, slag railway, sampling and general contingencies as coal for stove, oil, etc., all must be added, but the writer is confident that in the Boundary district of British Columbia $1 for smelting one ton into first metal will amply cover all costs, even depreciation of plant.

Gold Deposits of New Zealand.*

NUMBER II.

Written by ALEXANDER MCKAY.

In the course of three years subsequent to the first discovery of gold at Gabriel's Gully there was scarcely a gully or a mountain ridge from west of Lake Wakatipu to Oamaru that had not been prospected; and the attention of miners was not wholly directed to the finding of alluvial gold, since several reefs were being prospected in 1863. The results were unsatisfactory till the discovery of the reefs in the Carrick Range, several of which gave payable returns so long as the workings were confined to the oxidized portions above water level, below which the reefs were strongly mineralized, and did not pay to work.

More recent discoveries at Bendigo Gully, in the Arrow and Shotover valleys, and on the west slope of the Richardson mountains, though at times giving promise of good returns, have failed to realize what was hoped of them. On Highlay Hill, at Macrae's, and on the Nenthorn field successful working of the reefs has, except in some solitary instances, not been accomplished. Nor has better success attended reef-working in the southern parts over the West Taieri and Tuapeka Goldfields; and after forty years of such experience it may be asked, are reefs in Otago the primal source of the alluvial gold in the country?

The miner of the early days of the Otago Goldfields declared that quartz was "the mother of gold," and nothing could persuade him that it could have a different source; but it now appears that of necessity we must look to a different source.

The abundance of quartz grit scattered as patches over areas of considerable extent throughout the interior and northeastern parts of Otago does, indeed, account for the gold as a secondary deposit; but these must have had their source from somewhere, and an enormous denudation of the caps and upper parts of the reefs would be required to supply not merely the gold, but the quartz also. The reefs and their auriferous contents alike seem insufficient to produce the results that now appear, and it must be asserted of the quartz grits at least that the greater part of what they once were has disappeared in the course of ages by the ordinary process of denudation. At one time these quartz grits seem to have been an almost continuous deposit over all the low grounds and middle heights throughout Otago and Southland, and to have occupied a considerable area of southern Canterbury as well. Subsequent to the close of the Cretaceous period, movements of the land took place, by which portions of the grit formation were elevated to positions 4000 feet to 5000 feet above the sea, and at the same time other parts were deeply involved along lines of fault at unequal elevations, thus exposing in the one case the uplifted area to rapid denudation, and in the other case the upturned edges of the involved part to the same influence. In this manner great destruction of the quartz grits took place, and it is a matter for marvel that so much of them has been preserved to the present time.

Considering the comparative paucity of reef quartz over the whole of Otago and Southland, it is evident that reefs of quartz could not have supplied such a great formation of residual grits, even granting that an enormous denudation, far greater than what is usually supposed, did take place.

The lower schist formation of central and northern Otago is strongly foliated with laminæ of quartz, which, though resembling, can in no sense be regarded as vein quartz, and this is evidently the source whence has been derived the great bulk of the quartz grits at the base of the coal-bearing formation; and as these quartz foliæ are known to carry gold—e. g., at Skipper's Creek, on the Shotover, at Green's Reef, near Ophir, and at other places—such quartz foliæ must be regarded as the principal source of the alluvial gold of Otago.

While much gold has been obtained from the quartz drifts, the larger pieces of quartz in the drifts, varying from 2 inches to 5 inches in diameter, do not contain gold, numberless trials having failed to show its presence. This has been regarded as showing that the country quartz does not contain gold, and could not have yielded the alluvial and cement gold of the quartz drifts. However, it has been shown that the denuded parts of existing reefs were as unlikely as a source of the twenty-three to twenty-four million pounds worth of gold that has been obtained from the goldfields of Otago; and it is an undoubted fact that, whether in the solid parts of the quartz foliæ or no, gold is found in association therewith, and, as is often the case in connection with vein quartz, the easing and friable margins often contain gold, while the solid quartz of the middle part does not. So, also, this may be characteristic of the country quartz occurring as foliæ in the mica-schist. Other sources of gold may be suggested, such as bodies of iron sulphide or of oxide of iron (hematite); but aggregated bodies of these ores are comparatively rare, and the character of the gold in Otago is generally against the assumption. Other sulphide ores, such as copper or antimony, may be suggested, but these also are not likely, on investigation, to prove satisfactory.

The gold of Otago must therefore be regarded as mainly having origin in the schists, and in near association with the quartz foliæ that characterize the middle and lower divisions of the schists, and is but little due to the quartz reefs occurring in the same rocks, as at but few places are the foliated schists rich enough to pay for working.

GOLDFIELDS OF THE MARLBOROUGH DISTRICT.—These have characteristics in common. The southeastern portion of the area is formed of mica-schist, foliated with quartz at many places. These rocks so much resemble the foliated schists of Otago and South Westland that they may fairly be considered in age and the period of their metamorphism as identical. Reefs of vein quartz are common, but few of them seem to be rich enough in gold to pay for working; and in the case of the Mahakipawa field the auriferous reefs bear no proportion to the amount of alluvial gold that has been obtained. Of the Wakamariua field the same may be stated; nor can anything different be said of the whole of the gold-bearing area of the Marlborough district.

The Marlborough goldfields are bounded on the north, south and west by non-productive areas, over which the rocks are not gold-bearing, and towards the northeast pass under the waters of Cook strait; and they have not received alluvia from other gold-bearing sources, so that the problem of the source of the alluvial gold is by no means as complicated as is the case with the goldfields of Central Otago. Nor has the gold-bearing area been subjected to an equal degree of denudation. So that it would seem that we must consider the quartz foliæ of the metamorphic schists as in great part the probable source of the gold over the Mahakipawa field, and the quartzite already mentioned as its probable source on the Wakamarina field.

GOLDFIELDS OF SOUTH WESTLAND.—There can be little doubt that reefs of auriferous quartz occur on the western slopes of the Southern Alps. The strong probability of this is indicated by the occurrence of coarse and specimen gold in the rivers of the district south of Okarito; but, since as yet no reefs are being worked, no comparisons can be instituted.

(TO BE CONTINUED.)

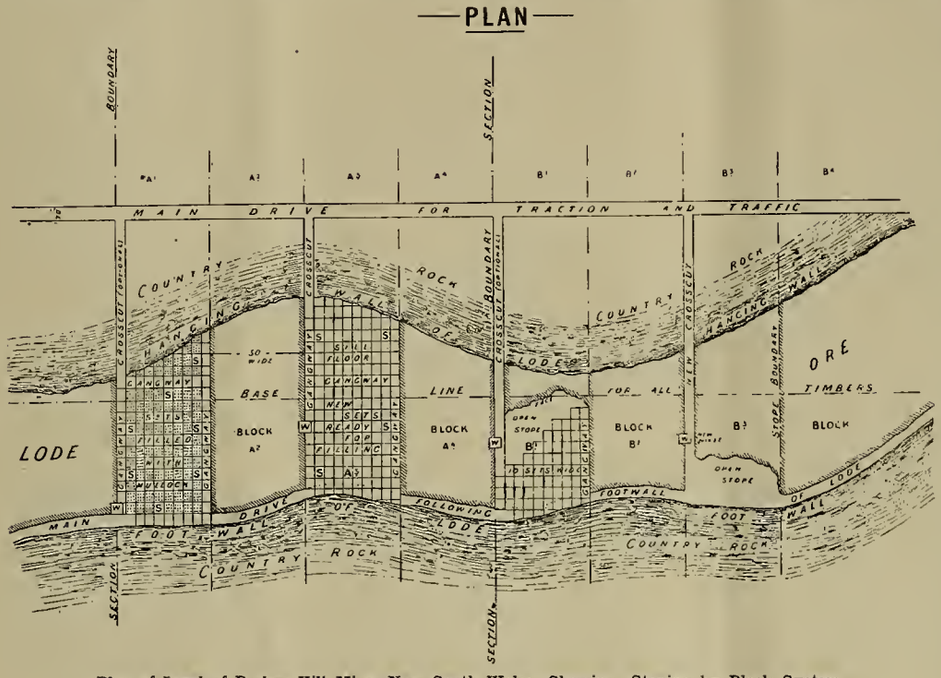
*Abstract Report of Government Geologist.

Development and Operation of a Mine.

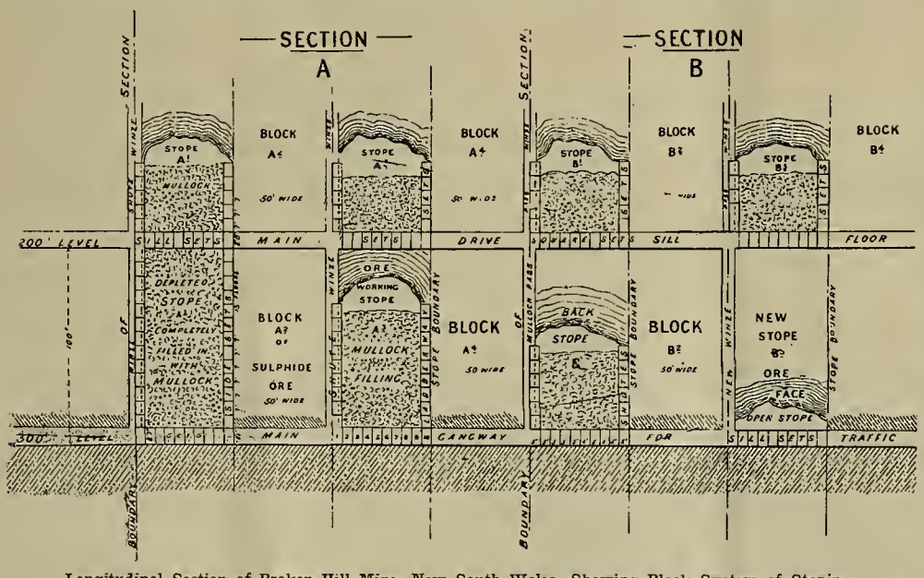
NUMBER III.

Written for the MINING AND SCIENTIFIC PRESS by W. H. STORMS.

In the former chapters of this article, the subject was treated from a broad and general standpoint, with ideal illustrations. It has beeu the desire and aim to point out the advisability of working a miue iu such a manner that disastrous results are not likely to follow the method of mining. It has also been shown that it is desirable, and even necessary, to fill the stopes with waste, and this filling should be taken wherever possible from the "dead work" of the mine, or from the surface wherever practicable. Where this cauuot be done, filling must be obtained from the walls of the vein. It is preferable to take it wherever possible from surface excavations, for



Plan of Level of Broken Hill Mine, New South Wales, Showing Stoping by Block System.



Longitudinal Section of Broken Hill Mine, New South Wales, Showing Block System of Stoping.

the reason that miuing cau be usually carried on ou the surface cheaper thau uudergrouud. It is not necessary that such excavatiou be adjacent to the vein, as the dip of the vciu or surface coutour may make it advisable to obtaiu filling elsewhere, with separate rock shafts for handling the waste, to be delivered at the various levels by crosscuts, or otherwise.

The geueral method of mining and filliug described in the last paper may be applied in a variety of ways—but to insure safety and the complete removal of all the ore with safety and with no disastrous caves, sucb as usually follow the excavation of large stopes, where filling is not resorted to—it is suggested that the stopiug be carried on by the block system in a manner similar to that followed at the Broken Hill mines of New South Wales, or at the Homestake in South Dakota. The method employed at Broken Hill is illustrated in the accompanying sketches. The mine is divided into blocks, extending 40 to 60 feet along the strike of the vein, as showu. The only material difference betweeu the Brokeu Hill system and that at the Homestake is that at the former the square sets are carried up at the ends of the stope only, the intervening space being filled with waste, while at the Homestake the square set system is carried throughout the full width and length of the stope and as close to the back as practicable, and filling introduced contemporaneously. In the early days of the Homestake development, extensive caves occurred in thc Palmetto, Highland, Goldeu Terra, De Smet and Caledonia mines of the group. All of these stopes were carefully and completely timbered with the square set, but uo filliug was run in and the caves resulted as a uatural consequence.

Within the current week a news dispatch from Pearce, Arizona, reports the Commonwealth mine as about to cave, owing to neglect to fill the stopes. This mine has proven very profitable the past few years, and extraction has been rapid and results have been rcported satisfactory, but now all the workmen have been withdrawn from the mine owing to the threatened cave, which, it is evident, is about to occur, if it has not taken place already.

To recover a caved stope, particularly a large one, is often a difficult, expensive and sometimes a dangerous operation. Such a catastrophe may be avoided by properly arrauging the detail of development and employing foresight.

In workiug by the block system of stoping, which is the only way in which large ore bodies can be entirely removed without incurring great risk, it will be necessary to place sills on the floors of each level, extending from foot to hanging wall. These sills are in sections and should reach the length of at least two sets (three sets are better), to make connection between the levels possible when removing the last slice of ore in the back of a stope beneath a level already stoped out. This can bc accomplished, if the excavation at the point of connection be not made too large. It is important that heavy lagging be laid ou the sills to keep the filling from running into the excavation below, wheu connection is made. If there is a space between the lagging and the rock floor of the level when it is laid, it is well to fill this space with broken ore, then, wheu connecting the level with the stope below, no waste need be mixed with the ore broken at that time, and the lagging has been prevented from breakiug by reason of the great weight of filling above it.

The first step in opening a new level is to run a drift along one wall and from it extend crosscuts from wall to wall of the vein. These may be driven in the center of the blocks, or a crosscut may be driven on either side of a block, as shown in the ground plan in the accompanying illustration. When the entire length of the block has been cut one set high—longitudinally of the vein aud to a width of one and one-half to two sets—the placing of timbers may be commenced if the character of the ground demands it, otherwise a heading may be driven the full leugth of the block as far as is safe without timbering. Where this can be done crosscutting is unnecessary, aud a line of sets may be left open to afford gangway at each end of the block.

If the mine is worked through a shaft sunk at some distance from the vein, then it is well to have a lateral drift outside the vein at each level, from which the crosscuts may be run to and across the vein. These lateral drifts are placed on the same side of the vein as the shaft at each particular level. Crosscuts from these lateral drifts may be run for every second or every fourth section; and, where the distance to the vein is not too great, the crosscut at each alternate block is advisable, as it will facilitate both transportation of the ore and ventilation. Tbe winze (or raise) through which filling is sent into the stopes should be made directly opposite the center of each block, thus affording the most complete and ecouomical means of filling by gravity. The stoping should be commenced next the hanging wall, instead of next the foot wall, as shown in the accompanying plan of work. This was illustratcd iu paper No. 2. As the stope progresses upward the passes for filling may be utilized for lowering timbers to the floor, where they are required from the level above. The ends of the stopc must be lined with heavy lagging as the filliug comes in. Unless this be done, when the adjoining block is stoped the filling in the old stope will run into the new and become a source of much trouble aud expensc. It may be possible to recover more or less timber from time to time, but ordinarily but littlc of the lagging can be removed to advantage. As the stoping progresses upward the ore broken is sent down the mill holes at the ends of the stope, and if the distance be too great, a line of mill holes cau be carried up in the center of the stope. This in a stope 60 feet long (parallel with the walls) where caps set 5 fect apart would reduce the maximum shoveling distance to about 12 or 13 feet. Where the only mill holes are at the euds of a block 60 feet long, too much sboveling of the ore is necessary, not one-half of it being sent below with a single shoveling. This appears to justify the center line of mill holes. These may be made either vertical or inclined as desired. The vertical hole requires the least expense for timber, while the inclined holes may be fewer in number. Iu some mines the work of stoping out a level is so long delayed that in the presence of a humid, hot atmosphere the timbers rot out before the work is accomplished. This occurs where the stopes are made very large and where frequent (and ultimately costly) delays occur because of caving or other trouble. The block system, if properly practiced, will obviate any such difficulty. Where a vein is very wide—more than 150 fcet—a system of prompt and economical distribution of filliug is necessary. This can be best accomplished by the use of cars, when gravity can no longer be economically utilized. The tracks and foot boards cau be removed from place to place as often as required.

The method of running up a single line of sets at each end of a stope, as in Broken Hill, illustrated in the accompanyiug sketch, can only be safely practiced where the ground stauds well. Easy, or caving ground had better be timbered throughout. Doors or aprous can be arranged on each level to send the filling into an adjoining stope, or allow it to continue to a lower level. There arc many details to bc worked out, which will differ more or less in different mines, but the general plau has been made sufficiently clear to make application of the ideas. The excavatiou of a large cut on the surface due to removal of both ore and waste will, of course, form a catchment basin of possibly several thousand square feet, all depending on the extent of operations, but the manager must judge for himself whether ordinary climatic conditions of the region prohibit the employment of the open-cut system of filling. Even though a large volume of water be admitted to the mine owing to occasional heavy rainfall, it is more than probable that by providing abundant bailing capacity it would be cheaper to bail the mine of this additional surface water occasionally than to employ constantly a more expensive method of mining.

The Land Office and Mine Patents.

The Land Department at Washington has created unusual interest in mining patents by promulgating a rule that patents for mining ground shall conform to the descriptions in the patent application, regardless of the position of the location on the ground as determined by the monuments. In Colorado, particularly, where this new order has been applied, it has created trouble and caused a feeling of insecurity. Concerning the whole matter, the same condition found in Colorado exists in every other State and Territory of the mining regions of the West; but there is no reason for alarm where the original position of the monuments can be determined. Regarding the whole question, in general, the situation may be illustrated by the following diagrams:

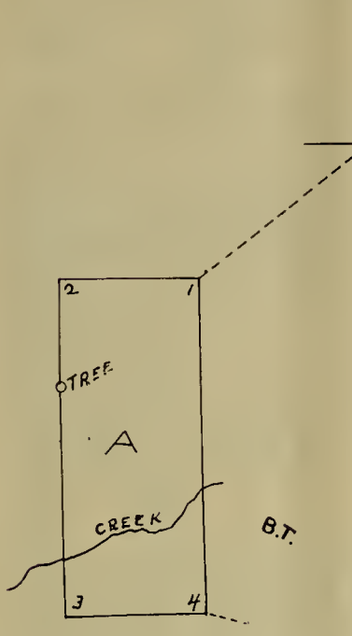


FIG. 1.

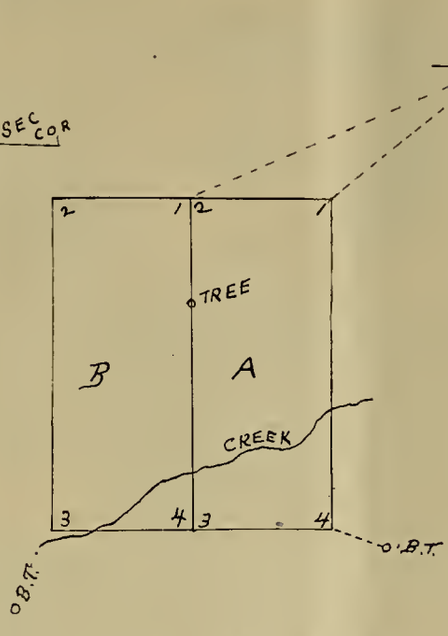

FIG. 2.

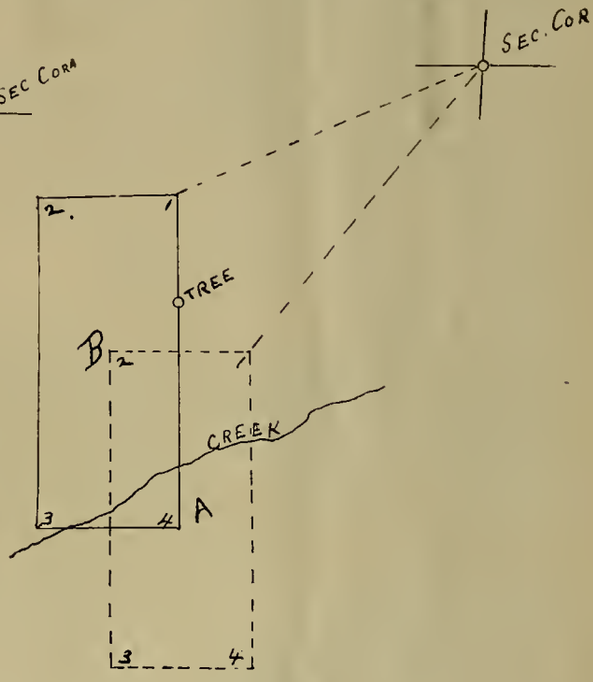

FIG. 3.

An application for patent was made for a lode claim occupying the position of B on Figs. 2 and 3. There was a "paper conflict" with a claim occupying the position on the ground, as shown on Fig. 2, but on paper, as shown on Fig. 3. The Commissioner of the General Land Office, it would seem, insists upon making an actual conflict out of the paper one, and refuses to patent that part of B which conflicts with A on paper. In making this ruling, the commissioner has said that the only way out of the dilemma is to have A's patent vacated and the claim resurveyed and readvertised.

A, the prior Colorado patentee, may feel no anxiety until he is actually attacked. Every mine owner everywhere is liable to threats of this character and others, and life would be extremely burdensome if one had to treat each threat as a serious menace. It is a questionable feature of our laws that any irresponsible person may at any time cause an innocent party annoyance and expense by instituting legal proceedings against him without any just grounds for so doing.

This whole matter is authoritatively discussed on the editorial page of this issue, it being deemed of sufficient importance to warrant such extended notice.

THE precipitation of sulphuric acid as strontium sulphate in alcoholic solution is stated to give accurate results, says the American Manufacturer. The liquid (corresponding to about 0.5 gram of sulphuric acid) in bulk about 50 c.c., is acidified with hydrochloric acid, heated to boiling, and precipitated by 15 c.c. of a 10% alcoholic solution of strontium chloride; 100 c.c. of alcohol are added, the liquid stirred and set aside till cold. It is filtered and the precipitate washed three times by decantation with 100 c.c. of alcohol, then brought on the filter and washed with alcohol till free from chlorine. It is dried, the filter incinerated with the precipitate and the whole ignited. In presence of iron, the slightly acidified solution is precipitated as above, 120 c.c. alcohol added, the whole digested at a gentle heat for an hour, allowed to cool, and the liquid poured off. The precipitate is warmed with two c.c. of hydrochloric acid (two of acid to one of water) and fifty c.c. of alcohol, the liquid filtered after cooling, then the precipitate washed three times with alcohol, and the operation concluded as above. In presence of chromic salts, the digestion of the liquid after precipitation should be continued for three hours. Zinc salts have no influence.

Copper Smelting in Wales.

The ores vary, both in percentage of metal and in composition, according as the supplies of them arrive from various countries, says J. O'Sullivan, in the British Columbia Mining Exchange. Of all it may be said that they are sure to be accompanied by a large amount of gangue (that is, non-metallic mineral, vein-stone), which is commonly siliceous in composition. Five classes are, however, distinguished by the smelter, which must be either treated differently or carefully mixed.

Class 1.—Poor ores, containing a little copper pyrites, and a considerable quantity of iron pyrites; in these the percentage of iron and sulphur (from the two minerals) is large, copper being present only to the extent of from 1½% to 9%. For example, Norwegian pyrites, 1½% to 3½%, Rio Tinto pyrites, 3% to 6%; Seville ore, 4% to 6%; Bett's Cove (Newfoundland) ore, 7% to 9%.

Class 2.—Sulphides, carrying from 10% to 18% copper, such as New Quebrada ore, 10% to 12%; Copiapo ore, 15% to 17%; Libiola ore, 12% to 18%.

Class 3.—Richer sulphide ores, chalcopyrite, bornite, etc., running from 20% to 50% copper, for example: Chili ore, 20% to 28%; Namaqua ore, 30% to 35%; "Cape" ore (peacock), 35% to 45%; and, formerly, Anaconda ore, 40% to 50%.

Class 4.—Oxides and carbonates of copper (cuprite, melaconite, azurite and malachite) with a little of the sulphides; silicates, copper precipitates, native copper ores, that is, ores carrying a native copper (metallic copper) and copper barilla (copper sand).

Class 5.—A product of ores which have already undergone a metallurgical process abroad (fusion), and constitutes a regulus or matte, generally rich in copper, yielding from 45% to 60%, and sometimes 72% of the metal; for example, Chili regulus, 45% to 48%; Columbian matte, 47% to 49%; Montaua matte, 53% to 60%; Boleo matte, 60% to 62%; Anaconda matte, from 62% to 72% copper.

Large lots of Chili bars, assaying from 97% to 98% copper, are also melted and refined at these works; also, argentiferous Anaconda furnace-bottoms have been treated from time to time.

CALCINATION OF THE ORE.—1st Operation.—Note —This operation, the object of which is to expel the large excess of sulphur in the cupreous pyrites, and to oxidize the sulphide of iron into oxide of iron, is dispensed with in the case of the richer sulphide ores of the second and third classes.

The calcination is conducted in reverberatory furnaces, called "calciners," at a very low temperature, with free access of air. The charge, three to four tons, is introduced into the furnace by means of a hopper on the roof. After about two hours it is turned over by the paddles; this is repeated from time to time during the calcination, which is completed in twelve hours, when the charge is withdrawn. The sulphur dioxide produced in this case escapes into the atmosphere; but the poorer "cupreous sulphur" ores of the first class are calcined in automatic calciners, when the sulphur dioxide formed is carried by the air currents into the sulphuric acid chamber, and thus utilized for the manufacture of that acid.

MELTING OF THE CALCINED ORE.—2nd Operation. The charge, 42 to 46 cwts., consists of a mixture of the calcined ore and a proportion of the sulphide ores of the second class, that do not need calcining, metal furnace slag, "sharp slag," containing about 3% copper.

It is melted in a reverberatory furnace, called "ore furnace," for about six hours, whereby a regulus or matte (coarse metal or ore metal) is produced, carrying from 30% to 35% copper; and a slag, "ore furnace slag," composed of silicate of iron and earthly bases, and containing from 1% to $\frac{3}{16}$% of copper.

The metal thus produced should not contain more than 35% copper, since that would mean a small proportion of sulphide of iron (FeS), which would be likely to have oxidized copper in the slag; and not less than 30%, if possible, since that would not be economical.

CALCINATION OF THE COARSE METAL.—3rd Operation.—The charge, four tons of the crushed metal, is calcined for from twenty-four to thirty-six hours at a low heat, in a reverberatory calciner. The object of this is to oxidize the sulphur combined with iron, and the iron itself, leaving cupreous sulphide (Cu_2S) untouched; this point, however, may not be reached, or it may be overreached in actual practice. Some sulphate of copper ($CuSO_4$) is unavoidably formed in this operation. If the calcination be very imperfect, it can be corrected in the fourth operation.

4th Operation.—Melting of the calcined coarse metal in the metal furnace (reverberatory furnace), mixed with certain proportions of rich ores of the second, third and fourth classes, rich copper slag from the fifth and sixth operations (roaster and refinery slag), copper scale and siliceous matter, called "cobbing," that is, old pulverized bricks from furnaces (foul).

Result.—A rich "metal" (matte), whose copper percentage varies according to circumstances, say from 55% to 80%. These products are classified into red, blue, white and pimple metal. Red, from 55% to 65%; blue, from 65% to 72%; white, from 72% to 78%; pimple, from 78% to 80% copper. Of course, there may be every grade of quality between these estimates.

The percentage can be judged, however, by a practiced eye to within 1% to 2%. The slag from this process contains about 3% copper as silicate of copper. It is also rich in oxide of iron, and is charged into the "ore furnace" as mentioned above, when the oxide acts as a flux, and the silicate of copper is reduced to sulphide of copper.

Roasting.—5th Operation.—The pigs of fine metal, red, blue, white or pimple, as the case may be, are piled up loosely in the roaster furnace, and heated with a gradually increasing heat, the current of air rushing through at the same time. The metal, as it melts (called "sweating down") passes through the current of air, and is oxidized; sulphur to sulphur dioxide (SO_2); copper to cupreous oxide (Cu_2O); the oxidation occurs only on the surface of the drips, so when the whole charge is melted we have really a mixture of cupreous sulphide and cupreous oxide, when the reaction occurs, $Cu_2S + 2Cu_2O = 6\,Cu + SO_2$, the gas ($SO_2$) escaping through the melted charge, causing ebullition, thus bringing further quantities of Cu_2S in contact with the air; meanwhile metallic copper collects at the bottom. Metallic copper, however, is able to dissolve limited quantities of the Cu_2S, and therefore, when the whole charge becomes metallic, the same reaction continues, but slower. If tapped at this point, the reaction occurring in the pig before setting produces pimples on the surface, and is known as "pimple copper." If, however, it is

allowed to work a little longer iu the furnace, less Cu_2S will be contained when tapped. Now, the reaction occurring so slowly will not produce pimples, but raise the chilled crust iuto blisters; snch copper is known as "blister copper."

Refiuing.—6th Operation.—About teu tous of either blister or pimple copper is charged into the refinery furnace and sweated dowu; this oxidizes the large exposed surface. When melted down oxidation is continued by flapping; that is, beating the copper with a rabble-like tool, so as to expose fresh surfaces of the copper to the air. The object of this oxidation is to oxidize aud slag off impurities, such as iron, arseuic, antimouy, phosphorns, and sulphur as a gas (SO_2). But in separating these, the copper oxidizes as well, to cupreous oxide, the bath of metallic copper dissolviug it as produced. By and by the points may be reached when metallic copper will dissolve uo more cupreous oxide further oxidatiou of copper would slag copper itself. This pitch of the copper is called the "dry." A ladleful is taken ont and allowed to set, when, if it be "dry," a depression, a furrow of the surface is formed. It is brittle, aud has a brick-red, fine granular fracture. The slag is now removed from the surface, and anthracite coal is thrown upou the charge, and a greeu pole is plnnged beneath the surface. The water of the pole produces steam, causing great distnrbance, thus bringing fresh surfaces to the action of the carbon of the anthracite, as well as the pole itself. This oxide of copper is reduced to metallic copper—$2Cu_2O+C=4Cu+CO_2$.

In reality the impurities are not perfectly removed. The copper, on being perfectly reduced, is not "tough," and malleable in consequence; by an excess of poling this conditiou is brought about; the copper is then said to be "over-poled."

The fractnre of such copper would appear brass-yellow in color and coarsely fibrous.

The presence of certain quantities of cupreous oxide corrects the effect of tbese impnrities, so the poling is carried only to that point where sufficient oxide of copper is present to balance the irou, arsenic, etc., this being now called the "tough pitch."

If that pitch shonld be passed, it is restored by giving a little air. The refiner decides by taking a "test," a small ladleful, which he cools and hammers, then breaking it in a vise. The fracture should be finely fibrons, silky and pale salmon color. There are three qualities of commercial copper, viz.: "Tongh pitch," as produced above; "best select," a pure copper for best brasses, and "tile," a very impure copper, for hard brass. The "best select" is made from a selected regulus, made in this way: Ordinary white metal partially roasted until some metallic copper is formed as a bottom under the reguln, copper having a greater affinity for sulphnr than the other metals present; the metallic copper will contain most of these, leaving the regulus exceptionally pure; this being stripped off from the bottom, is roasted by itself to "blister copper," which, when refined, is "best select." The impure copper being refined, makes the "tile copper."

In addition to extensive reverberatory copper smelting plant, for many years several water-jacket furnaces in full blast have been prodncing copper matte carrying from 50% to 56% copper.

This matte is crushed fine and six-tou charges of it calciued in the modern automatic "revolving calciner," in which a most perfect calcinatiou is effected in about twelve hours. The calcined product is subsequently reduced to metallic copper by a special treatment. They have also in operation two converters, in which very poor "purchasc" matte, carrying 12% to 15% copper is blown into white metal of 75% copper in about fifty minutes—the color of the flame issuing from the converter iudicating the desired pitch of the metal. The total cost of the production of refined copper from the ore is abont £7.10.0 per ton (abont $36.52).

The methods of copper assaying employed are: "Cyanide," "battery," "subsulphide" and "iodide." The old Cornish copper assay (fire assay) is still practiced.

Iron Ore Situation.

At mines everywhere in the Lake Superior regiou stock piles are large, some so big that all available room is exhausted, says the American Manufacturer. At these uo hoisting is under way. Others have far more ore than usual and these are runniug light. There is far more ore on hand in the regiou, comparative to output, than has been the case in auy fall for eight years; probably more, actually, than ever known.

Final returns regardiug irou ore shipments by lake for 1903 show au aggregate of 23,649,550 gross tons. This does not include 203,419 tous shipped from the Lake Superior Consolidated mines on the Michipicoten range in Canada. Neither does it include the shipments by rail to furnaces near the mines, which are estimated at about 450,000 tons. With these two items added, the grand total will be 24,000,000 tons. The graud total of shipments during 1902 was 27,571,121 tons, of which 27,039,169 tons were by lake; therefore the lake shipments this year are 3,389,619 tons less than they were last year. Various causes contributed to this, the principal one beiug that more ore was brought down last year than was needed, and the snrplns had to be added to the available supply for consumption this year. Of the 203,419 tous shipped from the Michipicoten range 170,672 tons went to Lake Erie ports.

In view of the depression iu the iron and steel iudnstry, the stocks of ore on Lake Erie docks is not as discouraging as was expected. The reduction of more than 3,000,000 tons iu the ontput of Lake Superior mines this year as compared with 1902 has been instrumental in keeping down the Lake Erie dock stocks. Reports from all Lake Erie dock stocks show that of the total ontput of 23,649,550 tons of ore by lake, they received 19,681,731 tons and had a balance on dock December 1 of 6,371,085 tous. In 1902 they received 22,649,424 tous and held a balance December 1 of that year of 7,074,254 tons. There are no definite figures as to stocks of ore at the furnaces, but a large snrplus—both at furnaces and Lake Erie docks—mnst be looked for next spring in the absence of decided improvement in the iron business.

There was a falliug off in the shipments to furnaces duriug the navigation season just closed. Shipments to furnaces between May 1 and December 1 of this year aggregate 16,903,013 tons, compared with 18,423,364 tous in 1902, 14,204,596 tons in 1901, 11,613,773 tons in 1900 and 11,765,158 tous in 1899.

Accuracy of Commercial Samples and Assays.*

Written by ERNEST H. SIMONDS.

NUMBER II.—CONCLUDED.

PYRITIC CONCENTRATES.—Whether an umpire assay is necessary depends upon the results of the seller's and buyer's assays, with reference to the richness of the material, and npou the weight of the lot. In general, an umpire assay is not made if the assay valnes given by the two assayers do not vary more than 0.05 ounce of gold per ton of concentrates, provided the value of the lot figured from the results of the two assayers differs by less than $20, or provided the variatiou is less than 1% of the total value of the lot.

Tbe most commou cause of difference between duplicate assays of the same conecntrate pulps is that these pulps often contain particles of amalgam, due to scouring of the plates, or particles of rather coarse gold which have escaped amalgamation. These rich particles are especially common iu concentrates at the present time, as modern practice emphasizes the use of coarser screens thau were formerly nsed, the purpose being to increase the tonnage capacity per stamp. Concentrates are always ground to pass a 100-mesh screen for the assay pulp, but the extremes of results of four careful and correct assays of such conceutrate pulps from some mills will often vary several teuths of an ounce of gold per ton of coucentrates, while those from other mills will give closely agreeing or identical results on repeated assays. But when 100-mesh pulps which do not give uniform results are reground to pass a 150-mesh screen, the differences disappear and the results for gold agree exactly, or at least all lie within one-tenth of an ounce per tou. The following results on different lots of sulphurets from two mines—A and B—will illustrate this point:

	100-Mesh				150-Mesh			
A.....	2 36	2.44	2.30	2.30	2.24	2.96	2.26	
B.....au	1.48	1.22	....	ag 58.20	57.84	au 1.32	1.32	ag 57.74

It is apparent that the present practice of using a 100-mesh screen for concentrates should be changed to the use of a 150-mesh screen—preferably a box screen. Although this would require somewhat more labor iu grinding the pulps, it would lesseu the labor of assaying by reducing the number of assays required to obtain a reliable average. The fiue screen does the averaging of several hundred or thousand grams, while averaging the assay results of the coarse pulps gives an average of only one or two assay tous. More important yet is the close agreement in the results of the two assayers—provided their assays are correct.

SILVER-LEAD ORE AND CONCENTRATES.—This is the easiest of materials to sample and gives perfectly uniform results. The silver is nsually estimated by the scorification and the gold by the crucible assay. The lead is estimated by fire assay at present, although within a few years perhaps the fire assay will be displaced by the molybdate method. However, the fire assay, if skillfully performed on an ore free from other easily reducible metals, will give results checking within ½%, and results only ½% to 1% below the correct percentage as given by the molybdate method. In the following table 1 and 2 are from Idaho and 3 and 4 from Mexico:

No.	SELLER Oz. Ag.	SELLER %Pb.	BUYER Oz. Ag.	BUYER %Pb.
1	67.5	63.2	69.4	62.8
2	72.4	64.5	72.8	64.3
3 ..... Original	311.00	36.3	312.50	36.5
4 ..... Duplicate	230.50	30.2	.....	.....
4 ..... Average	234 90	30.65	235.50	30.75

Iu 3 and 4 the assayers worked on the same pulps, but iu 1 aud 2 the results show the discrepaucies in resampling the whole carload of 25 tons of coarse ore, as well as in assaying.

Let us now turn from the discussion of the accnracy of assays to a discussion of the accnracy of ore samples. It is a commou practice to make duplicate assays, but in only a few cases is the sampling dnplicated or checked iu any way. Results show that carefnl, every-day samples are, on the average, correct within about 2% of the total amount of metal present. The following checks on samples were obtained in the course of regnlar work, where time was an object and no more than ordinary care was taken.

COPPER MATTE.—Five hundred pounds of matte, crushed to pass a 1-inch mesh and well mixed by previous crushing and couing, were quartered ou an iron floor by the nse of a rectaugular iron cross. Two of the quarters were quartered to 50 pounds, crushed to pass 4-mesh, qnartered to 6 pounds, dried, gronud to pass 60-mesh, aud from this ½ pound was taken out by dips from the original pnlp. The other two quarters were worked down in the same way for the duplicate pulp. The two pulps were assayed as separate samples:

	Ounces Gold.	Ounces Silver.	Per Ct. Copper.
Original.....	35.50	342.0	52.72
Duplicate.....	35.64	337.6	52.78

The whole lot, of which these were samples, weighed 22 tons and was worth about $25,000.

PYRITIC CONCENTRATES.—A lot of 30 tons of concentrates, free from coarse gold or amalgam, was sampled in the usual way. The seller, believing this sample to be too low, had the whole 30 tons resampled. The method pnrsned was exactly the same each time and was as follows: The lot was dumped from the sacks onto the sampling floor into a compact heap, 2 to 3 feet high. Every fifth shovelful was taken as a sample and coned. The cones were then flatteued and every third shovelful takeu as the sample and again coned. These cones were flattened, alternate shovels being taken as the sample, and thrown on the center of a rectangular cross, and from this point ou quartered down to a weight of 5 pounds. This 5-pouud sample was steam-dried and ground to pass a 100-mesh sieve. The assay pulps were takeu out by dip samples:

	SELLER Ounces Gold.	SELLER Ounces Silver.	BUYER. Ounces Gold
First sample.....	7.07	27.50	7.17
Re-sample.....	7.29	28.05	7.16

CHECKS ON COMPOSITE PULPS.—Many of the best engineers, after getting the assays of a lot of mine examination samples, direct the assayer to make a mixture of eqnal portions of certain samples, which they have decided upon as lying within the limits of an ore body, for making a laboratory working test. The assay of a pulp of this composite sample, compared with the average assay of the constituent samples, checks the sampling and assays of all the samples. The following table gives checks obtained in this way. All these samples are quartzose ores from the examination of large mines:

No. of Samples	HIGHEST. Ounces Au.....	HIGHEST. Ounces Ag.....	LOWEST. Ounces Au.....	LOWEST. Ounces Ag.....	AVERAGE. Ounces Au.....	AVERAGE. Ounces Ag.....	COMPOSITE. Ounces Au.....	COMPOSITE. Ounces Ag.....
102...1.10	47.40		0.02	0.25	0.213	6.79	0.225	6.70
16...0.40	.....		0.06	....	0.204	....	0.21	....

Eqnally satisfactory agreement may be obtained with composite samples of free gold ores.

In the second a laboratory test showed 22.8% of the gold to be free and 50.4% to be contained in the sulphurets. In the first the ore is typical cyaniding ore, containing very fine gold and less than 1% of sulphnrets.

CHECKS ON ORE TESTS.—In making laboratory mill tests, where the free gold and the percentages and values of concentrates, tailings and slimes are determined, the total valne ought to foot up to within 2% or 3% of the valne given by the assay of the ore pulp.

Althongh the results to be obtained by assays fall short of the accuracy one might wish, this is due largely to the miuute amounts one mnst take for samples. The idea of the gold miuer of the last generation, that the value of the ore standing in the miue could be determined ouly by actually milling it, arose from careless and haphazard sampling and incorrect assayiug. The trained and experienced engineer places absolute and justifiable confideuce, within a proper limit, in his estimate based on his samples and surveys of ore in sight. Smelting works buy hundreds of tons of valuable ore daily on the samples alone, and pay cash for it before they begin to work it. In fact, improvements in sampling and assaying have led the way to, and in some cases eveu made possible, improvemeuts iu working ores. The cyanide method, in its conception and rapid development, affords a conspicuous example of the value of accurate data and knowledge of the control of operations which were furnished by sampling and assaying.

THE occurrence of antimony in an ore of gold or silver renders its treatment by the cyanide process difficult.

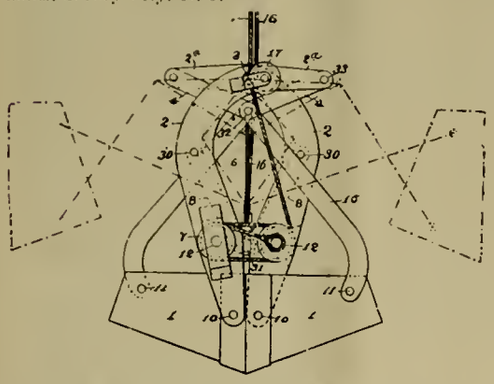
*California Journal Technology.

Mining and Metallurgical Patents.

PATENTS ISSUED DECEMBER 22, 1903.

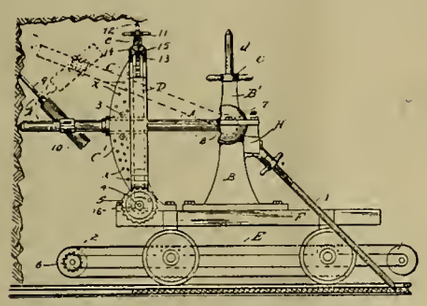
Specially Reported and Illustrated for the MINING AND SCIENTIFIC PRESS.

EXCAVATING BUCKET.—No. 747,480; H. L. Reynolds, Jersey City, N. J.



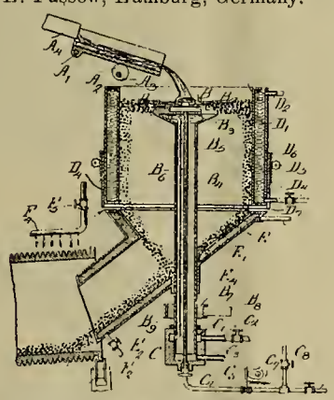
An excavating bucket comprising two opposed scoops, swinging hangers pivoted to scoops, and means controlled by conjoint action of both hangers to control angular position of scoops.

APPARATUS FOR EXCAVATING ROCK.—No. 747,867; C. T. Drake, Chicago, Ill.



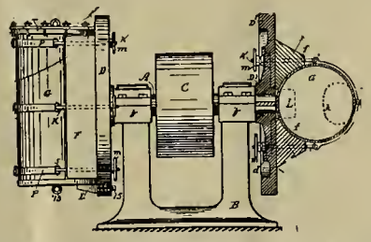
In apparatus for excavating rock, combination of car, F, upright ring support, D, disk, C, open slot through middle of disk, bar, A, extending through slot, means to resist lateral motion of bar lengthwise of slot and means for turning disk and holding same in adjusted positions.

CEMENT AND PROCESS OF PRODUCING SAME.—No. 747,920; H. Passow, Hamburg, Germany.



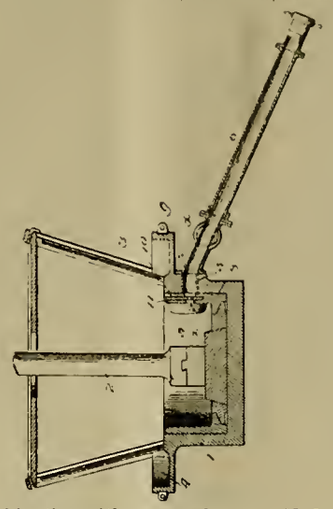
The cement process which consists in disintegrating highly heated furnace slag into particles, in projecting same through cooling fluid into impingement upon surface and in cohering same.

MECHANISM FOR TREATING ORES.—No. 748,528; G. M. Rice, Worcester, Mass.



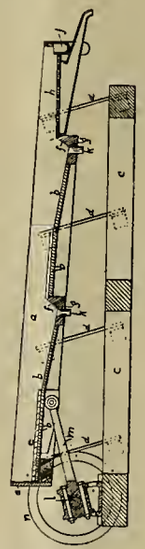
Machine comprising rotatable shaft, supporting bearings therefor, operating wheel or pulley fixed on shaft between bearings, heavy rimmed head wheel mounted on each end of shaft, hollow-faced supporters fixed upon head wheels and adapted for seating ore container cylinder, removable ore container cylinders, clamping devices for respective ends of cylinders, comprising bands that clasp around outer surface thereof and terminate in threaded draw bolt portions confined in wheel rims, and screw nuts on draw bolts for tightening and loosening clamping devices.

DISCHARGE FOR STAMP MACHINES.—No. 747,703; J. L. Harris and J. W. Shields, Hancock, Mich.



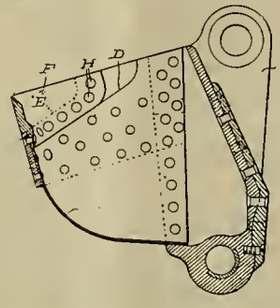
In combination with ore crusher provided with discharge opeuing, straight discharge pipe in line with discharge openiug and having valve casing near upper end, valve of approximately cylindrical form mounted in valve casing and having opening therethrough to aline with and form part of bore or opening through discharge pipe, means for operating valve, controlling means applied to lower portion of discharge pipe for interrupting passage therethrough, and iujection pipe in communication with upper portion of mortar and arranged to deliver jet within mortar across discharge pipe to prevent escape of slimes while permitting free outflow of metal.

MOVABLE SLUICE BOX.—No. 747,692; F. Francois, St. Etieune, France.



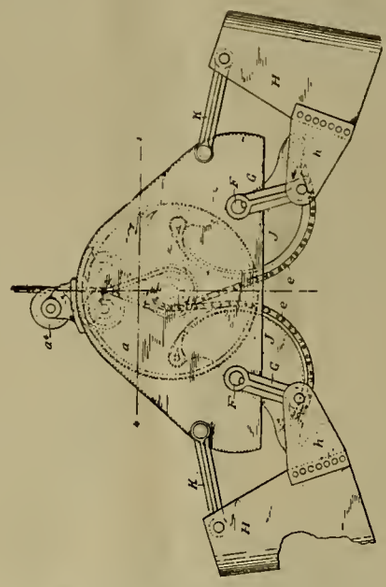
An ore separator, comprisiug rectangular cradle having sections of its bottom carrying bars for breaking up earth, intermediate rectaugular slanting sections leadiug from one section and connected abruptly with next, and means for oscillating cradle and elevating it in horizontal plane during oscillatiou.

DREDGER BUCKET.—No. 747,719; F. Z. Hunt and H. J. Reiling, Elizabethtown, N. M.



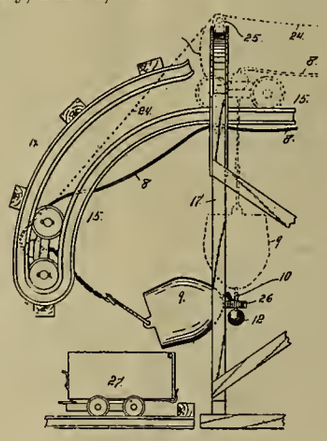
In dredger bucket, combination with bowl and reinforcing member secured thereto and projecting beyond free edge thereof, of recess in reinforcing members, lip fitting recess and offset flange on lip adapted to rest upon edge of bowl and to be secured to inner face of reinforcing member.

CLAM SHELL BUCKET.—No. 747,819; G. H. Williams, South Brooklyn, Ohio.



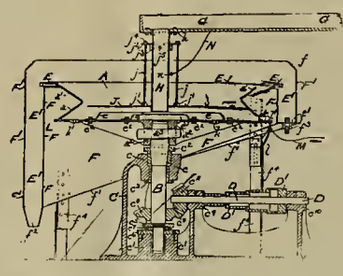
In clam shell bucket, combination of frame, scoop member, power wheel, shaft mounted in frame, rear end of scoop member being movably suspended from frame and front end of member being connected with shaft, power wheel and shaft being operatively connected.

BUCKET DUMPING APPARATUS.—No. 748,558; H. K. McCaughey, Denver, Colo.



In bucket dumping apparatus, combiuation with bucket carrying car, track having curved downwardly-extending loop located at one end, loop members being parallel and adapted to engage car wheels at two diametrically opposite points, bucket connected with car and provided with dependiug part, and means located in rear of track loop for catching depending part and holding same during the bucket-dumping act.

AMALGAMATING MACHINE.—No. 748,456; S. Alford and J. J. R. Smythe, Johannesburg, Transvaal.



In combination, pan A, concentric upwardly and inwardly inclined rings e e′ of less height than rim of pan, lip E round top of pan, two concentric cylinders forming chamber E′ to receive pulp as it leaves pan, adjustable disk J, launder G and pipe H discharging over center of pan beneath disk, metal baud L round base of pan A, stationary bracket l, brush l′ connected with electric wire M and bearing against band L for making electrical conuection with rotating pin, and electric wire N connected with pipe H for passing current electricity through pan and contents.

Mining Summary.

SPECIALLY COMPILED AND REPORTED FOR THE MINING AND SCIENTIFIC PRESS.

The United States Census Bureau last week issued a preliminary report on the mining of quicksilver, flint feldspar and fuller's earth for the calendar year of 1902, and shows 34,291 flasks of quicksilver (each weighing 76½ pounds), valued at $1,467,848, together with 11,727 short tons of cinnabar, valued at $82,642; 36,365 short tons of flint, valued at $144,299; 45,287 short tons of feldspar, valued at $250,424; 11,492 short tons of fuller's earth, valued at $58,144.

The United States Director of the Mint includes the following in his annual statements of the approximate distribution by producing States and Territories of the products of gold and silver of the United States for the calendar year 1903:

State or Territory.	Gold.	(Commercial Value.) Silver.
Alaska	$ 6,921,157	$ 16,540
Arizona	4,784,000	1,932,115
California	16,535,525	497,664
Colorado	22,000,000	7,517,812
Idaho	2,067,183	3,415,000
Montana	4,134,367	5,400,000
Nevada	3,576,227	2,376,000
New Mexico	372,093	151,200
Oregon	1,364,341	67,500
South Dakota	2,889,137	179,965
Utah	5,036,599	8,100,000
Washington	434,109	164,700
Totals (including minor States omitted)	74,425,340	30,520,688

The principal increases and decreases for the year compared with 1902 are shown as follows:

Alaska—Gold, decrease $1,424,000; silver, decrease $32,000. These decreases are due to the season in which running water was available being a month shorter than other recent years.

Colorado—Gold, decrease $6,428,000; silver, decrease $791,000. These decreases were due to the miners' strike, which greatly interfered with production.

Idaho—Gold, increase $592,000; silver, increase $812,000.

Nevada—Gold, increase $681,000; silver, increase $391,000.

Montana—Gold, decrease $245,000; silver, decrease $1,619,000.

Utah—Gold, increase $1,470,000; silver, increase $2,360,000.

Washington—Gold, increase $162,000; silver, decrease $164,000.

South Dakota—Gold, decrease $4,076,000.

Oregon—Gold, decrease $452,000.

A total net decrease is shown in the gold production of $5,575,000, and net increase of $1,100,000 in the production of silver.

ALASKA.

R. Onffroy of the Pacific Alaska Transportation & Coal Co. says they have contracted to deliver at their proposed new coal hunkers on Herendeen bay during the year 1904 a minimum of 40,000 tons of coal from their coal mines on Portage hay. This will necessitate increase of development work at the mines, the completion of tide water improvements and building the proposed coal carrying railroad. By May 1 it is expected to deliver coal at the coal hunkers on Herendeen bay. Materials for the railroad, the wharf and the bunkers are being shipped. The railroad will be 17 miles in length. The route has been surveyed and mapped out.

The Alaska C. Co. will increase development work on the Bonanza copper group in Copper river section, near Valdez, the coming season, says S. Birch, manager. Machinery will be put in. If the ground develops satisfactorily the company will huild a railway to it.

ARIZONA.

Graham County.

C. A. Ross, president of the Standard copper mines, near Clifton, says the Standard Con. C. Co. has been formed for the purpose of merging the Standard copper mines, the San Jose group of mines and those of the Coronado C. Co. C. A. Ross is president of the consolidated company. This merger does away with the litigation pending hetween the Standard C. Co. and W. B. Thompson and I. Cascarelli over ground claimed by hoth parties, and it will also allow the working of the San Jose mine from the underground workings of the Standard, which are nearing the San Jose line. By this arrangement the San Jose mine can he opened at depth without additioual hoisting plants.

Maricopa County.

(Special Correspondence).—Wilson & Baker are developing a group of claims near the Agua Fria river, northwest of Phœnix.——The White Cloud mine, near Hot Springs Junction, has resumed operations.——Walker & Carguile are at work on gold claims in Cave Creek district.——Goldfield reports say development work is in progress on a number of properties in that section of the county.

L. R. Legier will put men to work on a lead property near the Horton mine, northwest of Peoria. Considerahle work has heeu done on this mine and there is a hody of high-grade lead ore opened up.

The Hassayampa M. Co. is working men on its group on the west side of the river near the railroad.——Preparations are being made for cyaniding the tailings at Seymour, on the Hassayampa river, near Morristown.——The Lime Creek C. Co. is working men on several claims at Copper Top, north of Phœnix. Copper ore is being taken out for shipment to the smelter.——More men have been added to the number at work at the Black Hawk mine, in White Tank mountains. Development is progressing.

R. E. Humphries, operating near Morristown, reports that he will put more men to work on his group next week.——Men are at work at the Angel mine, west of Wickenhurg. A hody of copper ore has been opened.——The Michigan G. M. Co., which have heen operating placer machines near Morristown, have suspended operations indefinitely.——C. Hall is working men on claims near Goldfield.

A. S. Mills is getting out shipping ore from his mine in Cave Creek district. The ore contains values in copper, gold and silver.——Moore & Linville are working the Mexican mine, near Cave Creek. Ore is heing ohtained.——The cyanide plant near Wickenhurg is in operation.

Phœnix, Jan. 2.

(Special Correspondence).—The White Cloud mine, near Morristown, is working a force of thirty men,

Phœnix, Jan. 4.

Mohave County.

The mill of forty stamps completed in Decemher hy the Mohave G. M. Co. was started last week, and the full forty stamps are dropping on ore from the Leland mine of the company. The mines of the company are in San Francisco district, near Acme, and in the same section with the Gold Road M. Co. The ore is hauled by the company's railroad from the mine to the mill.

Five hundred cords of wood are heing rafted down the river from Cottonwood island and up river points for the New Comstock M. Co., near Kingman, which will resume operations next week. The 20-stamp mill is heing put in order to handle forty tons of ore per day, the cyanide tanks not being adequate to handle a greater output.——Superintendent W. O'Dea reports opening up a hody of silver-gold ore on the Mariposa mine, of the Oro Plata group, in Todd hasin, near Kingman. He has a carload of the ore on the dump and is preparing it for shipment to the smelter. J. W. Gerritt is owner.

A. J. Doran of Prescott, manager of the Nighthawk mine, has men at work. A tunnel from the gulch below is under consideration to get at least 1800 feet in depth. By running this tunnel a heavy haul over a rough road will he avoided.

G. Q. Adams has an option, for Denver, Colo., men, on the J. F. T. mines, near Stockton hill, and has put men to work on development.

Santa Cruz County.

Concentrates are heing shipped from the Arizona G. & C. Co. mill at Salero with a twelve-horse team. H. L. Vaughn is general superintendent.——W. E. Balcom, superintendent of the Salero M. Co., is preparing to sink shaft No. 2 on the Darwin mine.

CALIFORNIA.

California coal and fuel oil statistics are reported hy the San Francisco Call from the annual fuel review of J. W. Harrison as follows: The quantity of coal reported during the year is 230,044 tons less than 1902. This cannot he accepted as the amount of fuel to fill the requirements of the State, as the quantity of fuel oil which was produced in 1903 has been 60% in excess of the products of 1902. During the early part of the year labor disturhances occurred in the British Columhia collieries. The ahrogation of the duty of 67 cents per ton on Australian and British Columhia coals has proved a marked advantage for their products and has aided in giving large consumers a pronounced henefit. The duty expires Jan. 15, 1904. The varions sources of the coal supplies were as follows:

	1902. Tons.	1903. Tons.
British Columbia	591,732	289,890
Australia	197,328	276,186
English and Welsh	95,621	61,580
Scotch	3,600	3,495
Eastern (Cumberland and Anthracite)	24,133	13,202
Seattle (Washington)	165,237	127,819
Tacoma (Washington)	209,358	256,826
Mount Diablo, Coos Bay and Tesla	111,209	84,277
Japan, and Rocky Mountains, by rail	47,380	102,219
Total	1,445,598	1,215,554

It is estimated the California products of oil for 1903 will foot up hetween 20,000,000 and 21,000,000 harrels, as against 13,000,000 for 1902.——The total deliveries of coke hy water amounted to 68,090 tons, as against 64,916 tons in 1902. Fully 75% of this amount was shipped from England and Germany, the halance principally from Belgium and Australia.

Amador County.

Several placer mines near Volcano are ready to start, hut are waiting till the Debris Commissioners approve the restraining dams, says the Ledger.

At the Kennedy mine at Jackson, at the east shaft the additional twenty stamps to the mill are nearing completion. The mortars are in place, also the concentrators. It is expected these stamps will he started Feh. 1st. A cleanup room is arranged in the central part of the addition, and from this room all the hatteries, plates and concentrators are in view. The sulphurets as they are gathered from the concentrator troughs, are dumped in a loose state through an opening to the floor of the sulphurets building, where they are sacked, loaded on wagons and taken to the chlorination works. Between three and four tons of sulphurets are saved per day at each mill, making seven tons per day with the present milling capacity of eighty stamps. With 100 stamps the output of sulphides is expected to reach ten tons daily.

Butte County.

R. E. Cranston et al., who hought part of the Beeny place, 6 miles east of Marysville, on south side of Yuha river, and have had prospecting drills at work on the land, have a hond on part of the C. J. Hastings land and also a hond on 240 acres owned hy Reynolds & Norton. This gives the Cranston Co. a strip of land 2 miles in length, extending along the levee and channel of Yuha river. It is proposed to work the gravel hy gold dredger.

El Dorado County.

Turney & Co. have made final payment on the Beckman Hill mine, at Pleasant Valley, and it is oxpected work will begin this week. The mine is said to show a 4-foot ledge that assays $4 a ton at the croppings. A mill and hoisting works will he put up in the spring.

Fresno County.

The oil production of the Coalinga fiold for the year 1903 is given at 2,075,000 barrels; numher of producing wells, 115; number of new wells brought in during the year, 46; numher of wells drilling, 30. The production hy months was:

	Barrels.
January	46,500
February	42,000
March	46,500
April	90,000
May	133,000
June	221,000
July	212,000
August	248,000
September	267,000
October	259,000
November	250,000
December (estimated)	260,000
Total	2,075,000

The Bakersfield–Point Richmond pipe line of the Standard Oil Co. is at present carrying only Coalinga oil, and reports indicate there is sufficient of this oil on hand and being produced to keep the line in operation for some time yet. The chief trouhle with the line, says the Oil Reporter, seems to be that it is not large enough to handle the quantity of oil awaiting transportation. While the pipe line is idle from Coalinga south, oil is heing shipped in large quantities hy rail.

Kern County.

Telluride ores are reported found in the La Crosse mine, near Randsburg.——C. H. Snow has put in a gasoline engine in the Kinyon mill.

Nevada County.

The Loutzenbeiser ranch of 220 acres has heen hought hy the North Star M. Co., together with the Loutzenheiser interests in the Lemarque mine, near Grass Valley. The ground adjoins the property already owned hy the North Star Co.

J. F. Waterhouse of the Ethel mine at Gaston Ridge says a drift is heing run on the Ethel to cut the shaft. In the spring operations will he increased and additional machinery put in.

The California mine, near Washington, is employing sixty men. Thirty stamps are dropping regularly and ten more will he added in the spring.

San Bernardino County.

The Pacific Borax Works at Borate have seventy-eight men at work and $2.25 a day and hoard is said to be the scale paid.——The Bartlett Borax Works at Borate expects to start up this month.

San Mateo County.

The Wisconsin Oil Co. will start drilling several additional wells at Half Moon Bay. The company has one well completed, which is producing. The Paxton Oil Co. well is producing. J. E. Kerr of San Francisco is manager of hoth companies.——The Guiherson, Saylee and Haine wells, iu Purissima canyon, northwest of the wells on Tunitas creek, are getting in supplies and materials for drilling additional wells—Nos. 8 and 9—to be located one-fourth of a mile from their present producing wells.——The Pilarcitos Oil Co. is working again, after experiencing difficulty in getting fuel.

Santa Barbara County.

The Union Oil Co. is preparing to ship its product to Alcatraz Landing through the Western Union pipe line via Careaga. A pumping plant is being huilt at Graciosa from which point the oil is forced to Careaga. The Lompoc product will also go hy same route.——The Western Union Co. is sinking 8-inch casing on well No. 18, which is down 520 feet. Preparations are under way for putting in several more rigs.

Santa Clara County.

A body of ochre is reported found on the O. N. Nelson place, 14 miles northwest of Gilroy. It will he developed for use as paint.

Siskiyou County.

Fry & Macaulay are sinking a shaft on the Sheha quartz mine at Patterson creek, near Fort Jones. The shaft is down 100 feet, showing ore.

Cold weather, says the Yreka Journal, has interfered with mining operations, especially in the placer claims, on account of the water supply freezing.

The miners at Hawkinsville on Rocky and other gulches report a good supply of water. Last week the cold weather stopped operations for several days on account of freezing. The water was turned out of the Greenhorn ditch to prevent freezing, hut was turned in again Jan. 2, the weather moderating. Free water is also running again in several gulches, especially Canal and Long gulches. Most of the work is sluicing, hut one claim is worked hy hydraulic giant.——Tho Willard mine at Hamburg Bar has been leased to C. & L. Rasmus.——The two Chinese companies operating placers near the Lowden ranch are working steadily. One of these claims has been in continuous operation for thirty years, says the Journal.—The Portuguese mine, on the Klamath river, owned hy Wood & Cuddihy of Happy Camp, has heen leased to Fort Jones men.——The Pacific Mines Co. of Chicago, Ill., which bought the Fort Goff Bailey placer mines in Seiad district, made the final payment of $5000 last week, giving them title toa body of placer ground, with river frontage of 3 miles, comprising 300 acres. This mine is heing worked at the Fort Goff claim, under Superintendent J. W. Martin.

The Minetti B mine, below Nolton, is heing operated under lease, with E. Feheley as superintendent. A body of blue gravel has heen struck.——Preparatory work is going on at the Van Brunt or Ah Ock placer mine, near Happy Camp. D. I. Jackson of New York is manager.

Tulare County.

(Special Correspondence).—C. B. Rogers, having bought tho Bald Mountain, Richelieu, Eclipse, Eurilda and other claims near White River, has built and equipped a hoisting plant on the Eclipse mine. He is retimhering the old shaft, which is down to depth of 400 feet. On the Bald Mountain a douhle, 4-foot, compartment working shaft is heing sunk. A hoisting plant is heing put up on that mine also.

White River, Jan. 5.

Tuolumne County.

The Tuolumne Chief Con. G. M. Co. has been incorporated, with offices at Los Angeles, hy F. Danford, A. C. Sweet, L. D. Bathwell, A. R. Swett and W. W. Jamison, to operate in Tuolumne county.

A 4-stamp mill is heing built at the Kanig mine, near Columhia, which is heing operated by Superintendent Wilhelm.——S. C. Syndegard has started operations on the Rockwood pocket mine (formerly the Hastings & Kenny), at Yankee Hill, near Columhia.——H. M. and W. Cullers have hought the F. C. Cullers interest in the Little Beauty mine near Arrastraville.

COLORADO.

The past year has shown an increase in the production of Colorado's oil fields of 250 harrels per day. There has been no increase in the oil-producing territory of the State within the year, but both the Florence (Fremont county) and Boulder (Boulder county) fields show larger pumping. Florence district has produced several new wells in the past few months. The output of the Florence field for the year is stated at 1500 harrels of crude oil daily and that of Boulder at 125 harrels per day, or totals for the year of 547,500 harrels from Florence and 45,625 from Boulder, grand total heing 593,125 harrels, worth about $800,000.

Mining machinery was made in Denver during the year to value of $1,500,000 and mining machinery sold in Denver was valued at $9,000,000. Pouuds of pig iron pro-

duced in Colorado, 476,533,363; pounds of steel rails made, 250,519,252.

Colorado bullion operated on at the Denver Mint during 1903 was:

County.	Gold.	Silver.	Total.
Boulder	$ 67,696 19	$ 401 88	$ 68,101 07
Clear Creek	28,851 81	199 98	29,054 79
Chaffee	27,036 23	100 41	27,136 64
Conejos	588 07	8 15	597 12
Dolores	996 85	13 21	1,010 09
Gilpin	237,515 34	1,450 10	238,965 44
Gunnison	409 22	3 27	412 49
Garfield	96 08	1 51	97 59
Lake	11,996 24	134 15	12,130 69
La Plata	18,261 73	131 54	18,393 27
Montezuma	1,466 78	2 27	1,469 05
Ouray	1,635,119 38	18,329 80	1,053,779 18
Park	12,620 25	57 73	12,677 98
Routt	19,289 10	38 57	19,327 67
Saguache	1,178 39	19 55	1,197 94
San Juan	148,591 58	250 77	118,815 35
San Miguel	1,122,581 81	13,227 17	1,135,809 01
Summit	121,151 11	838 09	122,289 20
Teller	7,555,838 48	916 81	7,556,785 29
County unknown	111,439 03	2,398 31	113,837 97
Smelter deposits	1,272,353 71	458 93	1,272,812 64
Totals	$12,725,711 61	$39,015 86	$12,764,730 47

The bullion output of Colorado for 1903 is reported by the Denver Post as follows:

	Gold.	Silver.	Lead.	Copper.	Totals.
American S. & R. Co. (Colorado)	$ 8,828,598 57	$5,990,305 92	$3,939,174 18	$ 909,057 25	$19,175,135 92
Ohio & Colorado Co. (Salida)	258,034 52	419,246 07	592,525 53	33,222 81	1,383,008 93
United States Mint	12,725,714 61	39,015 86	...	...	12,764,730 47
U. S. Smelting Co. (except zinc)	51,675 00	146,877 50	192,870 00	65,200 00	146,622 50
Boston & Colorado Co. (gold in mint returns)	...	234,394 38	...	195,271 43	429,665 81
Colorado ores treated in Utah	9,640 07	129,206 80	2,765 18	...	141,312 05
Gold not included in above	500,000 00	...	...	...	500,000 00
Totals	$21,873,662 77	$6,968,083 53	$4,727,334 89	$1,101,751 49	$34,810,432 68
Total value of zinc (partly estimated)					1,374,600 00
Add to Salida plant estimate for nine days in December not included in general statement					80,000 00
Total					$36,264,943 68

The American S. & R. Co., with its Globe, Grant, Puehlo, Elders, Philadelphia, Arkansas Valley and Durango plants in Colorado reports its total production of metal for year 1903:

SOURCE OF ORES.	Net. Pounds.	Gold. Ounces.	METAL CONTENTS. Silver. Ounces.	Lead. Pounds.	Copper. Pounds.
Colorado	1,510,066,616	402,932	11,252,552	0,907,037	6,580,125
Arizona	143,666	45	15,800	21,089	2,473

The coal production of Colorado for 1903 by counties was:

Name of County.	Total Tons.
Boulder	821,772
Delta	6,000
El Paso	201,289
Fremont	669,650
Garfield	127,951
Gunnison	457,975
Huerfano	1,243,591
Jefferson	17,372
Larimer	1,000
Las Animas	3,512,743
La Plata	140,773
Mesa	19,937
Montezuma	450
Pitkin	344,581
Weld	106,610
Total	7,671,691
Number of mines in operation	169
Tons of lignite coal produced	1,148,493
Tons of semi-bituminous coal produced	1,211,779
Tons of bituminous coal produced	5,261,025
Tons of anthracite coal produced	49,797
Tons of coal estimated from mines not reporting	129,000
Total tonnage of coal produced	7,671,691
Total tons of coke produced	716,125
Number of employes in and at mines	10,290
Number of employes at coke ovens	1,350
Number of fatal accidents	40
Tons of coal lost by strike to Jan. 1, 1904	1,125,000

The coal business of the past year shows an increase over that of 1902, says the Denver Post, notwithstanding the strikes which have cut down the usual tonnage. The Colorado Fuel & Iron Co. produced 4,810,000 tons, which is above its output for 1902. Its coke production, however, shows a small decrease. During the past year the company opened up one new mine—the Quatro, in the Trinidad district. It is now opening up a new mine in Canon City district.——The Northern Coal & Coke Co., whose most extensive properties are in the northern field, produced 839,083 tons, distributed as follows: Boulder county, 647,551 tons: Weld county, 32,522 tons: Huerfano county, 36,306 tons; Las Animas county, 122,704 tons.—— During the past year 100,000 acres of coal land in Routt county have been taken up, preparatory to the Moffat railroad entering that county. No development has been done, for the fields are yet too remote from a railroad.

Clear Creek County.

The Wisconsin mine on Republican mountain, near Georgetown, continues producing a good tonnage and several lessees are steadily at work. The smelting streak which was opened last month is improving, being 18 inches wide. J. J. White & Co. have control. The tunnel is being driven by contract and is in 1050 feet. The ore being taken out carries 175 ounces in silver per ton, with lead values.

Gilpin County.

The list of the stamp mills of Gilpin county is given as follows by the Central City Register-Call:

Mills.	Location.	Stamps. Slow.	Rapid.
Climax	Black Hawk	25	..
Fullerton	"	33	..
Hidden Treasure	"	75	10
Meade	"	40	..
Polar Star	"	40	..
Eagle	"	..	35
Boston & Denver	"	..	80
Gilpin	"	50	..
Rocky Mountain	"	25	..
New York	"	50	20
Randolph	"	50	..
Penn	"	50	..
Iron City	"	..	25
Bonanza	Chase Gulch	25	..
Perigo	Gamble Gulch	..	35
Peterson	Lump Gulch	15	..
Avon	Nevada Gulch	..	90
Mountz & Pal	Pine Creek	..	10
Totals		478	245

This shows a total of 723 stamps, which handle, together with the Rocky Mountain concentrator plant, a total of 1000 tons of ore daily, and most of these stamps have been dropping steadily during the past year. During the year five new plants were built, one on North Clear creek, one at Delmonico mine on Quartz hill, another in Chase gulch, one on King flats, and another at the junction of Rine and Elk creeks, while still another is in course of erection on Beaver creek at Phœnix.——The shipments of ore each month from Dec. 1, 1902, to Dec. 1, 1903, were as follows:

Month.	Tons
December, 1902	6,540
January, 1903	7,220
February	5,400
March	5,960
April	4,620
May	5,300
June	4,700
July	5,520
August	5,120
September	4,520
October	5,000
November	3,980
Total	63,480
Shipments by wagon to Idaho Springs	15,000
Grand total	78,880

These shipments show a falling off from the previous year.

Gunnison County.

Manager Lockwood of the Brooklyn T. Co. is arranging to start his compressor on their tunnel near Crested Butte in the spring. —— D. Harris and H. B. Gillespey expect to start development on their lead and silver group in the spring. The group is in the Cement creek lime belt.

The Congress G. M. & M. Co., with principal office in Hartford, Conn., has started operations on its holdings at White Pine. G. Williams, manager, has let contracts for surface buildings on the Comstock, Jr., group at White Pine, and when this work is completed a 16x16 compressor, with 60 H. P. return tubular boiler will be set up. The workings on the Comstock consist of a tunnel in 160 feet, showing a 5-foot vein with 2-foot pay streak lying between walls of lime and quartzite, says the Pitkin Miner. The ore assays 50 ounces silver, $6 in gold, with zinc and copper. This mine is on Lake hill.

Hinsdale County.

At the Moro mine and mill, near Lake City, owned and operated by the Hanna G. M. & M. Co., operations were started this week. The ore bins at mine and mill are full, containing 1000 tons of dump ore. The stopes in the mine are ready to break down the ore. The aerial tram delivers the ore from the mine to the mill. —— The Pelican mine, 1 mile from Lake City up Henson creek, will be started up again. The company proposes to put on machine drills and run a 1000-foot development tunnel to cut the ore shoot opened in the upper workings. A tunnel 1000 feet long will give them an additional block of stoping ground 400 feet thick.

Lake County.

The total ore tonnage of the mines of Lake county for 1903 reached 1,000,000 tons of a gross value of $12,000,000. This is a larger tonnage than previously produced with smaller average values, says the Carbonate Chronicle. Against these figures the mines were able to produce at least another 200,000 tons of low-grade ores could the smelters have taken it. The following were added to the list of shipping properties during the year: Fryer Hill M. Co., with capacity of 500 tons a day; Coronado M. Co., capacity 250 tons daily; Fitz Hugh mine, capacity of 50 tons daily; Diamond mine, capacity 300 tons daily; Ollie Reed mine, 50 tons daily; Reindeer mine, 50 tons daily; Cloud City M. Co., 50 tons daily; Gilt Edge mine, 50 tons a day; and others with under 50 tons daily capacity.

Saguache County.

The Diorite M. & M. Co. has been incorporated to operate near Cochetopa by W. B. Tuttle, W. H. H. Miller and B. T. Brooks of Denver, the last named being manager. The company's property consists of the Boston, Mayflower, Vulture and Equator lodes, on which gold-bearing veins have been opened.

San Juan County.

The following shipments of ore and concentrates from mines of San Juan county for year 1903 are reported by the Silverton Standard:

Month.	Tons.
January	4,200
February	3,450
March	3,795
April	3,855
May	3,975
June	3,780
July	3,960
August	5,445
September	5,940
October	5,250
November	4,680
December	4,800
Total tons (4-5 concentrates, 1.5 ore)	53,130

The value of the output was: The Iowa-Tiger, North Star (Sultan mountain), North Star group (King Solomon mountain), Highland Mary, Brooklyn, Queen City, Silver Ledge, Negolds, Champion, Red Mountain district, Scotia mines and mills, and others in the upper Animas, Ice Lake, Little Maud, Tempest and single car shipments from twelve others (principally ore)—

*12,100 tons at $58 per ton	$ 701,800
Gold King (concentrates) 15,000 tons at $45 per ton	702,005
Silver Lake (concentrates) 18,660 tons at $51 per ton	951,660
Sunnyside (concentrates) 4,200 tons at $11 per ton	46,200
Esmeralda (ore) 2,500 tons at $60 per ton	150,000
Isolde (ore) 200 tons at $175 per ton	35,000
Amalgam and bullion from mills which by request of owners is compiled and given collectively	658,942
Total	$3,245,607

*1000 tons sent via Ouray and not computed in D. & R. G. shipments.

The output for 1902 was $3,048,170. Machinery and mine and mill building improvements for past year in county, outside of Silverton, valued at $520,000. Number of men employed in mines, mills and prospects in the county, 1360.

Summit County.

(Special Correspondence).—The Quandry Mountain M. & M. Co., owning the Monte Cristo mines at head of Blue river, 8 miles south of Breckenridge, near Hoosier pass, has its 100-ton concentrating mill nearly completed. They are putting in concentrators and steel jigs, and expect to be able to mine and mill the ore for $2.50 per ton. The ore carries considerable lead, with some gold, silver and copper. W. H. Nance is mill superintendent.

Breckenridge, Jan. 3.

Teller County.

The output of Cripple Creek district mines for 1903 is given by the Colorado Springs Gazette as follows:

	Tons.	Value.
January	59,905	$1,943,800
February	51,674	1,651,970
March	54,800	1,859,270
April	50,850	1,702,650
May	48,650	1,695,415
June	51,650	1,763,687
July	56,300	1,966,800
August	29,700	982,555
September	22,150	692,200
October	35,050	963,660
November	42,600	1,290,000
December (approximate)	42,600	1,290,000
Totals	516,079	$17,630,107

The cyanide and chlorination plants at Colorado City, Florence and in Teller county handled 432,935 tons of ore, from which was extracted $11,037,422. The average value of the ore was $25.50 a ton.

The following table gives the record of each plant:

RECORDS OF REDUCTION PLANTS.

Plants.	Tons.	Value.
United States plants	203,000	$5,008,000
Portland	63,575	2,011,350
Dorcas	33,250	1,182,900
Telluride	38,100	1,036,200
Economic	40,030	1,020,950
All Others	24,600	129,022
Total for milling ore	132,935	$11,037,422

The average value of the smelting ore was $45 per ton, and 73% of the total output was handled at the chemical process plants, leaving but 27% for the smelters.

The production by years from the beginning of the camp to date is as follows:

1891	$200,000
1892	600,000
1893	2,400,000
1894	3,600,000
1895	7,200,000
1896	8,000,000
1897	12,500,000
1898	15,000,000
1899	19,543,110
1900	20,338,300
1901	21,503,638
1902	21,177,801
1903 (approximate)	17,630,107
Total for 13 years	$149,782,856

During month of December there were shipped from the Portland mine on Battle mountain, Cripple Creek, a total of 10,667 tons of ore, says Manager Burns. There are 700 men on the payroll.

There are several Cripple Creek properties which will resume on company account this month, among which will be the Wild Horse, Deadwood, Hull City placer lease, Findley and the Isabella lease.

Manager C. Birch says he will continue development on the Ready Cash claim of the Little Johnny Co., in Pony gulch, Cripple Creek. The shaft is 125 deep. A 5-foot vein dipped out of the shaft at depth of 40 feet, and a crosscut will be run 65 feet to catch the vein. A cyanide mill will be built.——Walsh & Co., leasing on the Forest Queen, on Ironclad hill, have cut 18 inches of smelting ore in a drift run from the bottom of the shaft, which is 185 feet deep. Sinking will be resumed. —— The Wright lease on the Thompson of the Elkton Co. shipped during the month of December 2800 tons of ore, which averaged $20 per ton.

In the case of the Stratton Independence Co. of London against the executors of the estate of W. S. Stratton at Cripple Creek, claiming $6,000,000 damages for the alleged salting of the Independence mine before its sale to the English company, Judge Riner, in the United States Court at Denver, on the 5th inst., decided for the defendants.

IDAHO.

Idaho County.

(Special Correspondence).—The Rainhow Mountain G. M. Co. of Joplin, Mo., owning the Gold King group of eight claims and a fraction on east slope of Rainhow mountain, 2 miles southwest from Roosevelt, has a working tunnel being driveu by two shifts and is in 200 feet. The face of the tunnel is in ore. Surface showings indicate the ledge is 40 feet wide, which runs $4 per ton in gold. There is some silver in all of the ore which runs up to fifteen ounces per ton. There are dikes of quartz-porphyry on the claims of the company. C. Mahan is superintendent. ——The Thunder Mountain G. M. Co., L. C. Van Riper of New York owner, C. Mayen superintendent, has the Toronto group of seven claims adjoining the Gold King group to the north. It is on a dike running parallel with the Gold King dike. The ore is mainly free milling. A tunnel is being driven and is in 220 feet.

At the First National group of twelve claims, located on Middle Fork of Trap creek, 2½ miles northwest from Roosevelt, the main vein is in 10 feet wide between walls of diorite and phonolite, and runs northwest and southeast. The ore is quartz-porphyry and carries sulphides. Surface ores assay $10 gold, three ounces silver, with traces of platinum also reported. Work on the tunnel will be continued during the winter. The slope of the mountain is such that at the tunnel site 100 feet of tunnel will gain 90 feet in depth. There is mining and building timber on the property. H. P. Brown is manager.

The Duquesne Dev. Co. of Pittsburg, Pa., M. A. Rice manager, owns eight quartz and six placer claims on Placer creek, a branch of Marble creek, 18 miles south from Roosevelt. A tunnel started

to crosscut the ledge has heen driven 125 feet in diorite and has 200 feet more to go to reach the ore. The upper tunnel is in 75 feet. Assays on this lead taken from the surface gave $3 per ton gold, the width of the ore hody heing 10 to 30 feet. —— The South Dewey T. & M. Co., having a tunnel site on western slope of Thunder mountain, has the tunnel in 195 feet. Operations are suspended for the winter.

The Twentieth Century M. & Dev. Co., W. S. Culp of Cleveland, Ohio, president, has tunnel sites on Rainhow mountain, also placer claims on Monumental creek, 2 miles south from Roosevelt. The company has this season huilt a sawmill of 16,000 feet per day capacity on its ground at mouth of Botha creek. Water ditches have heen extended up Botha and Monumental creeks to furnish the mill with water for power. Work is partially suspended until spring. —— The Empress T. & M. Co. of Chicago, Ill., having a tunnel location on south side of Botha creek, west of the Monumental, 3½ miles southwest from Roosevelt, is driving its tunnel, the face of which is in diorite.

The Pittsburg T. M. Co. of Chicago, Ill., O. F. Gihhs president, has a group on Holy Terror creek slope, north of the Dewey and Sunnyside, adjoining the latter, and consisting of ten claims. About 150 feet of tunnel work has heen done. H. B. Fulton is manager. —— The Gold Standard group of seven claims adjoins the First National on the north and east. J. Tucker of Eugene, Or., manager, says development work will he continued during the winter.

Roosevelt, Jan. 1.

Lemhi County.

The Lemhi Herald says the tin discovery made 3 miles north of Salmon City is undergoing development. The ore is said to assay 10% tin, 20% lead and $4 in gold and silver. Besides this a ledge carrying cassiterite is heing opened up on Panther creek. Nickel prospects are being developed in Blackbird district by Nampa men.

Shoshone County.

The Frisco mine at Gem was hid in at sheriff's sale last week by D. M. Hyman of New York for $108,000. He is owner of a majority of the bonds which were secured hy mortgage. The mine has not been profitable in the past two years, owing to depth of workings, 2000 feet.

MICHIGAN.

The coarse system of stamping practiced at the lake mills has been in use five years and is giving satisfactory results, says the News. In coarse stamping they use mortar grates with openings larger than $\frac{3}{16}$ of an inch, which was formerly the standard. The screen mostly in use is $\frac{1}{8}$, while the revolving screens return to the head all rock over $\frac{1}{16}$. The object is to extract all copper possible before the rock is ground down to fineness of sand. Fully 50% is now taken out before the pulp reaches the first jig—under the old process the amount was 10%. This reduces the amount of water neces sary and results in saving flour copper formerly washed away with the tailings. This system increases the capacity of each head 20%, reduces the water consumption 33% and reduces loss in tailings 25%.

Houghton County.

The Isle Royale mine, near Houghton, is again on same basis as for the eleven months prior to last July, shipping from No. 2 shaft, says the News. No. 1 has been closed down until retimbered. Sixteen drills are in service and 120 men working. Three drills are drifting; remainder stoping. The most northerly point at which operations are resumed is 1500 feet north of No. 2 shaft on the fifteenth level. Extent of damage to No. 1 is as yet undecided. Jams have formed at eleventh and fourteenth levels of hurned timhers and rails from skip track. The mine will ship 500 tons to the mill daily for the present.

The new Calumet mill of the Calumet & Hecla mine of Calumet is enclosed and concentrating tables set up. One head at this mill will he hurried to completion so as to go into commission with the six in the Hecla mill. It is expected to be ready by Feb. 20th.

It is expected to have the compressor of the Champion mine at Painesdale in operation before Feb. 1. The delays in delivery of this equipment have hampered production.——The Tamarack mine, near Calumet, has also been troubled by delays in delivery of heavy machinery. The parts of the 100-drill air compressor and 1000-foot hoist are arriving. When set up, No. 5 Tamarack shaft will have equipment capable of breaking rock from over 5030 feet in vertical depth.

The Centennial M. Co., near Calumet, during last month increased its number of men at work by forty and ten additional drills have also been put in commission.

MONTANA.

Figures for that portion of the gold product of Montana which passed through the Helena assay office during the year are reported as below, compared with the output for 1902. The figures do not represent the total production of gold in the State, as they do not include the statistics from the mines of Butte nor those of the American S. & R. Co.; also, some of the producers in the State ship their product to the mint at Philadelphia, Pa., and still others ship to the assay office at Boise, Idaho, and these figures will not he available until next spring.

Counties.	1902.	1903.
Fergus	$412,317 89	$975,108 06
Lewis and Clarke	466,930 96	265,727 53
Madison	282,424 60	290,682 18
Park	279,942 76	167,404 63
Other counties of State	351,615 59	377,436 28
Total for Montana	$1,793,231 80	$2,076,358 68

Flathead County.

W. D. Wrighter, president of the Rustler M. & M. Co., operating the Snowshoe mine, near Lihhy, says the past season they have turned out seventy-five carloads of concentrates, averaging thirty tons per car. The concentrates run $60 to the ton. The mill continues in operation. At present time there is water enough in the reservoirs to keep the mill running until Feb. 1st., but a freezeup may necessitate a shut-down sooner. Concentrates are heing hauled to Lihhy depot. Wrighter says the mine has heen unwatered to the lowest level reached by their shaft, wbich is 350 feet helow the main working tunnel. They are drifting south on the vein at this level and have gone 100 feet, having done as yet no stoping from that part of the mine. All of the ore mined the past season has come from above the 200-foot level. The company proposes improvements in the mill the coming summer, to consist of additional tables and more sliming capacity, also a Huntington mill to save more of the gold values.

Jefferson County.

The Pennsylvania-Montana M. Co., operating the Hattie Ferguson mine in Cataract district, near Basin, is putting in machinery, and it is expected shipments of ore will begin Feb. 1st.

H. Riley & Co., who have leased the Berytha mine at Corhin, are shipping ore to the smelter.

The McCabe Co. is working men sinking three three-compartment shafts on its three groups between Wickes and Corbin, where they have 200 claims. The shafts are down 60 feet, and that on the Erickson group is in a body of copper ore. It is intended to sink other exploration and working shafts.

Lewis and Clarke County.

The Pittsburg & Montana Co., operating a pyritic smelter, will build a railway spur from the Northern Pacific, near Weed Siding, near Helena, to its Olson group in Greenhorn gulch.

The Big Dick M. Co., owning ten claims 4½ miles south of Helena, adjoining the Big Indian mine on the west, reports development work under way. Considerable work has already heen done on these claims. The Big Indian Co. will sink a shaft on its main lead 1000 feet deep and then run a tunnel to the houndary of the property, giving depth of 1500 feet at the end. S. L. Burbridge is manager.

Work is progressing on the Piegan group of mines near Marysvale. Development has been continuous during the year and 750 feet of tunnels, crosscuts and raises were completed. Two shifts are driving tunnel No. 4 on the vein. This tunnel is in 340 feet and will cut the ore bodies 150 feet deeper than the tunnel above. The vein in the face is 4 feet wide. The company during the year has bought the Early Bird and Norman quartz lodes and has bond and lease on three other claims adjoining. No ore has been stoped or milled. The company proposes to build a 20-stamp mill and cyanide plant in the spring.

Powell County.

W. N. Wolmsley of Philadelphia, Pa., of the Montana Reduction Co., says they are preparing to build 42 miles of railroad the coming season, running from Basin on the Great Northern to Elliston on the Northern Pacific and opening up a mining section heretofore untouched by railroad.

NEVADA.

Esmeralda County.

A. G. Bettles of Salt Lake City, Utah, of the Newhouse Co., has bought a group of claims in the Monte Cristo range, 25 miles northeast from Sodaville. These claims are said to cover a deposit of copper carhonate and oxide ores, together with a percentage of chalcopyrite. The price is reported at $125,000.

Lincoln County.

W. L. Colton of the Searchlight Gold-Copper Co. has put men to work on the company's property at Black mountain, 8 miles east of Searchlight. A 300-foot shaft will be sunk.

Lyon County.

E. Lane, superintendent of the Shaumut-Nevada G. & S. M. Co. of Fay, Lincoln county, says he is preparing with G. P. Smith, M. W. Seymour, H. H. Hunt et al. to reopen the Boston-Nevada copper mines at Yerington. There are seventeen claims in the group. The company has a leaching process to treat the low-grade ores.

Washoe County.

The production of the mines of Olinghouse camp, near Wadsworth, for 1903 is given by the Wadsworth Dispatch as follows, in hullion sent to mint:

Forlorn Hope	$ 1,300
Crown Point	800
Silp and Renegade	2,000
Cabin No. 2	18,000
Hutchinson	1,800
No. 1	1,200
No. 2	1,400
Belcher	200
Butte and Gold Center	6,700
Cabin No. 1 and Gold Ledge	3,300
Emma L	280
Standard	50
Jumper	3,000
Total	$40,030

Considerable development work was done during the year and is continuing.

NEW MEXICO.

Grant County.

C. R. Luton, manager of the Michigan-New Mexico C. Co., owning the Dacotah-Pearl group near Lordsburg, says work on the Dacotah-Pearl mines has been temporarily suspended owing to inability of the pumps to handle the water. A larger pump is being arranged for. Work on the 60-ton smelter for the company will be started Feb. 15. The foundations for the cyanide plant of the International G. M. & M. Co. at Malone have been built and the retaining walls are under way. It is expected to have the plant completed by Feb. 15. Its capacity will be twenty-five tons a day.

The construction of a 60-ton smelter in Burro mining district, 18 miles from Silver City, is proposed by B. Johnson of Beaumont, Tex., who has bought a group of mining properties in that district. W. Clayton is superintendent.

The Aberdeen M. Co., near Lordsburg, has taken out its steam stamp and substituted rolls.

Lincoln County.

J. S. Lenox of Roswell, interested in the Mescalero M. Co. on Eagle creek, says the company proposes to do considerable work on its property during the winter and spring, and expects to huild a reduction plant on the ground.

Socorro County.

At Carthage, near San Antonio station, on the Atchison, Topeka & Santa Fe Railway, there are four producing mines in operation. says the New Mexican. The area of this field as far as developed is 1000 acres; thickness of seam, 50 inches. In addition to this there is a field adjoining Valencia county, amounting to 100 square miles, with an average thickness of one coal seam of 50 inches.

OREGON.

Twenty-three new milling plants were ordered and erected in eastern Oregon during the year 1903, having 166 stamps, and roll mills with capacity equivalent to ninety-six stamps, says the Blue Mountain American. This work was distrihuted over twenty-three separate properties. The increase to the milling capacity of the district by this is ahout 1000 tons of ore daily. At the same time a 150-ton furnace smelter and 750-ton sampling mill was built at Sumpter, a 100-ton furnace and sampling mill is being put up at Homestead, and a 100-ton roasting and leaching plant is being erected at Eureka. ——During the year the deepest Oregon shaft attained an approximate deptb of 1200 feet. One large hoist is being set up, and several small ones were put in during this period.——Three important water power projects were practically completed in Sumpter district, Baker county, during the year 1903, for furnishing electrical power for mining and milling.

Baker County.

Operations will be resumed on the Orleans mine, near Sumpter, says Manager Swiggett. The raise from the working shaft to the surface, which will be the heginning of the shaft, will he first completed. They will then put in a hoist and sink on the ore shoot.

The smelter at Sumpter was blown in last week, and is reported running with satisfactory results.

A sinking plant will be put in on the Potosi group, near Greenhorn, owned hy the United Exploration Co., says Manager W. E. Hurd. The plant will be capable of going to a depth of 2000 feet and will be operated by electricity. Lost creek flows across the company's ground and estimates show it has sufficient volume, with the fall, to generate power for the sinking plant. A shaft, 160 feet deep, has been sunk hy hand, which shows a vein 30 feet wide, in which Hurd says he has a hody of milling ore. This has also heen further opened up by short drifts and crosscuts. On the Silver Crown claim of this group a second ledge has heen cut, showing 4 feet wide. An adit 110 feet long has heen run on the Silver Crown.

At the Victor mine, near Sumpter, the engines and the compressor are on the ground. Superintendent Smith says the property is ready for the development plant. Progress continues in two tunnels. In the main crosscut, 150 feet has been driven hy hand. Another adit has been driven above, having cut a vein 6 feet wide. When the power plant is in position it is intended to put two drills into the crosscut.

The Maxwell mine, Rock Creek district, is making regular shipments of concentrates, says the American. Snow in that hasin is 5 feet deep, and the Maxwell management is hauling concentrates to Haines on sleds. The haul is all down hill.

Grant County.

O. C. Wright, manager of the Blue Bird mine, and also of the Black Butte, near John Day, is resuming operations. A reorganization of the company has heen effected. A hoist will he put up in the spring, the plan being to raise to the surface from the tunnel level, a distance of 80 feet, and in the spring sink the shaft.

The Magnolia mine, near Granite, has been honded to G. J. Barrett of Granite, together with the Golden Star claim, hetween the Magnolia and the Independence mines. Development work will be started next week. The bond includes the seven claims and fraction of the Magnolia group, the Golden Star, the milling equipment of the Magnolia, and houses, machinery, etc., on the group. There are 3000 feet of development on the Magnolia proper.

SOUTH DAKOTA.

Lawrence County.

(Special Correspondeuce).—The Clover Leaf G. M. Co. (the Uncle Sam mine) report having opened up tbe ledge on the 700-foot level in a body of good ore. O. B. Amsden is superintendent.

Roubaix, Jan. 2.

Excavation work has been started by the Homestake M. Co. for enlarging its cyanide mill at Lead, to double the capacity of the plant. This is necessitated by the addition of 100 stamps to the Amicus mill of the company. This cyanide plant will, when enlarged, have capacity for handling 3000 tons of tailings daily.

The Lundberg-Dorr cyanide plant at Terry is in operation. It has one Chilian mill with capacity of eighty tons of ore per day. Some custom ore will be handled in addition to the company's ore. The Northwestern Railway Co. has built a side track to the mill.

Pennington County.

Superintendent Croft, of the Redfern G. M. Co., has resumed work with a few men and is sinking a shaft on the company's ground, north of Hill City.

UTAH.

Beaver County.

The Milford Times, speaking of the Majestic C. Co. smelter's run, says the plant was not worked at full capacity until towards the end of the run, when lt handled over 200 tons of ore per day, the average for the entire run baving been 170 tons. Following are the figures: Smelter in operation, 40 days; total expense, $35,000; value of matte produced, $62,500; copper produced, 246 tons; average contents of ores—copper, 5.1%; silver, 3.8 ounces; gold, .06 ounce; net cost of smelting, $3.75 per ton.

The Copper Mountain group, in Beaver Lake district, has been taken over under lease and bond by W. J. Bowring & Co. The bond runs for two years at $125,000. Men will be put to work this week. The incline shaft, which is 450 feet deep, will be straightened and continued down to develop the sulphide ores that have been struck. Their plans also include building a leaching plant to treat the oxidized ores of the upper workings. The vein, 20 feet wide, is said to average 5% copper. The property is equipped with a gasoline hoist, blacksmith shop, boarding house, etc.

W. Harrison has taken over the Wasatch King group, in Beaver Lake district, near Milford, and will develop it. ——The Lenora M. Co., which bought the Lenora group, in Star district, near Milford, has been incorporated at Salt Lake City by M. L. and W. J. Burns, P. C. Evans, B. H. Smith, and I. D. Carpenter, the last named heing manager.

Box Elder County.

The Giant Copper Queen M. Co. bas been incorporated at Salt Lake City by C. E. Dugger, B. Rose and M. H. Redding. The company owns the Copper

Queen group of claims in Box Elder county.

Grand County.

Manager W. R. Wheat of the Grouse Mountain M. Co.'s mines, in Miners' basin, near Basin, is arranging to build a cyanide plant, and as soon as practicable in the spring will begin breaking ground for the foundation. The mill will be below the Thompson stamp mill and convenient to all the mines of the district. The plant will have a daily capacity of fifty tons at the start.

Juab County.

The South Swansea mine of Tintic, near Eureka, which was temporarily closed down, resumed operations last week with an additional shift.

Superintendent Turner has put in a hoist at the top of the incline shaft at the Yankee mine, near Eureka, and is putting the mine in shape for an increased output. He has bought horses and wagons and hereafter the company will do its own hauling of ores.

The Tintic Miner gives the shipments from Tintic district for the month of December:

	Cars of Ore.
Bullion-Beck	20
Carisa	27
Centennial-Eureka	206
Gemini	25
Grand Central	102
Lower Mammoth	51
Swansea	16
South Swansea	13
Tetro	14
Yankee Con	27
Five other mines, a total of	24

IRON ORES.

	Cars.
Dragon Iron Mine	30

CONCENTRATES.

May Day	3

During the year 1903 there were 6480 cars containing 194,400 tons of ore shipped from Tintic district.

Salt Lake County.

Fires were started last week in the roasters of the Yampa smelters, at Bingham, and the furnaces are being blown in.

Superintendent Rumbaugh of the Galey & Guffey Oil Co. says he expects to have the derricks built ready to begin drilling for oil near Farmington, on shore of Great Salt Lake, by Feb. 1.

San Pete County.

Development work is reported progressing by the Silver Cave M. Co., near Ephraim. The main working tunnel has been driven to 270 feet and an 18-inch shoot of ore is opened, giving assays of $5 gold and 15% copper.

Summit County.

The ore output for 1903 of the mines of Park City was:

Mine.	Tons.
Daly-West	83,208
Silver King	48,672
Ontario	2,308
Daly-Judge	625
Comstock	440
California	164
Crescent	157
Scotch Chief	99
Creole	90
Barnes Bros.	166
Sundries	433
Total	136,362

The Kearns-Keith mill at Park City is being run at its full capacity with one shift and is averaging sixty tons per day. Shipments of concentrates have begun. The road to the mill is in a bad condition, says Foreman Kescol.

The Cougar G. & S. M. Co. has been incorporated at Park City, to develop holdings on the Smith & Morehouse Fork of the Weber river, 22 miles east of Park City. The ledge carries gold and silver values. The officers of the company are R. W. McDonald, G. F. and A. M. Martin.

At the King Con. mine, at Park City, the sinking pump is in operation. The shaft is down 690 feet, and when the 700-foot level is reached a station will be cut and a heavier pump put in, says Superintendent Keetly.

Tooele County.

The Sacramento G. M. Co., at Mercur, is shipping quicksilver to New York, sending out last week 350 flasks, on which a value of $15,050 was placed. The retorts are reducing 3000 pounds of mercurial gold ore daily.

WASHINGTON.

Ferry County.

(Special Correspondence).—During 1903 46,000 tons of ore have been shipped to smelters with profit over cost of mining, transportation and smelter charges. The mines have been undergoing systematic development during this period.

The output of Republic mines for 1903 was, approximately:

Mines.	Tons.
Quilp	27,000
California	1,000
Lone Pine	4,500
Mountain Lion	10,000
North San Poil	560
Knob Hill	930
San Poil	180
Trade Dollar	460
Tom Thumb	27
Morning Glory	300
Little Cove	270
Zala M	900
American Flag	60

Men are driving the tunnel on the Belcher. The Wauconda is again in operation. The Golden Eagle is sinking and is down 300 feet.

Republic, Jan. 3.

Work is expected to be resumed on the Tom Thumb mine at Republic, owned by the Tom Thumb M. Co. of Walla Walla. It is proposed to build a mill and to resume development by Feb. 1.

C. T. Porter, superintendent of the Golden Lion-Little Four M. Co., has resumed work on the mine at Republic. Last summer a body of quartz was cut on the west side of Granite creek and a shaft sunk. The company will sink a prospecting shaft for 100 feet on the east side of the creek to catch the vein on its dip. The Golden Lion tunnel, which is in several hundred feet eastward from the east side of the creek, will be cleaned out and retimbered.

At the Mountain Lion mine at Republic, a plant is being built for treatment of their ores by electro-cyanide process. The dynamos and other electrical equipment, as well as the agitator, are all on the ground. The agitator will be 16 feet in diameter, with 9 feet vertical sides, and 8 feet on the slope of the conical bottom. The pump well will be 2 feet in diameter. It is intended to crush the ore to eighty mesh, first reducing it with twenty stamps and then crushing to the required fineness with four Huntington mills. From the latter the pulp will be automatically conveyed to a series of five storage tanks and thence to the agitator. The agitator will be charged four times every twenty-four hours, requiring six hours' agitation for an extraction of 80% of the gold and silver contents of the ore. Each charge will consist of forty tons of ore, and sixty tons of KCN solution. The gold and silver dissolved by the cyanide will be deposited on copper plates by electric current and the pulp discharged into settling tanks. From the settling tanks the solution will be decanted into a sump tank and thence pumped to the battery tank to be reused. The tailings will be sluiced into launders and delivered by gravity to a tailings pit.

Stevens County.

The United States Copper-Gold Co. is preparing to develop its holdings near Chewelah. A 200-foot tunnel will be run on the vein.——J. B. Tuttle, superintendent of the King mine, says he has struck a body of ore on the lower level that carries values in copper and silver.

WYOMING.

State Coal Mine Inspector N. Young of the Eastern district has completed his report for the year 1903, but no returns have yet been received from Inspector Bradbury of the Western district. Young's report shows as follows:

Mine—	Tons Mined.	Men employed.
Dietz mines, near Sheridan	457,493	500
Cambria	419,586	665
Glenrock	90,543	75
Coal Creek	14,000	25
Black Hills mine at Alladin	10,468	35
Casper, Thermopolis, Douglas, Meeteetse, Sheridan and Cody mines, estimated	30,000	50
Totals	1,022,090	1,350

It is estimated the total output of coal for the entire State will be 4,500,000 tons.

Carbon County.

A flow of oil is reported struck last week east of Rawlins by J. H. Anderson and N. Johnson. Drilling has been going on in the Fort Steele district, 16 miles east of Rawlins, for some time. The discovery is said to have been made on land included in the railroad grant.

FOREIGN.

AFRICA.

Cape Colony.

The annual report of the De Beers Con. Mines, Ltd., operating the diamond mines at Kimberly, for the year ending June 30, 1903, includes a summary of loss in connection with the South African war. The total was £272,904. It charged the imperial government £75,477 for expenditures in connection with the siege of Kimberly, of which only £50,836 was allowed. There were direct losses of £147,395, for which no charge was made to the government, besides other losses. Among other charges were those for putting up barbed wire fences, building forts, digging trenches, supplying horses, oxen and mules, making shells and providing other things and performing acts which show that the De Beers was an active party in prosecuting the war. One item shows that £41,286 cash wages was paid to non-combatants, white and black, for work on town roads to enable them to keep their families from starving. The company bore this expense.

AUSTRALIA.

Western Australia.

The annual report of the Lake View Consols, Ltd., at Kalgoorlie, for the year ending June 30, 1903, has been issued, shewing the total expenditure on buildings, plant and mine development amounted to £575,202. The manager's report shows a further reduction in working costs. The average Australian working costs per ton of ore treated, including royalty, but excluding expenditure on development, buildings and plant, for the last three years, have been as follows: 1901, £2 16s 8d; 1902, £2 9s 5d; 1903, £1 13s 11d. The tonnage of ore reserves has been increased during the year. This increase, however, has been accompanied by a fall in the average value per ton. In addition to the stated reserves, it is estimated there is another year's supply of ore of a lower grade between the 1000-foot and 1200-foot levels not yet sufficiently developed to be measured. In view of the reduced average value of the reserves and the continual increase in the proved quantity of low-grade ore, it has been decided to improve and increase the equipment to obtain the largest possible profit from this low-grade ore. The most important of the renewals and improvements consist of installation of electric power for a large part of the machinery now driven by steam, rebuilding and improvement of the old 50-stamp battery, introduction of a belt conveyor for residues, introduction of self-dumping skips, putting in condensers in connection with the new plant, replacing present condensing apparatus and placing pumps or other machinery to take the place of the tailings wheel. This, it is expected, will involve expenditure of £25,000, which, it is thought, will be regained in increased economy within the first eighteen months. As soon as these alterations are sufficiently advanced, the whole battery of seventy-five stamps will be worked. Ore bodies recently located in the lower levels have been sparingly included in the estimated reserves. Development in these ore bodies is slow, on account of their great distance from the main shaft. For economy, the levels are only opened at intervals of 200 feet, the levels in every case being driven to the ore bodies and connected through and ventilated by raises and winzes before anything but necessary exploratory work is done.

BRITISH COLUMBIA.

Cassiar District.

J. Stables of Atlin reports locating near the Tooya river a deposit of coal. He says the coal is bituminous and lies between sandstone. Access to the section is not difficult, it being only 10 miles from the Dease lake trail and 40 miles from Telegraph creek.

East Kootenay District.

The Laborers' M. Co. smelter was blown in last week at Golden.

Rossland District.

The Le Roi mine at Rossland is producing from its 1350-foot workings, the deepest level opened up on a practical scale in Rossland camp, says Manager Parrish. Shipments are being sent out regularly.

Slocan District.

Manager Zwickey of the Rambler mine, in McGuigan basin, says they shipped 2500 tons of ore the past year, and the mine is in shape to double that amount in 1904.——The Payne mine at Sandon is receiving 500 tons of coal per month. —— The Washington mine is working under the contract system.

The output of Slocan district for 1903 is the lowest of any year yet, says the Rossland Miner, being 14,000 tons of galena and 2000 tons of zinc, about 50% only of its normal shipment. The reason for the small output is partly due to the low price of silver and lead which prevailed the forepart of the year, coupled with the fact that four of the largest shippers have been curtailing their output on account of lawsuits. The production of zinc this year has marked a new industry for the district. Manager Garde of the Payne mine built a zinc magnetic separator and roaster. It handles twenty tons per day, raising the percentage of the zinc to 60% after it has been concentrated. It is thought the coming year other similar plants will be erected. What is needed in the province is a zinc smelter, which would save the freight of $11 per ton now paid to the United States.——There have been 500 men working in the mines adjacent to Sandon. Considerable leasing has been done.

The Payne zinc plant at Sandon is working successfully turning out ten to twelve tons daily of zinc concentrates. The grade of the magnetized concentrates is now higher than when the plant first started up, the increase being from 42.43% to 57.58%. There are between 1000 and 1300 tons on hand at the mill concentrated, and awaiting magnetization, besides a large tonnage at the mine. The electric process followed at the Payne is as follows: The 42% product is charged, after it has been through the concentrator, into a combination drying and roasting furnace, whereby the spathic iron associated with the zinc is changed into a magnetic product. After cooling the roasted ore is sized on vibrating screens and passed over a magnetic separating machine, the iron being retained. The whole plant is arranged to work automatically.

FRANCE.

Auriferous depesits are reported found in the antimony mines at Bas Coudray and Haut Coudray, in the Department of Mayenne, by M. Herrenschmidt, a French engineer. He says the deposits, extending several miles in quartz strata at 20 metres under the surface, give sixty grammes (1.92 ounces) a ton in gold values.

INDIA.

The output of the gold mines of India for 1903 to Dec. 1, as compared with 1902, was as follows:

	1903. Ozs.	1902. Ozs.
January	48,080	41,612
February	46,268	40,053
March	48,327	41,575
April	48,271	38,329
May	48,628	28,003
June	48,980	37,466
July	50,571	43,847
August	50,286	49,628
September	51,352	49,420
October	52,274	47,858
November	56,533	48332
December		48,078
Totals	550,120	514,291

MEXICO.

President Diaz, in his last message to Congress, shows the mining industry continues to prosper in spite of the depreciation and fluctuation of silver, which is the chief product. During the last fiscal year 4132 title deeds to mining properties were issued, embracing 61,396 hectares, which is an increase of 524 title deeds and 736 hectares as compared with the previous year. The exploitation of other ores than those containing gold, silver, lead, copper and iron is being undertaken, including cobalt, nickel, tin, bismuth and antimony. Referring to antimony, the treatment of 5357 tons of ore yielding 2159 tons of antimony in the Wadley smelter at San Luis Potosi is mentioned.

Chihuahua.

At Candemania, J. Rival is working a silver mine. Ocampo (Jesus Maria) and the neighboring mines of Sahuayacan, Concheno, Pinos Altos, etc., sections, are shipping $100,000 worth of bullion per month, says the Chihuahua Enterprise. Plans are being drawn for a 40-stamp mill for Dios de Guie mine.

At the Sangre de Cristo group, in Arteaga district, 28 miles east of Chinipas, owned and operated by the Guazapares M. & M. Co., development consists of one single-compartment shaft, down 880 feet, two tunnels driven a total of 1672 feet, with crosscuts, drifts, etc., a total of 1780 feet. Equipment consists of a roll mill, one hoist, two engines, four hoilers, an electric generator for lighting mine, mill and camp, one air compressor and a 35-ton-per-day hyposulphite of sodium leaching plant. The company proposes putting in an aerial tramway from the mine to the mill, a distance of 1900 feet, the angle of inclination being 8°, says Manager J. R. Harbottle.

At the San Francisco and Dolores mines, owned and operated by the Naica M. Co., 16 miles west from Concho station on the Mexican Central railroad in the Camargo district, the ore is said to carry silver, lead and gold, averaging $40 per ton. Development consists of three vertical two-compartment shafts, down a total of 662 feet, two tunnels driven a total of 769 feet, and from 150 to 200 feet of crosscuts, drifts, etc. They have a gasoline hoist. The company proposes putting in an additional 40 H. P. gasoline hoist, power drills, air compressor and one boiler. Work is progressing, says Superintendent J. E. Garrett.

Durango.

It is reported the Quebradilla mines of Nombre de Dios will resume operations this month. The mines have been shut down for six months, and operations were stopped in the development stage. They are owned by M. Damm of Mexico City, and Detroit, Mich., men.

Mexico.

At El Oro the Victoria y Anexas, three-compartment vertical shaft is down to the second level, or 403 feet, and crosscutting to the east started. The east crosscut on the first, or 305-foot level, is in 15 meters, and driving is going ahead. The west crosscut on the first level has been driven to the company's boundary line; and, as nothing was cut by this, and as the veins that cut the property to the west of the

shaft dip out of the property on this side, the company will confine its work to the east of the present shaft.

The Esperanza mine at El Oro is equipped with two underground ore bins, each having a capacity of 2700 tons, and each equipped with a 13x24-inch Blake type rock crusher operated by a 40 H. P. direct current 500-volt motor. The ore bins are built one at each shaft, and the ore is run from them through the rock crushers before going to the 120-stamp mill and the thirteen Huntington mills. The two shafts, the main or south shaft and the north shaft are 448 meters apart, being connected by underground workings.

At El Oro the El Oro mine cyanide plant equipment consists of ten sand-settling tanks, twenty-four slime-settling tanks, six preliminary slimes-treatment tanks, five final slimes-treatment tanks, fifty-four sand-treatment tanks, three storage tanks, three gold-solution tanks, three filter tanks, twelve wooden precipitating boxes 18x2x2 feet, nine steel precipitation boxes 23x30x30 inches, each of the twenty-one boxes having nine compartments and one sump tank. Three strengths of solution of KCN are used.

El Oro mine at El Oro is being developed through four shafts and one tunnel, besides crosscuts, drifts, etc. The main shaft, three-compartment incline, is down 745 feet; the north, two-compartment vertical, is down 630 feet; the Somera, three-compartment vertical, is down 1050 feet, and the Providencia, the first shaft sunk in El Oro district, two-compartment vertical, is down 650 feet. The San Juan tunnel (through which the water from the workings that is lifted by means of the Cornish pump through the Providencia shaft is conveyed to a tank at the foot of the hill) is 1675 feet in length; from the tank the water is pumped to the main plant and used in the mills, boilers, and for cyanidation. Progress is being made on the foundations for the 100-stamp mill.

Work is progressing on the Playedes mine, 1 mile south of El Oro. A three-compartment vertical shaft is going down, and equipment consists of engine, 30-light electric generator, air compressor, boilers, and double hoist, says Superintendent N. F. Morton.

Hidalgo.

El Almaden and La Providencia properties, consisting of 100 pertenencias, 10 kilometers east by south from Tulancingo, in district of same name, have been bonded by J. M. Erskine of the City of Mexico for thirteen months for $100,000 gold. These mines have been worked by Mexican methods for twenty years, and the total development work—tunnels, drifts and one shaft—amounts to 1500 feet. This work was done by the natives in search of cinnabar, of which there is said to be a deposit on the group, and, in sinking the shaft, ore carrying gold and silver was cut.

J. M. Erskine of El Paso, Tex., is reported to have bought El Almaden mines, 2 miles from Ahuechuetes station and near Tulancingo, for $100,000 gold. The mines were opened twenty years ago and heen worked only intermittently. The ores are of gold and silver. Cinnabar is said to occur on the property. Erskine has made other locations amounting to eighty pertenencias, in addition to the original 100. Timher is at hand. The ore is said to he adapted to milling and a stamp mill is proposed.

Sonora.

W. E. Pomeroy, superintendent of the Yaqui C. Co. properties in Sahuaripa district, says it is intention of the company to build a 1000-ton smelter at Campo Santo Nino in the spring.

At San Ricardo G. Charters, manager for the American-Mexican M. & Dev. Co., reports work progressing. G. Phillips is superintendent. Machinery for a 20-stamp mill is on the ground and five stamps are set up and in operation. The water from the mine is sufficient to run the five stamps. To run more they will pump water from the San Miguel river, distance of 1¼ mile. A pipe line and pumping station will ho put in. The American-Mexican M. & Dev. Co. has a group of seven properties, embracing sixty pertenencias of ground, which is said to include seven gold hearing ledges. They show ancient workings.

PHILIPPINE ISLANDS.

J. D. Hartwell, writing from Manila, says he is building a 3-stamp gold mill for his claims in Benguot province. The oro is free milling, avoraging on tho surface $20 per ton in gold.

TASMANIA.

The Mount Lyell Mining & Railway Co., operating at Mount Lyell, reports for Nov. 12 to Dec. 9, inclusive, a total quantity of 26,727 tons of ore treated, heing 20,167 tons from the Mount Lyell mine and 6560 tons from the North Mount Lyell mine. In addition to this there were treated 249 tons of metal-bearing fluxes. The converters produced during same period 538 tons of blister copper, containing: Copper, 531 tons; silver, 58,644 ounces; gold, 1208 ounces. Reduced tonnage due to accumulation of ore being made to tide over any cessation of mining operations during the Christmas holidays.

Personal.

G. G. MERRICK, of Denver, Colo., is in New York on business.

EMIL MELZER has returned from San Fraucisco, Cal., to Sumpter, Or.

E. J. MORRISON of Lewistown, Mont., is in New York on mining business.

W. I. HUPP of Folsom, Cal., is in San Francisco, Cal., on mining business.

J. S. CUNNINGHAM, JR., of Salt Lake City, Utah, is in San Francisco, Cal.

H. DOBSON, interested in tin mines near Teller, Alaska, is in San Francisco, Cal.

H. K. WHEELER of Los Angeles, Cal., is examining mining property in southern Nevada.

J. W. TREPP of Pittsburg, Pa., interested in California miues, is in San Francisco, Cal.

C. C. FIFE of Los Angeles, Cal., interested in Nevada mines, is in San Francisco, Cal.

E. ENGEL is superintendent of the Bismarck and Ida Florence mines, near Keystone, S. D.

DR. O. B. DAWSON of New York is in La Cananea, en route to New York, via Denver, Colo.

W. F. COPELAND of Alameda, Cal., is in El Dorado county, Cal., making mine examinations.

M. W. HOYLE bas returned to Breckenridge, Colo., from New York and other Eastern cities.

E. COLLINS is manager of the Combination group of mines at Goldfield, near Tonopah, Nev.

JOHN LAWLER, a mine owner of Prescott, Ariz., is in San Francisco, Cal., on mining business.

W. H. CHILD of Salt Lake City, Utab, of the Sheba M. Co., is in tbe East on mining business.

H. CALVIN is superintendent of tbe Bamberger-DeLamar mines, at DeLamar, Lincoln county, Nev.

W. H. NANCE is mill superintendent of the Quandary Mountain M. & M. Co., near Breckenridge, Colo.

J. F. WATERHOUSE of the Etbel mine, at Gaston, Nevada county, Cal., is in the East on mining business.

S. U. WATSON, who has heen building a cyanide mill near Chloride, Ariz., has returned to Denver, Colo.

P. P. BUSH, Western manager of the Canton Steel Co., has returned to Denver, Colo., from Canton, O.

L. H. STEVENS, manager of the Batopilas mines at Batopilas, Chihuahua, Mexico, is in Washington, D. C.

G. L. MOATS, manager of the Four Metals M. Co., returned to Salt Lake City, Utah, from a trip East.

ISAAC COPELAND of Alameda. Cal., bas gone to Columhia, Tuolumne county, Cal., to make mine examinations.

R. E. TOWNSEND, operating mines at Gilt Edge, Fergus county, Mont., is in New York on mining business.

C. A. HOLLAND, manager of the Altadena mine, near Columhia, Tuolumne county, Cal., is in Boston, Mass.

N. S. CLARKE, representing the Northwestern S. & R. Co. of Crofton, B. C., has returned from Hermosillo, Mexico.

A. J. MCCONE of the firm of Harron, Rickard & McCone has returned to San Francisco, Cal., from Tonopah, Nev.

W. W. MERRIAM AND D. GOODALE, interested in Siskiyou county, Cal., mines, are in San Francisco, Cal., from Etna.

W. MCCORNICK returned to Salt Lake City, Utah, last week from the placers of the Siborian Exploration Co. in Siheria.

K. M. JACKSON has returned to San Francisco, Cal., from a visit to mines at Tonopah, Nev., in which he is interested.

J. C. BROOKS of Chihuahua City, Mexico, is superintendent of the Braden mines at Cerro Almaloya, Chihuahua Mexico.

G. H. DERN, manager of the Con. Mercur G. M. Co. of Mercur, Utah, returned to Salt Lake City, Utah, last week from a trip East.

J. W. VAN METER of the Van Meter-Boss Oil Concentrating Co. has gone from San Francisco, Cal., to Los Angeles, Cal., on business.

L. W. ALDRICH, Denver, Colo., has returned there from Old Mexico, wbere he bas been for several weeks looking after mining interests.

W. E. HURD of Portland, Or., manager of tbe United Exploration Co., operating in tbe Greenhorn mountains, Baker county, Or., is in the East on business.

F. W. MITCHELL returned to Salt Lake City, Utah, last week, from California, from the properties of the Shasta G. & C. M. Co., of which he is superintendent.

CHAS. THOMAS of Fairbanks, Morse & Co., who has been installing a complete mine and mill plant at Sumpter, Or., has returned, via Portland and San Francisco.

W. L. WILSON, secretary of the Thunder Mountain Gold King mine, has returned to Denver, Colo., from New York, where he has been on company business.

COLIN MCINTOSH, for tbe past three years manager of the Big Indian M. Co., near Helena, Mont., bas accepted a position with a company operating in South Africa.

R. SWAIN, for the past three years representative of the Willfley concentrator in Arizona and Mexico, with headquarters in El Paso, Texas, is now located in Denver, Colo.

C. J. BUSH, assistant Western manager of the Canton Steel Co., with office in Denver, Colo., has resigned to accept a position with tbe Crucible Steel Co. of America.

A. H. STOW has removed from Hunter to Switchback, W. Va., where he has engineering charge of the six Elkhorn plants, of which J. E. Jones is general manager.

W. E. THORNE returned to San Francisco, Cal., from the mines of Butte county, Cal., for the State Mining Bureau, and has gone to Denver, Colo., in which State be will make mine examinations.

W. HENDERSON, formerly manager of the Queen Margaret G. M. Co.'s mines at Bulong and the Gippsland leases at Vasperton, Western Australia, is manager of the Princess Royal Central mines at Norseman, Western Australia.

M. D. DRAPER, lately superintendent of the Town Topics M. Co., Central City, Colo., bas gone to Hedges, Cal., to assume charge of the mines operated by the American Exploration Co. of Colorado Springs, Colo.

S. A. PARNALL is suporintendent of the Calumet & Arizona mine, near Bisbee, Ariz., vice L. L. Merrill. Mr. Parnall will also have charge of work at the Calumet & Pittshurg, Lake Superior & Pittsburg and tbe Pittsburg & Dulutb properties which are under management of Lake Superior, Mich., interests.

Trade Treatises.

THE Smooth-On Manufacturing Co. of Jersey City, N. J., have issued a booklet telling ahout Smooth-On, its different combinations, and their applications. The latest combination is Smooth-On with ruhher, which tbey say makes a sbeet packing tbat will withstand high temperatures and pressures. The company will he pleased to send the catalogue to anyone asking for it. Either the home office or the Western Repair & Supply Co., 61-63 Steuart street, San Francisco, Cal.

The second edition of Catalogue No. 5, "Hydraulic Mining Machinery," issued hy Harron, Rickard & McCone, 21-23 Fremont St., San Francisco, Cal., is of commensurate value with their series of similar treatises on gold mills, mine and mill supplies, etc. It describes and illustrates the Camphell hydraulic gravel elevator, douhle-jointed ball-bearing giants, water gates, doflectors, etc., and gives several valuable tahles and tabulated information—tbe whole in compact form. A copy will he mailed to any designated address.

Dividends.

North Star M. Co., California, $125,000; Jan. 1.

Bunker Hill & Sullivan M. & C. Co., Idaho, $30,000; Jan 5.

Obituary.

J. POWNING, a pioneer miner of Nevada county, Cal., and on the Comstock lode in Nevada, died at Nevada City, Cal., on the 5th inst. Deceased was a native of England.

J. MUSTO, a pioneer miner of Calaveras county, Cal., and later an importer of Carrara marble, died at San Francisco, Cal., on the 3rd inst. Deceased was a native of Italy, 74 years of age. He is survived by a widow, four daughters and two sons.

JACOB HOUGHTON of Detroit, Mich., formerly managing director of the Iron Silver M. Co. of Leadville, Colo., died in Detroit, Mich., on the 29th ult. Deceased was born in Fredonia, N. Y., in 1837, and was educated at the University of Michigan as a civil and mining engineer. His elder brother, Douglas Houghton, was a geologist and made the first geological survey of tbe copper and iron district of the upper peninsula of Michigan in 1844. Deceased was division engineer in charge of the Michigan Central Railroad from Jackson, Mich., to Detroit, and was also engineer in charge of the Detroit city water works. After completion of this work he engaged in mining in the Lake Superior region and was for several years general manager of the Iron & Copper Co. In 1872 he moved to tbe iron districts of Marquette county and became manager of the Michigan Iron Co. In 1878 he removed to Colorado and took charge of tbe Moose mine in Park county, and later became interested in the Iron Silver Co. of Leadville. At his death he owned interests in California gulch, Leadville, consisting of the Garden City, Star of the West and Satellite properties (tbe Houghton M. Co.), and was also interested in Lake Superior iron properties. He leaves two sons and two daughters.

Commercial Paragraphs.

R. D. HUNTER, manager Denver, Colo., office of the Sullivan Macbinery Co., bas moved his office from 431 Seventeenth St. to 1748 Broadway, where be will bave a room 25x100 feet, with basement. The office is next door to the Metropole Hotel and across the street from the Brown Palace.

THE Loomis-Pettibone Gas Macbinery Co. has been merged with the Holthoff Machinery Co. of Milwaukee, Wis., under the new corporate name of Power & Mining Machinery Co. They are making extensive improvements and additions to the Milwaukee plant to supply the American Crossley gas engines, Loomis-Pettibone gas apparatus and Holthoff mining machinery. They will continue, under Mr. Holthoff's personal supervision, the manufacture of mining, smelting and milling plants and machinery.

THE W. S. Tyler Co. of Cleveland, Ohio, manufacturers of wire cloth, have completed their new power plant. Tbe boiler house is 70x37 feet and contains three 400 H. P. water-tube boilers, one 1500 H. P. water heater and two boiler feed pumps. The fires are operated hy the induced-draft system, coal handling apparatus conveying the coal from the cars to the coal hunkers of 800-ton capacity. From there the coal passes through the weighing machine to coal hoppers at the front of the boilers and is burned on cbain grates. The engine room is 47x48 feet, finished inside with red tile floor and marble white glazed brick sides. A 500 H. P. Allis-Chalmers Corliss single-cylinder horizontal engine is direct-connocted to a 300 K. W. 110-volt generator. Thero is also an 800 H. P. vertical compound Corliss engine, direct-connected to a 500 K. W. 110-volt generator. These improvements and additions were made necessary by the constantly increasing business of this concern. All the machines used in the manufacture of wire cloth are made by the company in their own shops, and, with the equipment now installed, they will he ahle to handle their growing business.

Books Received.

"Reinforced Concrete" is the title of a volume on this important and comparatively new subject, by Armand Considere. Concreto as a structural matcrial is valuahle and has been used for ages. No other material except solid masonry will endure tho ravages of time as well. In modern engineering practice concrete is

being built reinforced with steel. This material has a very wide range of application in building, and these are fully set forth and explained in the book. It treats of its bonding, tensile resistance and compressive resistance. The volume will be valuable in the hands of engineers employing reinforced concrete. 188 pages. Price $2. McGraw Publishing Co., 114 Liberty St., New York.

"American Meter Practice," by Lyman C. Reed, is a new treatise devoted to meters used in the measurement of electrical energy consumed. It treats of the various types of electrical meter, and is illustrated with half-tones and engravings. The volume is interesting to both the technical and non-technical reader, and to the latter, particularly, that chapter entitled, "How to Read a Meter." 196 pages. Price $2. The McGraw Publishing Co., 114 Liberty St., New York City.

Latest Market Reports.

SAN FRANCISCO, January 8, 1904.

METALS.

SILVER.—Por oz., Troy: London, 27¼d (standard ounce, 925 fine); New York, bar silver, 57¾c, refined (1000 fine); San Francisco, 57¾c; Mexican dollars, 43@45c San Francisco, 43¼c New York.

Within the week silver has advanced nearly 2c per ounce, but no particular significance can be attached to it.

COPPER. — Now York: Standard, $12.37½; Lake, 1 to 3 casks, $12.37½; Electrolytic, 1 to 3 casks, $12.25; Casting, 1 to 3 casks, $12.12½; San Francisco: $15.00. Mill copper plates, $17.00; bars, 18@24c. London: £58 2s 6d spot per ton.

No material change is noted in the copper market, except a slight advance in London. It is said that the foreign buyers are about to stock up for the season and an advance in price is anticipated. It is said there is no considerable surplus stock on hand in this country, and stocks in consumers' hands are small.

LEAD. — New York, $4.37½; Salt Lake City, $3.50; St. Louis, $4.00; San Francisco, $4.50, carload lots; 4¾c 1000 to 4000 lbs.; pipe 6½, sheet 7, bar 5¾c; pig, $4.75. London: £11 7s 6d ₱ long ton.

SPELTER.—New York, $5.20; St. Louis, $5.10; London, £21 15s ₱ ton; San Francisco, ton lots, 6¾c; 100-lb. lots, 7c.

TIN.—New York, pig, $28.50 @ 29.00; San Francisco, ton lots, 31c; 500 lbs., 31½c; 200 lbs., 32c; less, 32½c; bar tin, ₱ lb., 35@37½c. London, £130 12s 6d.

PLATINUM. — San Francisco, crude, $18.00 ₱ oz.; New York, ingot, $19.00 ₱ Troy oz. Platinum ware, 75 @ 82c ₱ gram.

QUICKSILVER. — New York, $46.50@47.00, large lots; London, £8 7s 6d; San Francisco, local, $44@44.50 ₱ flask of 76½ lbs.; Denver, $48.00. Export, $42.00@42.50.

BABBITT METAL.—San Francisco, No. 1, 10c; No. 2, 7c; No. 3, 6½c; extra, 17½c; genuine, 31½c; Eclipse, 35c.

SOLDER. — Half-and-half, 100-lb. lots, 19.20c; San Francisco, Plumbers', 100-lb. lots, 16.80c.

ZINC.—Metallic, chemically pure, ₱ lb., 50c; dust, ₱ lb., 10c; sulphate, ₱ lb., .04c.

NICKEL.—New York, 50@60c ₱ lb.; ton lots, 40@47c.

ALUMINUM.—New York, No. 1, 99% pure ingots, 35c; No. 2, 90%, 30@34c.

LUMBER. — (Retail): Pine, ordinary sizes, $24.00@25.00; extra sizes higher; redwood, $28.00@30.00; lath, 4 feet, $4.50 @5.00; pickets, $21.00; sbingles, $2.50 for No. 1 and $2.25 for No. 2; shakes, $13.50 for split and $15.00 for sawed; rustic, $28.00 @35.00.

NAILS.—Per keg (list prices): No. 20d to 60d, Wire, $3.35; Cut, $3.55; 10d to 16d, Wire, $3.45; Cut, $3.35; 8d Wire, $3.50; Cut, $3.50; 6d and 7d, Wire, $3.60; Cut, $3.60; 4 and 5d, Wire, $3.70; Cut, $3.70; 3d, Wire, $3.85; Cut, $3.85; 2d, Wire, $4.10; Cut, $4.10. Special rates for carload lots.

LIME.—Santa Cruz, $1.60 country, $1.75 city ₱ bbl.

CEMENT.—Imported, $2.25@2.50 ₱ bbl.; California carload lots, $2.00 f. o. b. at works; small lots, $2.25 ₱ bbl. in sacks, 4 sacks to bbl.

STRUCTURAL MATERIALS.

IRON.—Pittsburg, Bessemer pig, $14.00 @14.35; gray forge, $12.35; San Francisco, bar, 3c ₱ lb., 3¼c in small quantities.

STEEL. — Bessemer billets, Pittsburg, $23.00@23.00; open hearth billets, $23.00 @23.00; San Francisco, bar, 7c to 12c ₱ lb.

GENERAL SUPPLIES.

ANTIMONY. — New York, Cookson's, 7¼c; Hallett's, 6¾c; San Francisco, 1000-lb. lots, 8c; 300@500-lbs., 8½c; 100-lb. lots, 10½c.

POWDER.—F. o. b. San Francisco: No. 1, 70% nitro-glycerine, per lb., in carload lots, 15½c; less than one ton, 17½c. No. 1*, 60%, carload lots, 13½c; less than one ton, 15½c. No. 1** 50%, carload lots, 11½c; less than one ton, 13½c. No. 2, 40%, carload lots, 10c; less than one ton, 12c. No. 2, 35%, carload lots, 9½c; less than one ton, 11½c. No. 2** 30%, carload lots, 9c; less than one ton, 11c. Black blasting powder in carload lots, minimum car 728 kegs, $1.50 per keg; less car lots, $2.00 per keg.

CAPS.—3x, $5.50 per 1000; 4x, $6.50; 5x $8; Lion, $9, in lots not less than 1000.

FUSE. —Triple tape, $3.60 per 1000 feet; double tape, $3.00; single tape, $2.65; Hemp, $2.10; Cement No. 2, $3.00; Cement No. 1, $2.65, in lots of 3000 feet and up.

CANDLES.—Granite 6s, 16 oz., 40s., 11¼c ₱ set; 14 oz., 40s., 10c.

CHEMICALS. — Cyanide of potassium, 98%–99%, jobbing, 23@24c ₱ lb.; carloads, 23@23½c; in tins, 30c; soda ash, $2.00 ₱ 100 lbs.; hyposulphite of soda, 3@3½c per lb.; caustic soda, in drums, 3@3½c ₱ lb.; Cal. s. soda, bbls., $1.20@1.40 ₱ 100 lbs.; sks., $1.05; chlorate of potash, 12@13c; nitrate of potash, bbls., 10c; caustic potash, 10c in 40-lb. tins; roll sulphur, 2½@2¾c; powdered sulphur, 2@3c; flour sulphur, French, 3¼@3½c; alum, $2.00@2.25; California refined, 1¾@2c; sulphide of iron, 8c ₱ lb.; copper sulpbate, 5¼@5½c; chloride of lime, spot, $2.50@2.75; sulphuric acid, in carboys, 66% B, 1¾@2c ₱ lb.; nitric acid, carboys, 8c ₱ lb.

BONE ASH.—Extra No. 1, 5@6c ₱ lb. No. 1, 4@5c.

COAL.—San Francisco, coast, yard prices: Wellington, $8.00; Soattle, $6.50; Coos Bay, $5.50; Southfield, $8.00. Cargo lots, Eastern and foreign: Wallsend, $7.50; Brymbo, $7.50; Pennsylvania, hd., $14.00; Scotch, $8.00; Cumberland, $13.00; Cannel, $8.50; Welsh Anthracite, $13.00; Rock Springs, $11.50, long ton; Colorado Anthracite, $14.00. Coke, $10.50 per ton in bulk, $13.00 in sacks; Sunnyside, $11.50, long ton.

OILS.—Linseed, boiled, bbl., 45c; cs., 50c; raw, bbl., 43c; cs., 48c; Lucol oil boiled, bbl., 44c; cs., 49c; raw, bbl., 42c; cs., 47c. Kerosene—Pearl, per gal., 21½c; Astral, 21½c; Star, 21½c; Extra Star, 25½c; Eocene, 24½c; Elaine, 27½c; Water White, in bulk, 15c; Mineral Seal, iron bbls., 19c; wooden bbls., 21½c; cs., 25c; Mineral Sperm, cs., 26½c.; Deodorized Stove Gasoline, bulk, 17c; do., cs., 23½c; 86° Gasoline, bulk, 25c; do., cs., 31c; 83° Naphtha or Benzine, deodorized, in bulk, per gal., 13c; do., in cs., 19½c; Lard Oil, E W. S., bbl., 85c; cs., 90c; Neats-foot Oil, pure, bbl., 75c; cs., 80c; Sperm, crude, 50@55c; Natural White, 70c; Bleached, do., 75c; Whale Oil, cs., 50@55c.

WHITE LEAD.—Per lb., in kegs: 500 lbs. and over at one purchase, per lb., 6½c; less than 500 lbs., per lb., 7c; in 25-lb. tin pails, ½c ₱ lb. above keg price; in 1 and 5-lb tin cans, 100 lbs. per case, ½c. per lb. above keg price. Dry Lead—In bbls., 1 ton and over, 6½c; do. in kegs, 7c.

RED LEAD.—500 lbs. and over at one purchase, ₱ lb., 6½c; less than 500 lbs., 7c.

LITHARGE.—Pure, in 25-lb. bags, 8@9c ₱ lb.

BORAX.—Concentrated, 6@7c ₱ lb; powdered, 8@10c; fused, 20@25c; crystal, 7c; calcined, 25c.

MANGANESE.—Pure, ₱ lb., 60c.

SODIUM.—Metal, ₱ lb., $1.00.

BISMUTH.—Subnitrate, ₱ lb., $1.75.

MERCURY.—Bichloride, ₱ lb., 90c.

MOLYBDENUM.—$2.00 ₱ lb.

CHROMIUM.—90% and over, ₱ lb., $1.00.

PHOSPHORUS.—American, ₱ lb., 75c.

SILVER.—Chloride, ₱ oz., 90c@$1.00; nitrate, 55c.

ALUMINUM.—No. 1., 99%, small lots, 37c ₱ lb.; 100 lbs., 35c; 1000 lbs, 34c; ton lots and over, 33c, Pittsburg. No. 2, 90%, small lots, 34c; ton lots and over, 31c, Pittsburg.

URANIUM.—Oxide, ₱ lb., $3.50.

(These prices are wholesale, f. o. b. San Francisco, unless otherwise noted.)

New Patents.

DEWEY, STRONG & CO.'S SCIENTIFIC PRESS PATENT AGENCY, 330 Market St., S. F., has official reports of the following U. S. patents issued to Pacific Coast inventors:

FOR THE WEEK ENDING DECEMBER 22, 1903.

747,672.—BRAKE—G. E. Babcock, Coronado, Cal.

747,575.—DRILLING BIT—R. C. Baker, Coalinga, Cal.

747,847.—RAILROAD SWITCH—W. J. Bell, Los Angeles, Cal.

747,578.—CAN BODY MACHINE—H. C. Black, S. F.

747,582.—PERFORATING CYLINDERS—Boyle & Brett, Los Angeles, Cal.

747,583.—CYLINDER MACHINE—Boyle & Brett, Los Angeles, Cal.

747,536.—CLOD CRUSHER—F. E. Caton, San Jose, Cal.

747,373.—CLOSURE—E. E. Chapman, Los Angeles, Cal.

747,872.—TRACK GAUGE—Ellis & Purvis, Lester, Wash.

747,053.—BUCKLE—J. A. Gavitt, Pendletou, Or.

747,420.—BOILER ALARM—W. S. G. Harris, San Luis Obispo, Cal.

747,711.—EDUCATIONAL APPLIANCE—L. M. Hollingsworth, Fresno, Cal.

747,732.—DECOY DUCK—A. Kremer, Sacramento, Cal.

747,560.—CARGO DISCHARGER—H. A. Middaugh, Seattle, Wash.

747,567.—LEMON SQUEEZER—W. H. Ostrander, S. F.

747,656.—VALVE — F. P. Skeffington, Spokane, Wash.

747,502.—GAS GENERATOR — H. Symonds, Long Beach, Cal.

747,504.—PIPE WRENCH—L. Tarbell, Los Angeles, Cal.

747,522.—PLOTTING TOOL—L. E. Wilkes, Hillshoro, Or.

FOR WEEK ENDING DECEMBER 29, 1903.

748,342.—VAPOR BURNER—G. A. Bonelli, Kingman, Ariz.

748,472.—STOVES—L. & A. F. Brandt, Spokane, Wash.

748,046.—FLUSHING APPARATUS—J. H. Byers, S. F.

748,162.—SPLITTING MACHINE—O. E. Cheesebrough, Anaheim, Cal.

748,485.—WINDMILL—W. Curtis, Sacramento, Cal.

747,950.—BOX FRONT—F. Davis, Salem, Or.

748,267.—OIL BURNER—J. H. Davis, Oakland, Cal.

748,487.—SAFETY GAS COCK—H. J. Doll, S. F.

748,054.—UNDER-REAMER — E. Double, Los Angeles, Cal.

748,177.—OIL BURNER—E. A. Edwards, Los Angeles, Cal.

748,368.—CAN MACHINE—C. H. Hanford, Seattle, Wash.

748,071.—SAFETY PIN—B. P. Herndon, Florence, Ariz.

748,288.—KNAPSACK, HAMMOCK, ETC.—G. Klein, S. F.

748,193.—PAINT BRUSH—J. P. Kneuhmann, Sumas, Wash.

748,081.—HEAD REST—L. Larrimore, Los Angeles, Cal.

748,082.—UMBRELLA TIP—J. M. Lauhe, Whatcom, Wash.

748,209.—MAIL BAG—D. G. McClay, Santa Ana, Cal.

748,087.—MUSICAL TOP—Mighels & Ellis, Berkeley, Cal.

748,298.—INDOOR GAME—S. B. Monson, S. F.

748,204.—HARNESS SADDLE—T. I. Morrish, S. F.

748,211.—CURTAIN HOLDER—F. E. Naumann, Los Angeles, Cal.

748,094.—MEASURE—H. C. Parker, Los Angeles, Cal.

748,008.—HAT HOLDER—P. P. Rahin, Colma, Cal.

748,010.—WEIGHING MACHINE—S. G. Reed, Portland, Or.

748,309.—ELECTRIC PAD—W. Rickards, Los Angeles, Cal.

748,561.—FURNACE—E. Riveroll, Los Angeles, Cal.

748,227.—ATOMIZER—F. A. Smith, Los Angeles, Cal.

748,232.—PHOTO MOUNTS—P. J. Stuparich, S. F.

748,324.—REGISTER—C. Wamsley, Tacoma, Wash.

748,123.—ELECTRIC SWITCH — I. G. Waterman, Santa Barbara, Cal.

Notices of Recent Patents.

Among the patents recently obtained through Dewey, Strong & Co.'s SCIENTIFIC PRESS U. S. and Foreign Patent Agency, the following are worthy of special mention:

PROCESS OF MANUFACTURING PHOTOGRAPHIC MOUNTS.—No. 748,232. Dec. 29, 1903. P. J. Stuparich, San Francisco, Cal. Assigned to the Stuparich Mfg. Co. of same place, a corporation. This invention consists in a means for imprinting designs of any description upon the outer portion of the card which forms the mount and at the same time the formation of an interior smooth and unmarked portion of the size and shape designed to receive the picture which is to be mounted upon the card.

MUSICAL TOYS.—748,087. Dec. 29, 1003. P. W. Mighels of Oakland, Cal., and C. Z. Ellis of Berkeley, Cal. This invention relates to improvements in mechanical and musical toys, and particularly to that class in which musical tones are produced by a spinning top. An endless variety of tunes may be played by the same operating means, since it is possible to remove a cylinder and replace it with one for a different tune. The device is neat, simple, entertaining, and in external appearance does not differ from ordinary tops.

INDOOR GAMES.—No. 748,298. Dec. 29, 1903. S. B. Monson, San Francisco, Cal. One-third assigned to J. H. Cadogan of Oakland, Cal. This invention consists in the combination of a flexible sheet having a numbered diagram upon its surface near one end, a roller secured to the sheet and upon which the latter may be wound, said sheet projecting beyond the roller, and said roller serving as a stop for limiting the movement of playing pieces, and clamps engaging both ends of the sheet. The object of the invention is to provide a small and conveniently manipulated game to be played indoors.

SAFETY GAS COCKS.—No, 748,487. Dec. 29, 1903. H. J. Doll, San Francisco, Cal. The object of this invention is to furnish a simple device which will insure the complete shutting off of the gas when the key is turned and which will also provide means for regulating the flow of gas independent of the key.

CONVERTIBLE KNAPSACKS, HAMMOCKS AND SLEEPING-BAGS.—No. 748,288. Dec. 29, 1903. G. Klein, San Francisco, Cal. This invention relates to an improved article of manufacture which is convertible on occasion into either a knapsack, a hammock, a sleeping-bag or a section of a tent.

WINDMILL.—No. 748,485. Dec. 29, 1903. W. Curtis, Sacramento, Cal. One-half assigned to E. F. May of same place. This invention consists in a novel means of transmitting power from the wind wheel shaft to the counter-shaft by which pumping or other mechanism is driven, a means for turnably supporting the wind wheel and connected mechanism, and arrangement of a pair of pumps and their connection with the mechanism of the mill, so that they may both be disposed within the well and its casing. The invention is especially designed to avoid the use of oil or lubricants and to transmit power without the use of gearing, belts, sprocket chains or the like.

OIL BURNER.—No. 748,267. J. H. Davis, Oakland, Cal. The object of this invention is to provide a burner particularly adapted for use in stoves which is simple, cheap, clean and safe and from which there is absent the usual disagreeable and alarming noises of puffing and muffled explosions noticeable in many of the burners of this class.

SITUATIONS WANTED.

A YOUNG MINING ENGINEER DESIRES position as assistant; assayer and good draughtsman; State licensed surveyor for California. Address C. R., care Min. and Scientific Press.

A YOUNG MININC ENGINEER DESIRES POsition as Superintendent. Successful in handling men. Up to date and practical. Practiced in obtaining highest bullion output at least cost by milling, cyaniding and concentrating. Speaks Spanish and is conversaut with Mexican laws and customs. References required and given. Address "Engineer," care of Mining and Scientific Press, San Francisco, Cal.

A COMPETENT MILLMAN OF 10 YEARS' EXperience would like to take charge of a mill in any part of the country, understanding cyaniding thoroughly. Wife would like to take charge of boarding house at same place. Address W. G., care of Mining and Scientific Press.

AS ELECTRICIAN WITH MININC COMPANY; nine years of experience operating polyphase, hydro-electric power plants and direct current machinery; can make all repairs; age 26 years. First-class references; will go anywhere. F. P., this office.

ASSAYER AND CHEMIST DESIRES POSITION in mine or laboratory. Address V. H., this office.

CAPABLE BUSINESS MAN OF WIDE EXperience is open for engagement. Now holds responsible position, but desires to be permanently located with reputable mining people who can offer inducements in a solid concern. Invites confidential correspondence and investigation of character, ability, etc. Address "Effort, care Mining and Scientific Press.

EXPERIENCED SUPERINTENDENT, ENGIneer, Metallurgist; technically and liberally educated; 15 years handling men and machinery of smelters, mills and mines. See testimonials. Address Prof. Stickney, Mountain View, Cal.

EXPERIENCED MILLMAN WISHES POSItion. Address Box 202, Enterprise, Cal.

HIGH-GRADE MAN WILL ACCEPT MODERate salary. **PRACTICAL MINE FOREMAN and All Round SUPERINTENDENT.** Inquiries cheerfully answered. Address "Wire Cable," Sonora, California.

MANAGER LARGE GOLD MINING AND milling company in Arizona desires to change his location and obtain similar position with desirable company elsewhere. Best of references from present employers. Address I. C., this office.

POSITION WANTED BY NEW YORK ELECtrical engineer with Pacific Coast company. Experienced in construction work and selling. A position where he can work into the selling end preferred. References from company with which he is now connected. Address G. P., this office.

SUPERINTENDENT IS OPEN FOR POSITION to develop gold or copper properties; experienced miner; can make underground maps and models, also do the assaying; speaks Spanish; good references from past companies. Address "Develop," care this office.

WANTED, POSITION AS SUPERINTENDENT or Manager of "Gold Mining Property;" 12 years' experience in practical mining, also assayer, mine surveying and drafting. Will furnish surveying and drafting instruments, and will accept 50% of salary in stock in a "Good Mining Co." O. F. Matkin, care of Concentrator, C. C. C. Co., Cananea, Sonora, Mexico.

WANTED—POSITION BY EXPERIENCED ASsayer and Surveyor. Thorough knowledge of bookkeeping and Spanish. S. C. H., this office.

WANTED, POSITION BY MACHINIST AND Engineer; efficient in steam, electricity and compressed air; seven years' experience at mines; good references. Address Box 54, care of Mining and Scientific Press.

WANTED—POSITION AS SUPERINTENDENT or assistant of copper mines and smelters; competent all round man, good assayer, analyst and draughtsman; can handle labor; speaks Spanish. Address "Smelter," care this office.

YOUNG MAN WITH SOME EXPERIENCE and training in chemistry, metallurgy and general engineering, wants work at mine or any place where he can get additional experience and training. Address "Espanol," care of this office.

HELP WANTED.

A GOOD OPENING IS OFFERED TO A MAN OF engineering knowledge, with a large concern manufacturing power transmitting and conveying machinery, and which desires to reach the mining industry. Address Mining and Scientific Press, 1115 Monadnock Bldg., Chicago.

ASSESSMENT NOTICES.

MAYDAY GOLD MINING COMPANY.—LOCATION of principal place of business, San Francisco, California; location of works, Calaveras County, California.

Notice is hereby given, that at a meeting of the Board of Directors, held on the 9th day of November, 1903, an assessment (No. 1) of three cents per share was levied upon the capital stock of the corporation, payable immediately in United States gold coin, to the secretary, at the office of the company, at Heald's Business College, No. 24 Post street, San Francisco, California.

Any stock upon which this assessment shall remain unpaid on the 14th day of December, 1903, will be delinquent, and advertised for sale at public auction; and, unless payment is made before, will be sold on MONDAY, the 18th day of January, 1904, to pay the delinquent assessment, together with the costs of advertising and expenses of sale.

By order of the Board of Directors.

EDWARD H. STEARNS, Secretary.

Office of the Company, Heald's Business College, No. 24 Post street, San Francisco, California.

POSTPONEMENT.

The day of delinquency in the above assessment has been postponed to January 11th, 1904, and the day of sale to Wednesday, February 17th, 1904.

By order of the Board of Directors.

EDWARD H. STEARNS, Secretary.

Office of the Company, Heald's Business College, No. 24 Post street, San Francisco, California.

TANANA MINING COMPANY—LOCATION OF principal place of business, San Francisco, California.

Notice is hereby given, that at a meeting of the Board of Directors, held on the 11th day of December, 1903, an assessment (No. 7) of four (4) cents per share was levied upon the capital stock of the corporation, payable immediately in United States gold coin, to the secretary, at his office, Rooms 404-405 of the Call Building, San Francisco, California.

Any stock upon which this assessment shall remain unpaid on the 18th day of January, 1904, will be delinquent, and advertised for sale at public auction; and, unless payment is made before, will be sold on MONDAY, the 29th day of February, 1904, to pay the delinquent assessment, together with costs of advertising and expenses of sale.

By order of the Board of Directors.

EDWARD H. STEARNS, Secretary.

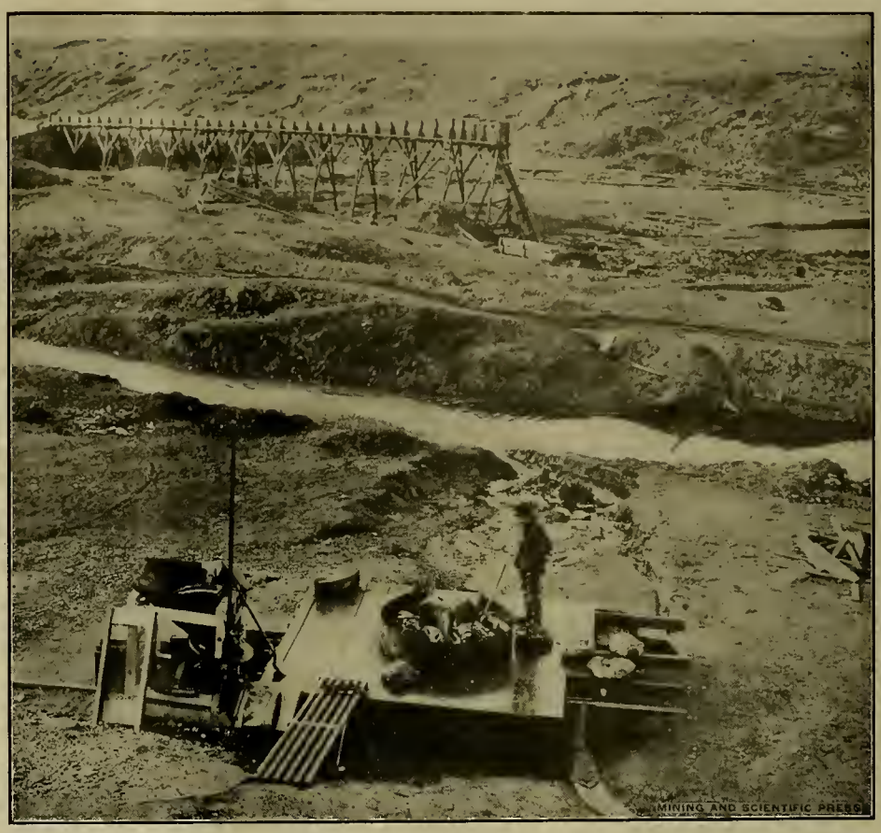
Valuing a Mine.

When a mine is sampled throughout for the purpose of ascertaining its value, the miner or engineer can determine this quantity with approximate accuracy, if proper methods be pursued. The most important thing is to take samples which actually represent the vein or ore deposit. This is a more or less difficult thing to do, but by exercising the necessary care it can be done. Samples should be taken entirely across the vein from wall to wall, and if the vein be very wide, they may be taken in sections. Each sample should be assayed separately, and assumed to represent the value of the width sampled at that point. The taking of a dozen or twenty or more samples along the level, mixing the whole together, cutting down and calling this a representative sample of that portion of the level is an unsatisfactory and dangerous method of ascertaining values, for all the values represented by the so-called sample may have come from a rich spot in the vein, a few inches in width, and as it has no considerable extent a much greater value is credited to that portion of the mine than it is actually entitled to. A third essential is the development of the mine to an extent which divides the ore into a series of blocks which expose ore on three or four sides. The day is past when large blocks of ground are admitted by engineers as an equal in value and volume to that exposed along the faces. The blocks must be comparatively small and accessible to the sampling process. Occasionally novices in mine examination permit shrewd promoters to select their samples for them, or take them themselves from piles of ore already broken in the mine. Such instances are, however, becoming fewer.



A Sand Grinder in Operation at Nome, Alaska. (See page 38.)

Placer Mining in Nome District, Alaska; Hydraulic Elevator in the Background. (See page 38.)

THERE are mining methods possible in a country where labor is cheap that are not commercially applicable in one where wages are comparatively high, unless the ore be unusually high grade. The copper mines of Cabazas del Pasto, Spain, were worked by a system of crosscutting and filling by hand, no smalls being employed. By this means very large masses of ore were extracted without danger to the workmen, but while the method of mining is applicable to many mines in America and elsewhere, the cost of handling the filling in the same manner as practiced at the Spanish mine referred to is commercially impossible. The method of working a mine is usually, if not always, a question of expediency, determined by the cost or influenced by the physical conditions present.

The Copper Situation.

Duriug 1903 copper had an interesting career, and it promises no less interesting features for the year 1904. About one year ago New York quotations for Lake copper were $11.62½ per hundred. Early in February the price had advanced to $12.75, going to $13.75 the first week in March, and before the end of that month Lake copper found a ready market at $14.50 to $15. This was the highest price reached during the year, though the price was maintained at $14.50 to $15 until June. In July a slight decline was noticeable, and, with more or less fluctnation, the price fell throughout the summer and fall, going as low as $13.12½; but ou November 1 it rallied to $14. During December the quotations fell to $12.50, and at present the quotation is $12.75 to $13. The rise in price in the carly part of 1903 was due to a large and steady demand for the metal, and the falling off in the latter part of the year is attributable to a constantly decreasing demand until the latter part of the year, when it seemed to be a game of waiting ou the part of both seller and consumer. The seller waited for large stocking-up orders, and the buyers held back in the expectancy of a lower price. The market is at present more active, and the prospect of war in the Far East has also had a material influeuce ou the price. Should war actually be declared, a strong aud materially higher market may be looked for. It is also said that, although industrial activity is less pronounced in America than a year ago, the foreign demand for copper has constantly increased. The methods of mining and treating copper ores are being simplified each year, making it possible to produce copper under giveu conditions at a lower cost than ever before. On the whole, the outlook for the copper mining industry for 1904 is encouraging, and a price at least cqual to that prevailing throughout the greater part of 1903 may be anticipated.

Relation of Placer to Quartz Veins.

In many regions producing placer gold there is noticed a marked discrepancy between the production of the placer deposits and that of the veins. In some districts this difference is more noticeable than in others. It is usually found that a relatively greater placer output than seems justified by the veins of the district is due to the character of the veins or other deposits in situ carrying gold. A series of interesting articles on the occurreuce of gold in the placers as related to vein deposits in New Zealand has been published elsewhere herein, the last chapter appearing in the current issue. From a study of the conditions in that region it would seem that the placer gold obtained is far in excess of what might have been anticipated from the occurrence of gold in veins.

In some portions of California placer gold has been mined in large amount where as far as known there are no gold bearing veins of sufficient importance tributary to the district to have afforded a tenth part of the gold found in the placer deposits. This is notably the case on the Forest Hill divide in Placer county, where a number of large and rich ancieut channels have been worked for years, making an aggregate production of many millions of dollars, while a few hundred thousand would cover all that has been mined from quartz in the same region. It is generally believed that the gold was largely derived from pockets and small rich seams of gold occurring in the foliations of the schistose and slaty country rock, and that in that region defined gold bearing veins of great coutinuity are of relatively uncommon occurrence, though there are several veins known which are being worked. In the southern Black Hills of South Dakota is an extensive placer field in which are numerous large quartz veins bearing gold. In addition to this, gold is also found in the chlorite schists accompanying the quartz veins, as at the old Queen Bee, and on Wheeler hill, near Lookout Mills on Castle creek; near Rochford, and elsewhere. While this region has produced a large amount of placer gold, there are local occurrences of gold in small gulches, where no direct connection can be traced between the placer gold and a gold bearing vein.

The occurrence of washed pebbles of iron rock, flint and other hard rocks with this gold, indicates that the gold may have been derived from some other than a local source, as the rocks constituting the bedrock of the placers contains no iron ore similar to that found in the placers and no flint nodules, both of these having undoubtedly been derived from the limestone, the uearest occurrence of which is several miles distant, although at one time, prior to the uplift of the Hills and before the great denudation had removed the sedimentary strata, the limestone, with the accompanyiug beds, extended over this entire region. Still there appears to be no doubt that the placer gold of the Castle creek region came originally from the Algonkian schists and included quartz veins, and the occurrence of foreign washed pebbles is merely coincident.

In Arizona, a few miles south of Prescott, placer gold has been found the source of which is in doubt, but in one instauce, that of English gulch, 3 miles south of Prescott, the gold was no doubt derived from iron seams in the porphyry which crosses near the head of the gulch. There are numerous instances of nuggets of gold being found in various parts of Arizona, where typical quartz veins are wanting, but in almost every case the gold has come from seams in massive rocks, usually quartz porphyry, or some other acid eruptive rock.

In some regions the formation is reticulated with small veins and veinlets of quartz carrying gold, and a rich placer field has resulted; but on following the seams and veins downward the gold gradually disappears, and the zone being too poor to pay is not developed further, though the values may reoccur in greater depth. In a district of this kind the output from vein mines is likely to fall far below that of the alluvial deposits. On the other hand, large gold-bearing deposits are known which produce little or no placer gold at all. Among the ore deposits of this class are the gold-bearing telluride ores of Lawrence county, South Dakota. In Western Australia, in Colorado and in California the districts noted as producers of rich telluride ores are also producers of rich placers in which the gold undoubtedly was derived from the telluride-bearing gold ores.

Security in Mining Investment.

The year 1903 has taught some wholesome lessons to the people of the United States. Never before in its history has there been a year similar to that of 1903. Prominent industrial stocks depreciated from 50% to 100%, and still the real prosperity of the country continued. Those concerns which were floated at greatly inflated valuation depreciated to a point somewhere near their normal value, and although the investing class lost heavily as a result of buying stocks, promising returns so large in many cases as to give rise to a suspiciou that the investment was unsound, still the great industries of the country which were founded on a conservative and busiuess-like basis, continued to prosper. With all of the euormous shrinkage in stock values, it is noticeable that there have been comparatively few failures among large firms doing business on conservative lines. It has been the middle class that has lost heavily. It was their money that helped to boom such concerns as United States Steel and the United States Shipbuilding Co.—these being two notable examples of that class of so-called securities. As a natural result of this collapse of inflated industrials, investors who are not contented with a small percentage on their money, are looking toward the mining industry as furnishing the most promising field for legitimate investment. Engineering and science have taken mining out of the realm of the speculative and placed it where it properly belongs—in the class with the best investments which the development of America affords.

Lodes Within Placers.

The Federal statute coucerning veins within placer claims is generally well understood, bnt Congressman Dixou proposes to remedy what he evidently considers a defect in the existing statute by introducing a bill providing that United States mineral surveyors when snrveying a placer location for pateut shall make an examination and report whether or not a lode or veiu exists within the boundaries of the location seeking patent. A placer is presumed to be a deposit of gravel or other debris containing gold or other valuable mineral. Ordinarily this deposit is several feet deep and often many feet in depth from surface to bedrock. What may exist beneath this mass of debris, in the form of a vein, no one can determiue until the debris be removed and the bedrock exposed. Such being the case, it is difficult to understand how the United States deputy mineral surveyor is going to arrive at a satisfactory determination of the problem—vcin or no veiu. Unless the law can be bettered by amendment, it were better to leave it as it is. If the placer claimant knows of the existence of a vein within his location, it is reasonable to presume that he will claim it as well as the placer.

THE Colorado Mine Operators' Association has perfected its orgauization, with a view of making it of permanent benefit in the development and operation of Colorado's mineral resources. It is said to be the inteution of the Association to annually appropriate $30,000, to be raised by apportionment pro rata of output among the mines represented in the organization. The objects of the assessment are stated to be to enable the Association to prosecute ore thieves; to maintain peaceful and prosperous relatious between employers and employes; to secure, as far as possible, the election of the proper men to important public offices, and bring about legislatiou beneficial to the mining industry in that State.

THE discovery of a rich mass of gold ore in a mine on Ironclad Hill in Cripple Creek district, Colorado, has stimulated mine development iu that camp. It also clearly shows that there are still many good opportunities there, eveu in the upper portions of the ore zones. It is true the future of the district depeuds, to a great extent, upon deep mining, and in this direction the mines are meeting with most encouraging results, but the rich strike referred to indicates that the upper portions of the veius should not be ueglected until thoroughly explored.

CONCENTRATES.

MICA sheets 6 to 10 inches square, "clear and perfect," are worth from $3 to $10 per pound.

✣✣✣✣

THE rock specimen from Marin county, Cal., is glaucophane schist. Glaucophane is a blue variety of hornblende, and is of common occurrence in the Coast Range of California.

✣✣✣✣

THE mineral specimens from Gilpin, Colo., one of which was marked "No. 1," are crystalline-granular quartz with epidote. There is no material difference in the several pieces, excepting that one of them contains considerable iron oxide.

✣✣✣✣

THE mineral specimen from Ashwood, Or., is stibnite (sulphide of antimony) in a quartz gangue. There is also a small amount of iron sulphide (pyrite) in the quartz. The stibnite is characteristic, showing a distinct radiated structure.

✣✣✣✣

A SMALL MINE with free water power should be worked very cheaply. How cheaply, depends upon the management and, to some extent, upon the surrounding conditions. A large vein should be mined at lower cost per ton than a small vein.

✣✣✣✣

THE mineral specimens from Liscum, Arizona, are fine-grained silica, probably an altered rock. The ores are malachite (copper carbonate), chrysocholla (copper silicate), chalcocite (copper glance). Epidote is also present in small quantity.

✣✣✣✣

THE rock specimens from Mokelumne Hill, Cal., are grano-diorite. That marked "hanging wall" is of the normal type, though much decayed. That from the foot wall is evidently a separate intrusion or dike. It is much more siliceous than the hanging wall rock.

✣✣✣✣

NOVACULITE is a fine-grained siliceous rock used for whetstones. It is supposed to be calcareous ooze, in which the calcite of the original mineral has been replaced by silica. The novaculite of Arkansas is an aggregate of micro-crystalline grains of quartz sand.

✣✣✣✣

ONE of the largest "inverted syphons" for carrying water across a canyon for mining use was that built in Butte county, Cal., in 1870. It consisted of a wrought iron pipe 30 inches in diameter, 14,000 feet long, and at the lowest point of the line sustained a pressure of 1000 feet.

✣✣✣✣

A FAULT in a vein sometimes produces a local enrichment of the vein above the plane of the fault. Some cases of this character have been observed where the displacement was scarcely noticeable, being merely a floor which reached across the vein and extended into the walls.

✣✣✣✣

STEAM being discharged from a boiler at 85 pounds pressure into a tank having 7.5 pounds pressure, 57 pounds of steam would pass per minute through an orifice of 1 square inch. A boiler with grate area 60 square feet; heating surface 1800 square feet; steam pressure 85 pounds per square inch, would require a steam pipe 6¾ inches diameter.

✣✣✣✣

THE duty of the miners' inch in placer mining depends upon the volume of water used, character of material washed, grade and width of sluices, and in hydraulicking also upon the pressure employed. An average duty is stated to be about 3.6 cubic yards per inch, though at different mines ranging from about 2 yards to over 4.

✣✣✣✣

DETAILED COSTS of aerial wire ropeways have been frequently given. The one at the Camp Bird mine, Ouray, Colo., is 2 miles long. It carries about 300 tons per day at a total cost, including maintenance, of 20 cents per ton. It has a daily capacity of 450 tons, and if run to its limit the cost would be about 12 cents per ton of material carried.

✣✣✣✣

POWDERED CRYOLITE is used at the United States Mint to make thick, pasty slags more liquid. Its chief use is in melting the screenings and pot-scrapings where boneash is likely to be present, probably forming a fluoride with the phospborus in the boneash. It is claimed that cryolite is also useful in making siliceous slags more liquid, forming fluosilicates.

✣✣✣✣

ALMOST every mine contains more or less ore too low grade to pay the expenses of mining and milling, but which would pay to mill were it on the surface. In such cases, if it becomes necessary to break down the ore and to hoist it to the surface, it should be milled: for, while not profitable as a whole, it pays more than the expense of milling and reduces the cost of mining it.

✣✣✣✣

IN sampling the floor of a level, the only way in which even approximate accuracy may be attained is by cleaning away all loose debris from the ore to be sampled, and cutting good-sized trenches entirely across the ore body or vein. These channels should be not less than 2 feet wide and a foot deep. In a trench of this size each 7 feet of the crosscutting trench will produce about a ton of ore, in ordinary quartz rock, all of which should be taken. The difficulties of sampling the floor of a level or drift are numerous, and are multiplied where it is wet; but by taking large samples, as above suggested, a fair idea of the values present may be obtained. If the rock has to be blasted and flies badly, even larger cuttings should be made.

✣✣✣✣

THE output of gold of the Saskatchewan region has been small in the past. Possibly the gold commissioner of Canada could furnish data on the subject. The fact that dredgers are operating near Edmonton is indicative of the presence of gold. That country should be a good one in which to prospect for gold gravels on the benches and for quartz near the stream sources.

✣✣✣✣

WHERE an agent or an administrator fails to do assessment work on an unpatented mining claim, the location becomes subject to relocation, the same as when the principal neglects to conform to the requirements of the mining law. A claim located in 1902, upon which no assessment work was done in 1903, is now subject to relocation, unless the owners have begun work on the claim.

✣✣✣✣

ALL duties on all grades of coal were rebated during 1903. On Jan. 15, 1904, the duty of 67 cents per ton on bituminous coal was restored. In the first nine months of 1901 1,456,074 tons coal were imported into the United States, paying a 67 cents per ton duty: in the corresponding months of 1902 there were imported 1,533,042 tons; in the first nine months of 1903, with all duties rebated, 2,867,061 tons were imported.

✣✣✣✣

GOLD dredging in California is mostly confined to the Sacramento valley field, situated at an elevation only a few feet above sea level, but in San Bernardino county, at Holcomb valley, a steam shovel was employed some years ago to work a dry placer deposit at an altitude of 7500 feet. The quantity of water obtainable for washing the gravel curtailed the extent of operations there. Dredgers are also operated at Breckenridge, Colo., at an altitude of 9500 feet.

✣✣✣✣

REPLYING to a query from Socorro, N. M.: The deposit on the zinc, thought to be gold, is probably not gold, but bright metallic copper, having the color and luster of gold. The company referred to still receive royalty for the use of the zinc precipitation box patented by them. The several hooks on cyanide process are all compilations and contain essentially nearly the same material. Those of Bosqui, Parks, James and Eisler are about equally good. The latest hook is that of Carleton on the practice in Western Australia.

✣✣✣✣

REPLYING to a query in re—a mill site on a placer claim: It might depend somewhat on the nature of the deed executed by A to B. At all events, under the circumstances stated, the court will doubtless find some satisfactory method of preventing A from acquiring B's mill built upon land purchased from A, even if it be driven to the necessity of finding as a matter of fact that the land was sufficiently non-mineral to justify the location as a mill site. Moral equities frequently outweigh technical points in adjudicating lawsuits.

✣✣✣✣

THERE is often a slight difference between the nominal and actual inside diameter in inches in the dimensions of standard wrought iron and steel pipe. Where the nominal inside diameter would be ¼ inch the actual inside diameter would be .27 inch. The actual outside diameter of that size would be .68 inch, and the weight per foot .24 pound. In the case of pipe with nominal inside diameter of 1 inch the actual inside diameter would be 1.048 inch, the actual outside diameter 1.315 inch; thickness, .134 inch; weight per foot, 1.67 pounds.

✣✣✣✣

THE amount of evaporation in the open air is difficult of determination, depending on many and frequently changing factors. Among these the most important are humidity of the atmosphere, velocity of the wind and heat of the sun. Evaporation proceeds much more rapidly in the dry desert regions than in humid regions. The amount of evaporation varies greatly in the same district at different seasons of the year, and also in different years. The average amount of daily evaporation for the entire United States has been stated to be 0.4 inch per twenty-four hours, or 146 inches annually, but the range is far greater than this as between a humid region and a dry one.

✣✣✣✣

IN the concentration of ores it is inadvisable to return a middlings product to the same machine over which it has once passed, for the reason that if a complete separation was not effected on the first passage it is not likely to be effected on a second or a third. This process will result in the accumulation of a middle product which goes neither into the tailings nor to concentrates, but continues in circulation with a constant addition of like material from the headings, until the machine is overloaded, and inferior work is the result. The fact that a middle product occurs at all is sufficient proof of the necessity of sizing and classification before attempting concentration on any machine.

✣✣✣✣

A JIG consists practically of a screen or sieve set in a box and immersed in water. The sieve is given a rapid up and down short motion and the particles of mineral of high specific gravity settle through the lighter material to the screen. There are many types of jigs. The plunger jig differs from that above described. In the latter the screen is stationary, and a plunger or piston is placed in a compartment adjoining that in which the screen is fixed. The rapid rise and fall of the plunger imparts a pulsating movement of the water which causes a separation of the heavy and light particles in the screen box, in a manner similar to that previously described. Jigs generally treat a coarser ore than is treated on other classes of concentrating machines.

✣✣✣✣

A SECURE and water-tight dam can be made in a mine, in a drift or crosscut, by selecting a place where there is a rock projection, or a channel can be cut in the rocks, to give the dam a secure foundation. Planks should then be set on edge to the height of the dam. A second line of plank should then be placed from 15 to 20 inches from the first, held in position by a post set on either side of the drift and on the farther side of the dam. If the dam is only temporary, the space between the walls should be filled with clay. If for permanent use, concrete may be substituted for clay. During construction a pipe may be laid in the dam extending through to the inside, and provided on the outside with a valve to control the flow of water. A disused crosscut or drift may be utilized in this way as a tank or reservoir to catch up and hold the mine water that may be conducted to it. The water may be pumped from this tank or sent out in skips at any time when it becomes convenient, and the expense of cutting a tank below a level is obviated.

✣✣✣✣

IN the determination of minerals, the hardness is always one of the first things consulted. The relative hardness of minerals is as follows, and is used for comparison: Talc 1, gypsum or halite (crystals of salt) 2, calcite 3, fluorite 4, apatite (crystallized) 5, feldspar (adularia) 6, quartz 7, topaz 8, corundum 9, diamond 10. Color, streak (color of powdered mineral); crystalline form, gravity and fusibility are other physical characteristics. There are three grades of fusibility: Those minerals which fuse to a bead, those which fuse only on the edges and those which are infusible. Several minerals are recognized as characteristic of fusibility: 1. Stibnite (antimony sulphide), fusible in flame of a candle in coarse splinters. 2. Natrolite (a silicate of alumina), fusible in candle flame in fine splinters, before the blowpipe easily fused in coarse fragments. 3. Almandite (iron alumina garnet), infusible in candle flame, easily fusible before blowpipe. 4. Actinolite, less easily fusible than almandite, but fusible in coarse splinters. 5. Orthoclase, fusible in fine splinters. 6. Very difficultly fusible; only rounded on the edges in very fine splinters.

✣✣✣✣

SOME ROCKS appear to swell upon becoming decayed by meteoric agencies. In some grano-diorite this is particularly noticeable, where the rock encloses quartz veins. The veins are found fractured from wall to wall at regular intervals, the distance depending apparently on the width of the vein. The floors occur at a greater distance apart in large than in small veins. These floors separate the vein into blocks which have been drawn apart, apparently, by the swelling of the enclosing rock, which has lifted the blocks by a stretching process. Still, the country rock does not appear to encroach upon the spaces between the blocks, for the spaces are usually more or less completely filled with clay-like mineral and quartz sand, and where the vein is gold bearing, this clay and sand is found to be gold bearing also, and generally to a greater extent than the vein quartz itself. When in depth, the granite or grano-diorite is found unaltered, these floors may still be found, but the vein is not divided into separate blocks, as nearer the surface. Many quartz veins are found fractured transversely from wall to wall at right angles to the dip, and this has in some instances led to the mistaken belief in some large veins, prior to their development, that the vein dipped in a direction opposite to that which it really had. This is a structural feature of no economic importance.

✣✣✣✣

SOME stamp mills have a series of mercury traps in the line of plates. These traps are arranged to extend entirely across the plates, and consist of a slot 3 inches wide. In the center of this slot is placed an inch board which also extends entirely across the width of the plate. The lower section of the plate at each trap is placed at least 2 inches lower than the section immediately above it. The pulp passing over the plate next the mortar falls into the first slot or trap, and flows beneath the center board rising on the opposite side and flows over the second section of plate, at the lower end of which is arranged a second similar trap. In addition to this the plates are sometimes arranged in a series of low steps with a fall of ½ to ¾ inch. This, some mill men believe, facilitates amalgamation. A low drop with some ores is undoubtedly beneficial, but if too high a drop be given the plate will be scoured by the falling sand and water. It is good to run the head of the plate table as nearly normal as possible or a trifle "dry," the central section "wet" and the lower end dry. The theory upon which this practice is based is that a normal plate (one in the best possible condition) is supposed to catch a large percentage of the free gold present. The middle section is run wet to catch any particles of gold or amalgam that may be scoured or in any other way escape from the upper section, while the dry lower portion will catch any globules of quicksilver that may be carried down from the soft middle section. The traps above described are put in as a precautionary measure.

Mining Progress in Alaska.

Written for the MINING AND SCIENTIFIC PRESS.

The goldfields of Alaska are as yet comparativcly little kuown. The Seward peninsula, which embraces the extreme northwestern portiou of Alaska, herctofore known as Nome, is bnt little developed outside of the immediate vicinity of the Nome and Council districts, which are about 75 miles apart. The introductiou of capital and enterprise duriug the last two years has resnlted in the building of railroads, construction of water ditches and the introduction of the latest and most improved hydraulic mining machinery. Every available water snpply within the above-named districts has been appropriated and the work of constructing ditches has made rapid strides. Among the first to nndertake the making of extensive ditches was the Miocene Ditch Co. of San Francisco, Cal. This company began the constructiou of their ditch in 1901, but the system was not completed until midsummer of 1903. This water system takes its main supply from Nome river and the tributaries along the lines of the ditch. The main ditch is 30 milcs long, with branches which aggregate over 40 miles of ditch, the capacity beiug 3000 inches. This supply of water covers a district embracing Dexter, Anvil, Glacier and Dry creeks and their tributaries. A great part of the gravel deposits covered by the Miocene Ditch Co., in fact, most of the entire district, lies low and flat, requiring hydraulic elevators to successfully work them. In order to demonstrate the efficiency of the hydraulic elcvator, the Miocene Ditch Co. installed four of these plants during last season on Glacier and Anvil creeks and operated them successfully.

Hydraulic Elevator Lifting Gravel 45 Feet From Pit; Raising Upper Sluice to Secure More Dump, Nome, Alaska.

On Ophir creek, in Council district, the Wild Goose Co. began the construction of a large ditch system iu the season of 1903, aud they also installed three elevator plants. The operators of these two companies have demonstrated what operations can be done with hydranlic elevators wherc water is available. Numerous other companies have begun the construction of ditches and will next season put in similar plants. Where water for operating elevators is not available, dredgers are being built and will be used along the rivers and other low-lying deposits. So it is expected that a large increase in the yield of gold from the Nome aud Council districts will result in the near future.

In the Kugarok, Iumuchuk, Kobuk and other outlying districts little has been doue except what the single-handed prospector has done, which has proven that extensive areas of gold-beariug country only await the coming of capital and railroads to open them up and make them large gold producers. On the Arctic side of the Seward peninsula lies an extensive system of crecks known to contain gold, but as yet very little is known of their richness.

The elevators operated by the Miocene Ditch Co. on Anvil and Glacier creeks during the season of 1903 worked under different conditions, iu some cases elevatiug the material a vertical height of 48 feet and discharging over 1000 cubic yards of gravel in twenty-four hours. This was accomplished with 400 inches of water. The situation and method of working these elevators are shown iu the engravings.

The fact that gold-bearing gravels can be thus successfully operated in a region uutil recently supposed to be perpctually icc-bound is interestiug to miuers, particularly to those eugaged in similar mining elsewhere.

Gaseous Fuels for Power and Heating.

Written for the MINING AND SCIENTIFIC PRESS by H. SHERWOOD, C. E.

This paper is iutended as a digest of recent knowledge of the use and production of gaseous fuels, viz: The natural carbonaceons fuels converted by generators into gaseous form, and employed to obtain motive power through their explosion and expansion in gas engines, or as fuel in industries where high heat is required to act upon metals, minerals, etc.

All admit the importance to industrial works of an economical source of motive power. Whatever cheapens it, goes far toward allowing many operatious to be profitably conducted, and even allowing dividends to be paid on capital. Motive power is so largely needed in such works as orc mills, electric smelting, electrolytic refining, metal working, etc., as to be a primary cousideration in establishing the works. For example, stamp mills for gold ores: In most of these wcst of the Rocky mountains, the average mill, with its accompanyiug ueeds for power, requires not far from 1 H. P. for each ton of ore treated in the 24 hours. Taking 100 tous, the cost of power by steam pcr horse per 24 hours in inland districts caunot be assured to average less thau 16 cents per horse power per 24 hours. Suppose the possibility of reducing this by 50%—the economy reaches an annual sum equal to a dividend of over 7% on $40,000 capital. Take electrolytic refiniug as a further example—needing 30 H. P. per ton by cupric salts. In an output of ten tons a day, taking motivc power at 14 cents a horse powcr for 24 hours, the economy of 50% would enable an anuual dividend of 6½% on $120,000. No other illustration of the importance of the subject is needed, nor of the help to large industrics if the supposed economy can in practice be assnred, even in cases where large motive powers are used, to justify a change from existing practice to the more economical system, seeing that the change would be more thau recouped during the first twelve months.

We know that the power possible from heat by combustion of fuel in forming steam is not yet able to be sufficiently utilized; heat cannot rapidly enough pass through boiler plates to water within. Steam is, therefore, a partially effective agent of power. The hot air engine on Ericson's type involves insnfferable cost of engines in proportion to their power. The gas engine is a hot air engine and for large powers seems to be at present the only satisfactory meaus of employing heated gases. Considcring that the explosion of combustible gases iu an enginc cylinder may reach a heat of 1700° C., which gives an expansive power to air, and most gases, of about seveu atmospheres—close upon $\frac{1}{100}$ pressure per square inch—(expansive power being about $\frac{1}{2\frac{1}{3}}$ of volume for each degree Centigrade of heat attained) heated air justifies the assigning to it of a uew phase of usefulness which cannot be wisely neglected, seeing that water gas is so convenient a source of heat. And, thc improvemcnts which are coutinually growiug upou an already satisfactory agent in the form of easily obtaining gases of higher heating power up to 2700° C., and of engines adaptcd to make the most of the resnlting power, add to the value of these gaseous fuels, and their iucreasing importance now and iu future years.

Comparison of economy of motive power is limited to steam, gaseous fnel and electric cnrrent got by use of large water powers. To compare requires to see how mnch of gaseous fuel is cousumed to produce power, and at what prices they can be produced from various natural fuels.

Water gas is the result of a train of reactions effected by heat whereby the carbon of the natural fuel is made gaseous, combustible carbon mouoxide, throngh the carbon combining with the oxygen of watcr setting free its hydrogen. This pure water gas contains as much as half its volume of hydrogen, which gives out on combustion with oxygen the highest heat of any gaseous combustion. Water gas is therefore an artificial store of caloric, which, being thus concentratcd, cau be given out at any point or moment where intense heat is needed. This property is heightened by the fact of the carbou being monoxidc, as the water gas needs for explosion with air much less cold air thau does gas distilled from coal—the former needing 2½ to 3 parts of air for explosion in place of 5 to 8 parts of air for the latter. This allows the full effect of the heat of explosiou without waste.

The first gaseous fucl thus employed was uot water gas, but what was known as "producer" gas, which

Elevator at Specimen Beach, Anvil Creek, Nome District, Alaska.

is a carbon monoxide with the nitrogen contained in the air which burned the carbon to monoxide. This gaseous fuel is becoming largely employed as a source of power in iron smelting works, being a product of smelting. Gas engines of large cylinder are being run by these gases, formerly wasted into the air—as much as 700 H. P. being run by one iron working establishment. The report from them is that 200 H. P. engines are being run along steadily year after year with little or no stoppage, insuring a very large economy.

For smaller powers a richer gas than this is needed to insure complete quick explosion. There was, therefore, brought into use the same gas mixed with pure water gas, both gases being produced simultaneously in the same generator. This is the Dawson "poor" water gas of England and the Lencanchez gas of France. The former is employed in most of the Otto gas engines and the latter in most of the Simplex engines. Both are very effective and regular in action and extremely economical. In addition to the constituents of pure water gas, these working gases are half their volume inert nitrogen. They therefore require but 1½ to 1¾ volumes of air for their explosion in place of double that amount for pure water gas, or quadruple or sextuple that amount for rich gases. The inert gas in this poor water gas being half the volume, the smaller amount of nitrogen required to be added with the oxygen of the air, makes the total inert gas in the volume compressed in the gas engine to be about 5 as compared with 4 in pure water gas. This "poor" gas requires about one-fourth more consumed to give out the same power. The increase in volume allows of stronger compression in the cylinder before explosion, which is advantageous in expansion when heated. The volume of this gas from the same fuel being double that made into pure water gas, economy is decidedly found in the gas. It has become the standard gas in use for power—running probably 90% of all the engines in use, except the small engines in cities, which, for convenience, use gas from the city gas mains. Recent improvements in making water gas aim at substituting hydrogen for inert nitrogen in the gas, thus obtaining higher heating power from the same original fuel. These efforts have found much success, which will be noticed in discussing the various fuels, but no improvements have lessened the carbonic oxide by bringing hydrogen into union with carbon in place of oxygen with carbon, a most desirable and almost impossible problem.

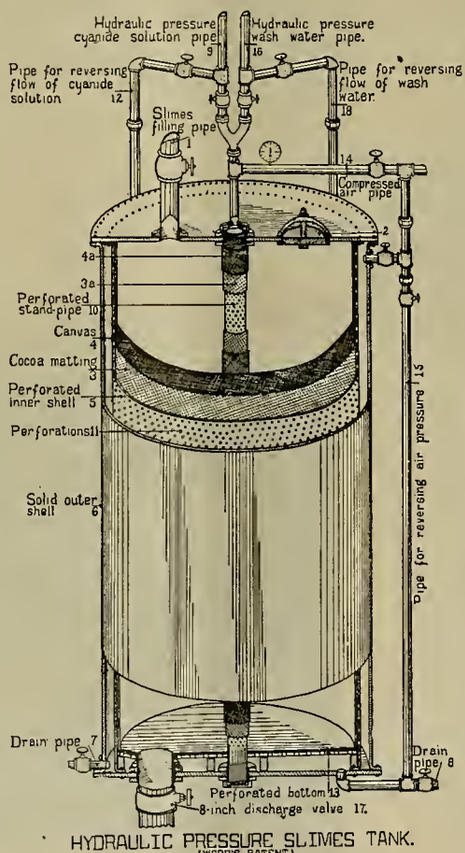
A primary consideration of cost of power needs its present cost by steam boiler and engine to be shown. In very large powers—say 800 H. P. and upwards—the splendid Corliss compound engines, fed by the most economical steam boilers, leave little to be hoped for in further economy of steam. Some of these are producing power by an expenditure of 1.2 pound of best steam coal per indicated horse power per hour—a generation ago considered impossible. It is not with these we have to deal for comparison with gas engines for popular needs. The quality of fuel used for these engines is debarred by costs and freight for use inland on the Pacific slope. Most engines there produce power by an expenditure of 2 to 2.5 pounds of fair coal per horse power per hour. In inland mills even this is debarred by freighting distance. Air-dried pine wood is employed in its place. Of this, 2½ tons equal in steam producing 1 ton of fair coal. The ordinary cost of such wood at the mills is about $4.50 per cord, weighing 1¾ ton. This makes a cost of 16 cents per horse power per 24 hours for fuel. Petroleum has been used for some time past in place of wood. By the consensus of users' experience 3½ barrels, or about ½ ton, produces steam equal to 1 ton of fair coal—being a value of $5.85 for petroleum against $7 for coal. These prices are high through rates of freighting. The cost of petroleum for steam is also about 16 cents per horse power per hour. It must here be borne in mind that the use of petroleum is conducted with steam sufficient to literally convert it into water gas at the time of its combustion. Thus nothing is lost in smoke nor in distilling hydrocarbons. We may, therefore, take 16 cents per horse power per 24 hours as the cost of fuel in producing steam in inland California, with a similar average elsewhere on the Pacific slope, and with this we may compare the cost of power by gas. A second calculation is of importance, viz: the relation between the use of gaseous fuel employed under a steam boiler to produce power by steam and the same gaseous fuel used to produce power in a gas engine. This comparison has rarely been made. It was made conclusively by the Westinghouse Engineering Co., of Pittsburg, Pa. In this test it was found that there was required 52 cubic feet of the rich gas employed to produce each horse power by steam generated by it under a good multitubular boiler during 1 hour. The same amount of power was obtained from 18 cubic feet of the same gas exploded within the cylinder of a gas engine—a ratio of 1 to 3. Recently a similar test was made in North London, with the result that the power obtained by the gas engine was equal to that obtained by 2½ times the amount of the same gas employed in generating steam.

At first water gas was produced from coke or anthracite. In Europe these fuels have generally to be freighted long distances, and therefore many improvements have adapted the generators to local fuels—lignites, low-class bituminous coal, wood, peat, astitki (i. e., refuse from distilling petroleum), shales, etc. All these contain hydrocarbon gases, with tarry matter, oils, resins, etc., which all need converting into fixed gases, and recent improvements accomplish this effectively. Other improvements effect the production of a much larger quantity of pure water gas than before from the same expenditure of fuel and time, whilst others are fitted to act on petroleum and petroleum waste and on heavy shale oils. Every engineer will notice at first glance that in every case the constituents of the fuels are different from those formerly employed; and, therefore, bringing into play further reactions. In some of these fuels hydrocarbons form a large percentage. This is in favor of forming a water gas rich in caloric. Either the hydrocarbon becomes fixed gas, as such, or else the H is set free by the C uniting with the O of the water to form CO, setting the H of the water free. In either case the water gas becomes richer by the addition of H and C, and this without adding U. This last reaction is plainly what takes place with petroleum and its waste and heavy shale oils. When petroleum was first shown in San Francisco, Cal., as burning with steam (in about 1875 in Messrs. Garratt's brass foundry by Dr. Ireland, then of Watsonville, and in London by Professor Rankin, before the United Service Institution), it was declared impossible to use so intense a heat under a steam boiler. Now, no fuel furnishes steam so well, and it constitutes a water gas containing over 60% hydrogen—of immense value to the metal smelter as a reducing gas. The volatile hydrocarbons of the fuels quoted above, when used in the improved water gas generators, are conducted through the incandescent carbon to be converted into fixed gases along with the vapor of water—the carbonized or charred fuel continuously reinforcing the incandescent carbon as it wastes, but in some cases, notably in employing wood as fuel, there is found in water gas considerable hydrocarbons in the form of marsh gas and methane. It may be due to a lowered temperature of the carbon. In every case the water gas is richer in hydrogen, which is the object desired.

(TO BE CONTINUED.)

Hydraulic Cyanide Tank.

Herewith is illustrated a hydraulic cyanide tank, designed by the Hydraulic Cyanide Tank Co., 306 Boston building, Denver, Colo., as a method of extracting the values held in the slimes by forcing the cyanide solution and wash water through them by



HYDRAULIC PRESSURE SLIMES TANK.
(WEBB'S PATENT)

hydraulic pressure and without packing them into an impervious mass.

Mr. Jean F. Webb, the president of the company, says that this tank can be used in dry crushing mills where the dust or slimes are collected by sizing screens or baghouses; in wet crushing mills where the ore is amalgamated and concentrated and the tailings and slimes treated by cyanide; and that it is valuable in cyanide mills where is adopted the practice of wet crushing with stamps, using the cyanide solution as battery water and separating the sands from the slimes before treatment.

The accompanying engraving is a front view of the tank, showing the construction of both the outer and inner shells (parts of which are broken away), and the perforated central pressure standpipe, connected with which are the hydraulic pressure pipes for the cyanide solution and the wash water, as well as the pipe for the compressed air; the arrangement of pipes and valves for reversing the flow of solution, wash water and compressed air from the central pressure standpipe into the annular space; the arrangement of the filters on sides, bottom and central pressure standpipe; the bottom discharge valve, etc., every part being numbered in accordance with the following description of its use in wet crushing cyanide mills where the solution is used as battery water, viz.: The slimes are run into the drainage and leaching tank through the filling pipe No. 1; the liquid contained in them drains out through the filtering materials No. 3 and No. 4 and the perforated inner shell No. 5, and is caught and held in the annular space between the inner shell No. 5 and the solid outside shell No. 6, from whence it runs out through the drainage pipes No. 7 and No. 8, and is conducted through the precipitation boxes.

Filters No. 3 and No. 4 are designed to prevent the slimes from running through with the solution, it being intended that they gradually settle on the bottom of the tank and accumulate until there is a sufficient amount for treatment, the supply then to be cut off by closing the valve in the filling pipe No. 1. The manhole No. 2 is then closed, the valve in the solution pipe No. 9 is opened, and fresh cyanide solution is admitted into the central pressure standpipe No. 10, which is surrounded by the filtering materials No. 3a and No. 4a. The hydraulic pressure of the column of cyanide solution is designed to force it continuously through the pulp and out through the filtering materials No. 3 and No. 4 and the perforations No. 11 of the inner shell No. 5, to drain into the annular space between the outer solid shell No. 6 and the perforated inner shell No. 5, thence to be carried off through drainage pipes No. 7 and No. 8, passing through the precipitation boxes into a sump, there to be standardized and pumped to the top of the solution column again, this operation to be continued until the values are all dissolved, when the supply of solution is to be cut off.

"If," say the manufacturers, "during the leaching process the pressure radiating outwardly from the central standpipe No. 10 should pack the pulp on the side filters and interfere with the drainage, the flow of the solution can be reversed by conducting it through the branch pipe No. 12 into the annular space between the two walls, thus forcing it inwardly through perforations No. 11 and filters No. 3 and No. 4, freeing and cleansing them, and draining off through the perforated bottom No. 13 and the drainage pipe No. 8. This cleansing may be supplemented by introducing compressed air into the annular space through the air-reversing pipe No. 15, which will thoroughly open the pores of the filters. Should the filters on the perforated bottom No. 13 become clogged, the solution can be introduced between the solid and perforated bottoms through the lower portion of the pipe No. 12, so that it will rise upwardly through the perforations and filters, freeing and cleansing them, and drain off through the side filters and out through the drainage pipe No. 7; and this may also be supplemented by introducing compressed air under the perforated bottom No. 13 through the lower portion of the air-reversing pipe No. 15."

When the leaching is completed, compressed air is admitted into the pressure standpipe No. 10 through the air pipe No. 14, the intent being to compress the pulp and squeeze out the gold solution held therein, this pressure of the compressed air to be alternately reversed through the pipe No. 15 until the pulp is as dry as desired. Wash water is then admitted into the pressure standpipe No. 10 by opening the valve in the hydraulic water column No. 16, and, forced by its own pressure through the leached mass to wash out the remaining values, is caught in the annular space and discharged through the drainage pipes No. 7 and No. 8.

After being thus washed, the leached and worthless pulp is designed to be discharged from the tank by opening the bottom discharge valve No. 17 and turning on the pressure of the water column No. 16, alternating the flow of water through the pressure standpipe No. 10 and the reversing water pipe No. 18 until the tank is empty and the filters clean.

TURQUOISE has been discovered in a new and hitherto unsuspected region, says the American Jeweler, in the middle-eastern part of Alabama, at several points near Idaho, Clay county, about 95 miles due east of Birmingham, in the region of the Talledega mountains. Some copper mines were previously located in this vicinity. The turquoise seems to be of two distinct varieties—one yellowish-green, occurring in veins from ⅛ to ¾ inch in thickness, and resembling the New Mexican material, which frequently improves in color at a greater depth; the other is a bluish variety penetrating a gray matrix in all directions in seams spreading out from ⅛ inch thick to the thinness of paper. The color, however, is more blue and the occurrence more distinctly resembles that of

the Persian mineral. One of the localities has been mined somewhat. The mine was discovered accidentally by the finding of a piece of turquoise on the surface. Then an opening was made and a considerable quantity was obtained, but no regular mining has yet been done.

Development and Operation of a Mine.

NUMBER IV.—CONCLUDED.

Written for the MINING AND SCIENTIFIC PRESS by W. H. STORMS.

There are many mines in operation where the management employs a clerical staff in the office to keep the records of the mine's operation, and each month this staff, comprising one or more men, makes out the pay roll, records all supplies received and charges the various departments with the materials consumed, crediting "stock," etc. A cost sheet is made up from these books, together with tags handed in by the heads of the various departments. This cost sheet is more or less elaborate, according as the manager desires to keep advised of the detail of work under his direction. In some instances the deductions and refined division of costs are little better than a guess, made on averages, and are not as accurate as the number of decimal places carried out would seem to indicate.

A system of cost keeping is valuable, and should be adopted at every mine, large or small; but to render such sheets as accurate as possible, the several departments of the mine must keep separate sheets, which in themselves form a daily record of work, the results accomplished and the expense entailed. No department of mining work is more interesting nor more worthy of careful attention than that of shaft sinking. The accompanying tabulated chart of work performed at a mine will illustrate the idea. It is assumed that a three-compartment vertical shaft is being sunk, two machine drills being in use. The record is for a single month, of which the operations of the first three days and the last day of the month are recorded. The situation is ideal and the figures given represent what may be assumed to be an average condition. There is comparatively little water to handle, and fair progress is made by a small crew in a shaft of moderate dimensions in fairly hard rock. The sheet does not deal with costs; these items, comprising cost of supplies and materials used, and cost of labor, including its apportioned expense of hoisting, etc., are worked out in the office from tags supplied daily or weekly by the foremen or superintendent. The working sheet affords an excellent check for the use of the superintendent, who can not always be present, he trusting in his foremen to faithfully report the progress of work in its detail from shift to shift. A daily or semi-daily visit of the superintendent should be sufficient to keep him thoroughly posted as to conditions and the progress of work. It serves as a check against any irregularity, and any unusual occurrence is noted on the sheet. It also serves a useful purpose in keeping a record of missed holes and their cause as nearly as can be ascertained. A sort of friendly competition also results between the several shifts, and the outcome is a better average of work. This may be further increased by a system of premiums for work accomplished over a maximun result required. After a record has been established, it acts as a constant check upon the men themselves, for they can not lag without the tell-tale sheet making the fact known to the superintendent, who is likely to investigate the cause of the falling off in results. A study of the sheet may show where, under other conditions, further columns may be added to advantage, as, for instance, if sinking on a vein, the size of the vein can be recorded each day, or every 5 feet. The tonnage of ore hoisted is also recorded, and its net value is credited to the cost of shaft sinking.

RECORD OF SHAFT SINKING AT NO. 1 SHAFT OF SKY LINE MINE, JANUARY, 1903.

Day.	Shift.	Time drilling.	Holes drilled.	Feet drilled.	Holes fired.	Time of blasting.	Holes missed and cause.	Time mucking.	Skips rock hoisted.	Skips water hoisted.	Time timbering.	Sticks powder used.	Caps used.	Feet fuse used.	Candles used.	Depth of shaft.	Total feet for month.	Remarks.
1st	1	7:30 A. to 12 M.	8	45	8	12:15 P.	1—Cut off.	12:45 to 3 P.	12	0		40	8	58	6	702		Fired cut holes, 2 machines used; shaft down 702 feet.
	2	5 to 10:30 P.	10	52	10	11 P.	0	3 to 4:30 P.	5	3		50	10	63	6	....		
	3	4:30 to 6:30 A.	6	13	6	6:50 A.	0	11:30 P. to 4 A.	24	4		18	6	36	7	706		Squaring up at end of shift.
2nd	1							7:15 to 8:30 A.	7	4	8:30 A. to 3 P.				7			Finished timbering 3 P. M.; water falling off.

The Montezuma Lead Mine.

Shortly after Henry Wickenburg discovered the Vulture mine in Maricopa county, Ariz., many prospectors were attracted to the locality, and among them was one J. Swelling, who discovered an ancient shaft in which there were numerous stone hammers which had evidently been used by the same race of ancient people that inhabited the Salt River valley before the Pima and Maricopa Indians. On account of the danger from the Apache Indians, who then infested that part of the country, no work was done on this property until some ten or twelve years later, when Swelling returned. With the assistance of his partner the ancient shaft was cleaned out and about 10,000 tons of ore was taken out and shipped to reduction works in San Francisco, Cal. At that time it was necessary to haul the ore across the desert to Ehrenburg, on the Colorado river, then on barges it was sent down the river to the Gulf of California, where it was placed on steamers bound for San Francisco. Notwithstanding the high transportation charges the grade of the ore was sufficient to give a handsome return to Swelling and his partner.

In 1880 the mine was purchased by Eastern parties, who shipped some 40,000 tons of ore, hauling it to Maricopa and then shipping by rail from there to Benson, where a silver-lead smelter was in operation. Then the mine was purchased by Frank Ryland, who worked the property until his death in the early nineties. Arizona and St. Louis parties acquired the property when the estate was settled, and they are now preparing to install a concentrating plant and operate it on an extensive scale.

The Montezuma mine is located ¼ mile from the Hassayampa river, and about 3 miles west of Hot Springs Junction on the main line of the Santa Fe, Prescott and Phœnix railroad. The group to which the Montezuma belongs is known as the Black Jack, and the group consists of four claims and two millsites. Through two of the claims runs a fissure vein, which has a dip of 32° to the north. The original workings of the Montezuma consist of an open pit 60 feet in length and 80 feet in depth, extending across the entire breast of the vein, which is 25 feet from wall to wall at this point. The ore is cerussite (lead carbonate) and anglesite (lead sulphate), carrying from 60% to 65% of lead and from 1 ounce to 10 ounces of silver. Some galena is encountered in kidneys in the carbonate and anglesite. Farther west along the vein are three shafts, 30 feet, 80 feet and 105 feet deep, respectively. The accompanying illustration shows the dumps of the shafts.

The formation is similar to that at the Vulture mine, a schist which is found throughout the entire Vulture district, and in which are found all of the gold and silver-lead veins of that district.

Within a short time this property will again become a silver-lead producer. There are but few lead producing properties at present in the Territory, and there are fewer still known that are near railroads. Maricopa county is one of the coming lead-producing counties of the Territory.

Montezuma Lead Mine, Vulture District, Arizona.

Hand Sorting vs. Milling.

The Arlington mine at Erie, B. C., is an irregular vein in a slate formation. The vein has a slight dip to the west, and sometimes lies conformably with the slates and sometimes cutting across them, says the Canadian Mining Review. The slate formation is much broken and contorted, and there are layers of porphyry sometimes following the bedding of the slates and sometimes cutting across them at various angles and with different strikes. The ore consists of mixed sulphides of iron, lead and zinc, and the gold values vary greatly. Sometimes values as high as nineteen ounces gold per ton in the mine car samples occur where the ore contains a larger proportion of zinc sulphides. The vein varies from a few inches to as much as 25 inches in thickness, but the sulphides are always in separate and distinct layers or bunches free from the surrounding vein matter, and the remaining vein matter contains practically no value. This fact of the ore being separate from the vein matter has an important effect on the question of hand sorting or milling, as also the fact that

concentration only increases the value of the ore about 10%—that is, the clean ore shipped averaged $49.35 per ton, while the concentrates averaged $54.66 (assay value).

During the fifteen months from March, 1901, to May, 1902, a concentrator and tramway were built and the mine was worked as a concentrating proposition, the whole width of the vein being broken in the stopes and put through the concentrator, a portion of the clean ore being sorted by hand and sent direct to the smelter.

From September, 1901, to May, 1902, when the mill was running steadily and doing the best work, the results were as follows:

Tons milled		8,630.5
Concentrates produced		1,183
Gross assay value of ore milled	Gold	$94,504 00
	Silver	7,767.45
Gross smelter value of concentrates	Gold	54,088 00
	Silver	3,418.05
Percentage of recovery	Gold	57.9
	Silver	44.0
Average value of tailings per ton in gold and silver		5.93
Ratio of ore milled to concentrates produced, 7.3 to 1.		

Leslie Hill took charge of the property on April 1, 1902, and closed down the mill on May 14, as soon as the ore in hand had been milled. The mine at that time was gutted. The former manager and foreman stated that the mine was worked out and could not be operated further without loss. Previous to March, 1901, a large amount of development work had been done and the ore body developed and its limits apparently determined. All this ore body which was developed, and which was much larger than any ore body subsequently found, had been stoped out and the ore gouged out wherever it was sufficiently rich to put through the mill. It was evident that the mill could not be run any longer, and, in fact, it was as hard looking a proposition as one could run up against. An examination convinced Mr. Hill that it was a mistake to attempt to concentrate such ore. Mixed sulphides containing iron, lead and zinc are difficut to concentrate, and, where the values are largely in the lead and zinc, cannot be concentrated without considerable loss, even in the best of mills, whereas in a cheap plant such as the Arlington mill the loss was ruinously high. Concentration did not materially increase the value of the ore, so that there was no great saving in cost of transportation and smelting. The streaks and bunches of ore were defined, separate, and generally free from the vein filling, so that a large amount of waste material was being broken down and put through the mill out of which nothing was gained. The vein was nearly horizontal and very irregular, sometimes forming hollows, so that the cost of mucking was excessive, as the ore had to be moved by hand, and sometimes thrown up as much as 7 or 8 feet with a shovel. The roof being flat and disturbed, the stopes required filling in to make them safe. Taking all these facts into consideration, it was apparent that the proper method of mining this ore was by careful mining and sorting at the face. This plan was adopted and the mine at once paid its way. In fact, the ore which had been left behind as not good enough for the mill uot only paid for extraction, but in addition paid for the development work necessary to open up further ore shoots, and the mine has been worked at a profit ever since. It is sometimes necessary to break down a great width of veiu for a few inches of clean ore, but the vein filling is soft and can be broken down first and then the cleau ore taken out with the gad, or with light shots, and the saviug effected by filling back the stopes, instead of mucking out a large quantity, more than makes up for the expense of sorting.

When the mill was erected the only ore body which could be calculated on was the body already blocked out, and if that would not pay for the mill there was nothing to justify its erection. As a matter of fact, this ore body turned out in stoping much better than was anticipated, and yet the ore extracted and milled did not pay for the erection of the mill and tramway, even though all cost of mining was charged against the clean ore, and nothing against the milled. If the milling ore had simply been thrown on the dump as waste, a large saving would have been effected for the company.

It is not often that a direct comparison can be made between the results of different methods of mining. The following statements will show the results in this case of the two methods, concentrating and hand sorting at the face:

FOR FIFTEEN MONTHS—FROM MARCH 1, 1901, TO MAY 31, 1902.

Ore and concentrates shipped, tons	2,322.7
Net smelter value	$93,804.22
Cost of mining and shipping	83,589.67
Profit over mine cost	$10,214.55

The gross profit equals 10.9% of the net smelter returns Average net smelter value per ton, $40.39. Additional sums expended on capital accounts:

March 1, 1901, to June 1, 1901	$17,737.22	
June 1, 1901, to June 1, 1902	15,462.75	
Gross profit above		$10,214.55
Mess house profit, fifteen months		1,979.50
Net deficit		21,005.80
	$33,199.97	$33,199 85

FOR TWELVE MONTHS—JUNE 1, 1902, TO MAY 31, 1903.

Quantity shipped, tons	1,157.6
Net smelter value	$44,298.78
Total cost of mining and shipping	28,207.20
Profit over mine cost	$16,082.58

Average net smelter value of ore, $38.26 per ton. The gross profit equals 36.3% of the net smelter value. Charged to capital account, nil.

COMPARISON OF COSTS, PER TON.

1901-2.		1902-3.	
Supplies	$ 2.46	Supplies	$ 1.45
Developing and stoping	9 88	Development	3.74
Surface and general expense	3.79	Stoping	8 71
Mucking	3 90	Surface and general expense	2 83
Timbering	1 50	Mucking	3 45
Hauling and shipping	2.60	Timbering	.34
		Hauling and shipping	3 03
Total	$24.13	Total	$23 55
Mill working	9.31		
Tram working	.53		
Assaying	.98		
Stores (for mill, etc.)	.85		
Total	$11.67		
Cost, 1901-2, per ton	35 80		
Cost, 1902-3, per ton	23.55		
Difference	$12.25		

PROFIT AND LOSS.

1901-2.

10.9% of $93,804.22 equals $10,214.67

1902-3.

6.3% of $44,298.78 equals $16,082.58

Estimated profit in 1901–2 if worked on same plan as in 1902–3:

36.3% of $93,804.22 equals	$34,050.93
Actual deficit in 1901–2	21,005.80
Total	$55,056.73

The latter sum is the actual loss to the company through the building of the mill and the adoption of the system of concentration. Of course, the plant is at the mine, but if sold the net sum realized would be very small.

Foundation Bolts for Steam Engines.

Where a light cap stone is used, or where uo stone at all is provided, a type of bolt illustrated in Fig. 1

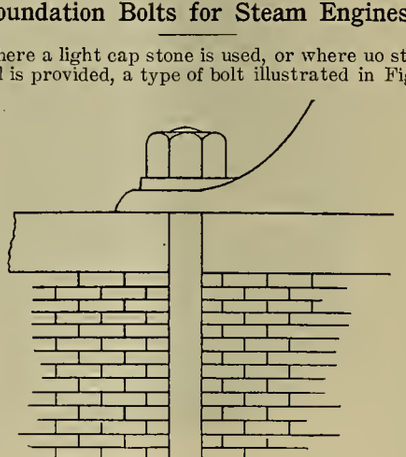

FIG. 1.

is sometimes used, writes W. H. Wakeman in Electricity. It consists of an ordinary bolt, except that it has no head, because it is easier and cheaper to put the end of it into a forge fire, heat it and bend it

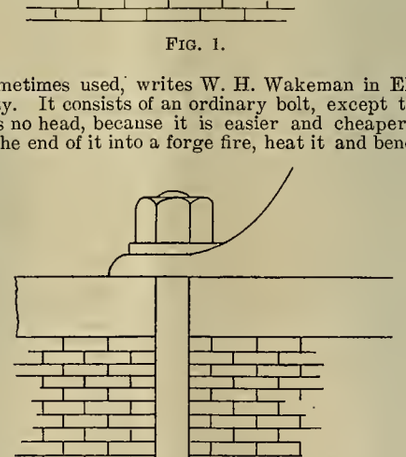

FIG. 2.

at right angles than to weld on a head, and, furthermore, some engineers can do the bending act who cannot make a good weld. Perhaps this is no discredit to them, as an engineer is uot supposed to be a blacksmith.

If care is exercised in building this into the brick wall so that it will have a good bearing it may give satisfaction in some cases, but it is not recommended. It is what may be termed an "unmechanical contrivance" at best, for the strain cannot come fairly upon it, as a consideration of its design will show. It is possible to make the bolt come up flush with the top of the nut, or a little above it, as shown, but if the feat is accomplished it is due to good luck more than to good management, for such a bolt will always yield some when the nut is tightened, and there is no rule or formula for determining the exact amount so that allowance can be made for it.

Fig. 2 illustrates a slight improvemeut, as the lower end of bolt is bent around a piece of iron, and this form of construction brings a straight pull on the bolt.

Of course this cannot turn when an attempt is made to turn the nut, neither can the form shown in Fig. 1, which is a desirable feature, but special care should be taken when building the foundation to have the bricks immediately above the horizontal part so laid that a good bearing will be provided when leverage applied to the nut gives a strong upward pull on the bolt.

Some engineers prefer to have their fonndation bolts located in pipes much larger than the bolts, but this idea is not recommended for either of the foregoing kinds, as it is much better to build them solidly into the masonry, if they must be used at all.

In this connectiou it is well to call attention to the fact that a foundation bolt very seldom resists a shearing strain directly, as it is employed to clamp the frame to the foundation, thus bringing a tensile stress upon it.

Fig. 3 shows a form of bolt that is extensively

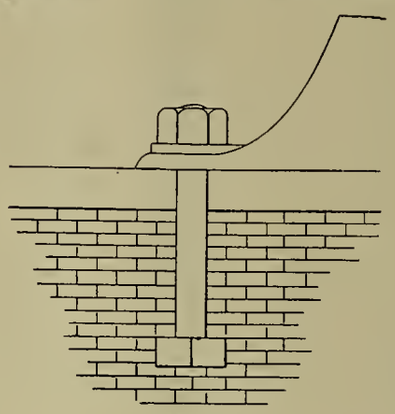

FIG. 3.

used. It has a large square head firmly welded to the bolt. Care is exercised to build the head solidly into the brickwork, so that the bricks above it may afford a good hold, while those at the sides prevent it from turning in case the nut does not turn easily.

It is not a good idea to use a pipe on a bolt of this kind, as it is better to have the bricks in close contact with it as above mentioned. The idea of using a pipe in this connection is but a makeshift at best, as the only object is to allow the bolt to be moved to come into the hole in the frame when it is lowered over it. This, of course, is all very well when care is not exercised iu locating the bolts, but theu there is no law against putting the bolts where they belong.

There are undoubtedly some brick masons who are competent to locate foundation bolts where they belong, but the majority of them are very careless, as they apparently think that if one is put anywhere within an inch or two of the designated place it will answer every purpose.

Wooden templates are furnished aud the bolts suspended in place, through holes bored in the templates, which is a good idea and should secure correct location of the bolts, but it is customary to remove the templates before the foundation is completed, then in some unaccountable manner, the tops of the bolts are moved out of place. This is not a theory but a condition to which I refer.

Bolts that are made according to the three previous illustrations are uot adjustable so far as height is concerned, therefore care must be taken to have them set high enough to give what is called a "full nut" when the work is finished. In other words, when the nut is screwed down tightly the bolt must be at least flush with top of nut.

Of course it is not a hard matter to cut off the bolt if it is too long (or rather, too high), but if not high enough it is difficult to make it right. My attention was recently called to this matter by seeing an engine on which some of the bolts projected about ½ inch above the engine frame, therefore it is necessary to do much chipping in order to get the nuts on far enough to hold, making an expensive and unsatisfactory job, simply because the template was not set high enough to bring the bolts up where they belong. The hole in the top of nut where the end of bolt should be, may be filled with putty and nicely painted, or a nickel-plated cover may hide the defect, but such a makeshift does not remedy the evil, except in outward appearance.

THE annual convention of Canadian mining engineers and mine managers will be held under the auspices of the Canadian Mining Institute in the King Edward Hotel, Toronto, on March 2, 3, 4, 1904.

Table Showing Weight of Cast Steel.

The following gives the weight in pounds of a lineal foot of round, octagon and square steel:

Size in Inches.	Round.	Octagon.	Square.
1/16	.010	.011	.013
1/8	.042	.044	.053
3/16	.094	.099	.120
1/4	.168	.177	.214
5/16	.262	.277	.334
3/8	.378	.398	.481
7/16	.514	.542	.655
1/2	.671	.708	.855
9/16	.850	.896	1.082
5/8	1.049	1.107	1.336
11/16	1.270	1.339	1.616
3/4	1.511	1.594	1.924
13/16	1.773	1.870	2.258
7/8	2.056	2.169	2.618
15/16	2.361	2.490	3.006
1	2.686	2.833	3.420
1 1/8	3.399	3.585	4.328
1 1/4	4.197	4.427	5.344
1 3/8	5.078	5.356	6.466
1 1/2	6.044	6.374	7.695
1 5/8	7.093	7.481	9.031
1 3/4	8.226	8.674	10.474
1 7/8	9.443	9.960	12.023
2	10.744	11.332	13.680
2 1/4	12.129	12.793	15.443
2 1/4	13.598	14.343	17.314
2 3/8	15.151	15.981	19.291
2 1/2	16.79	17.71	21.37
2 5/8	18.51	19.52	23.56
2 3/4	20.31	21.42	25.86
2 7/8	22.20	23.41	28.27
3	24.17	25.50	30.78
3 1/8	26.23	27.66	33.40
3 1/4	28.37	29.92	36.12
3 3/8	30.59	32.27	38.95
3 1/2	32.90	34.70	41.89
3 5/8	35.29	37.23	44.94
3 3/4	37.77	39.84	48.09
3 7/8	40.33	42.54	51.35
4	42.97	45.33	54.72
4 1/4	48.51	51.17	61.77
4 1/2	54.39	57.37	69.25
4 3/4	60.60	63.92	77.16
5	67.15	70.83	85.50
5 1/4	74.03	78.08	94.26

8	171.90	181.32	218.88
9	217.57	229.48	277.02
10	268.60	283.31	342.00
11	325.01	342.80	413.82
12	386.79	407.97	492.48

ONE of the interesting engineering feats of the past few years is the construction of the new bridge across the East river from New York to Williamsburg which was dedicated and thrown open to the public December 19. It is 7200 feet long, 1211 feet longer than the Brooklyn bridge, and cost $20,000,000, against $14,750,000 for the Brooklyn structure. It is double decked and carries two roadways, two trolley tracks, two promenades, two bicycle tracks, and a central space with two tracks for the L Road cars. The towers are 333 feet from high water, and the whole construction is of steel.

Mechanical vs. Natural Draft.

The question of draft in a manufacturing establishment, mining plant, or at any place where steam making is carried on, is often an important consideration in construction and first cost. The initial cost of a mechanical draft apparatus, breeching, fan, engine and stack is less than the first cost of a chimney. With natural draft, there is a large loss of heat, with a consequent waste, and it is estimated that the efficiency of steam, when used to create draft artificially, does not exceed 2% of the steaming capacity and is often lower than that. With natural draft, the temperature of the flue gases should not be lower than 600°, and it is known that between 600° and 700° F. the maximum results are obtained. With mechanical draft, the temperature of the flue gases need not necessarily be high, so far as related to the intensity of the draft, and this insures the highest efficiency of the fuel economizers, which utilize the waste heat of gases when installed with mechanical draft plants. The draft may be so regulated, with mechanical draft, that all the carbon of the fuel will be burned to carbonic acid gas, giving out 14,500 heat units for each pound of carbon burned. Mechanical draft is largely used in the anthracite districts, where large quantities of culm are available, and is an indespensable adjunct of mechanical stokers. It is claimed that mechanical draft results in a material increase in the capacity of the steam plant without increasing boiler plant. It makes it possible to burn lower and cheaper grades of coal, saves fuel and prevents smoke, and it has come to be recognized as an essential feature of the best modern boiler practice. The smoke seen issuing from stacks is largely of unburned particles of carbon, which, mixed with the gases from the furnace, is blown away into the air—a direct waste of fuel. This, it is claimed by the manufacturers of the mechanical draft apparatus here illustrated—the Buffalo Forge Co. of Buffalo, N. Y.—is obviated by the use of their devices. Fig. 1 illustrates the induced draft plant of the United Electric Co. of Hoboken, N. J. The fans and housing that are made by the Buffalo Forge Co. differ in design, according to the conditions under which they are to operate. Fig. 2 represents a Buffalo steel plate, left-hand top, horizontal discharge pulley fan, with steel housing. They are built right or left hand and to deliver air in the following forms: Bottom horizontal, top horizontal,- upblast and down-blast, and in any desired size. Fig. 3 illustrates a left-hand up-blast discharge steel plate fan, 80 inches in diameter, with overhung blast wheel.

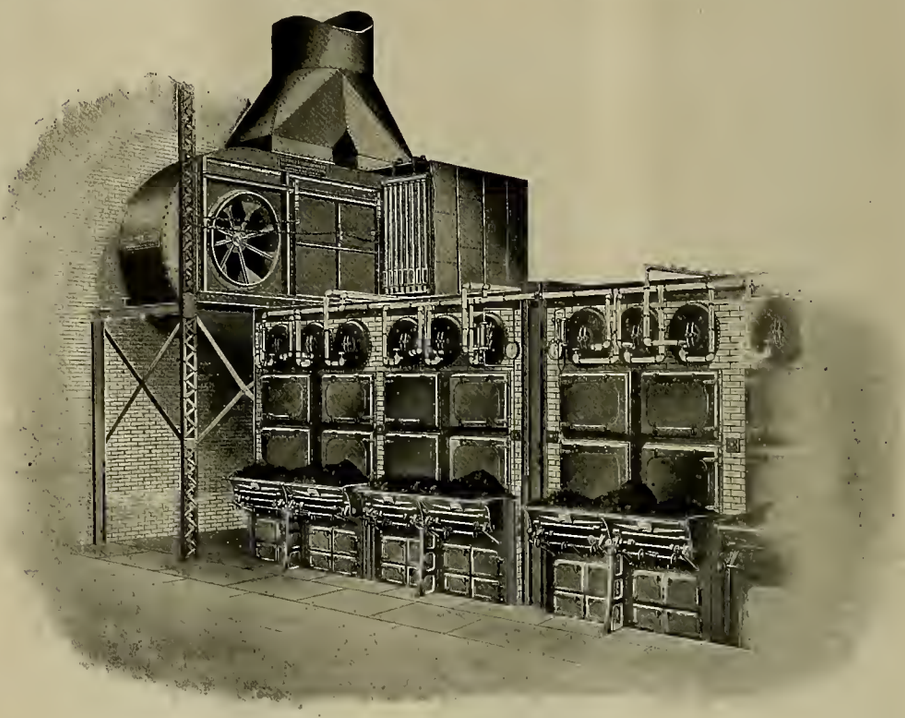

Fig. 1.—Induced Draft Plant–Horizontal Fans.

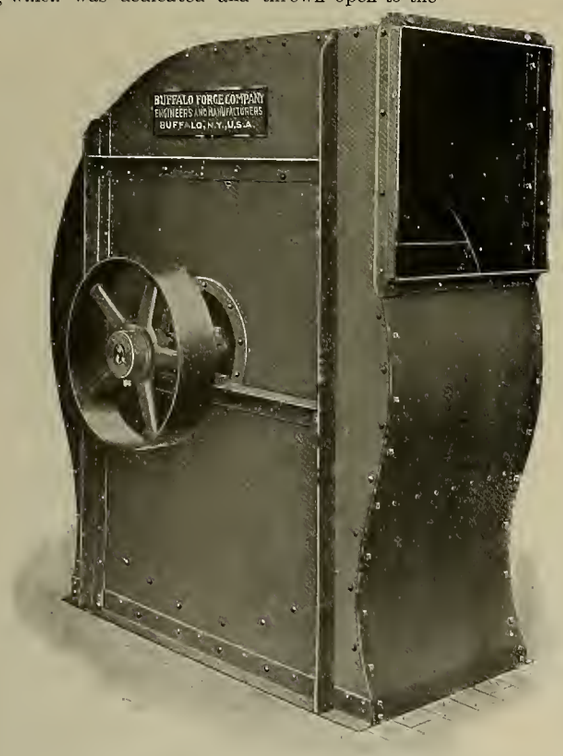

Fig. 2.—Left-Hand, Top Horizontal Discharge, Pulley Fan.

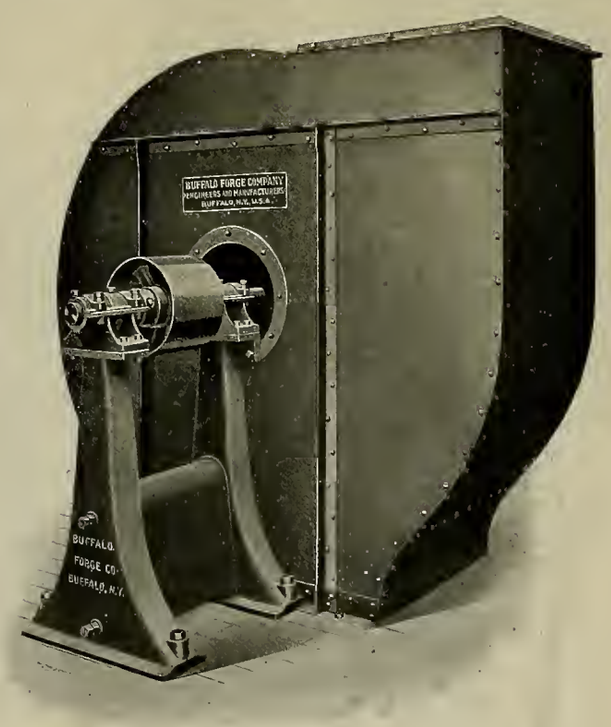

Fig. 3.—Left-Hand, Up-Blast Discharge, Steel Plate Pulley Fan.

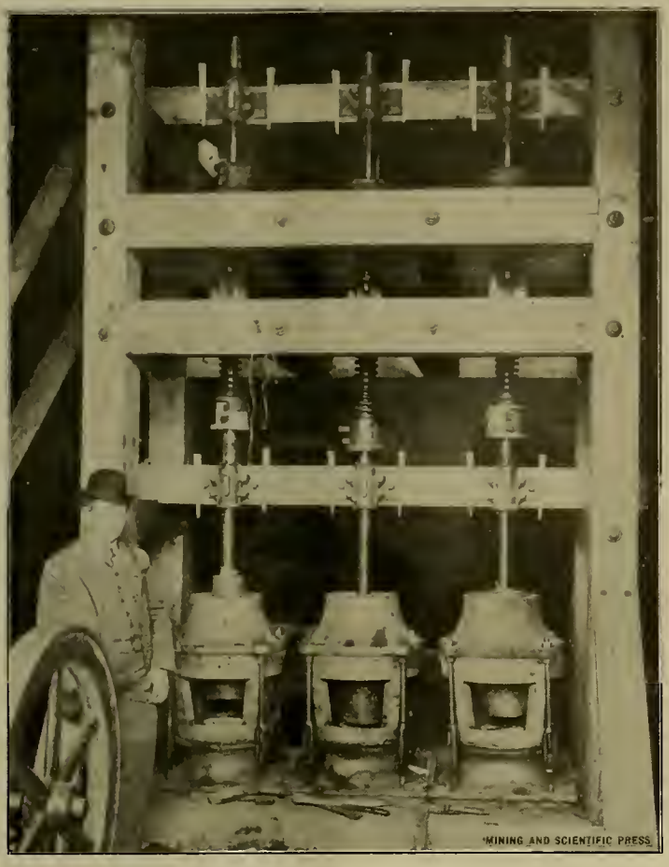
A Novel Quartz Mill.

The gravity stamp is one of the oldest as well as the most widely used means for reducing metal-bearing rock to a fine state of division for the purpose of extracting the metal contained in the ore. The gravity stamp is so simple a device that inventive genius has endeavored to find something better, or at least more efficient for the amount of power expended in crushing the rock, and thus more economical. This effort has led to the invention of a multitude of devices, including steam and pneumatic stamps, rolls, rotary mills (improvements on the arrastra), pulverizers of many types, and various other forms of rock crushing machinery. One of the latest and most interesting of these numerous types of ore mills is the Richards mill, herewith illustrated. In general appearance it is not unlike the single mortar gravity stamp mill, but in manner of operating it varies materially. The engraving shows three of the individual mortars arranged in a battery. The screens being removed show the stamps within the mortars. The stem is secured to a boss-head in the same manner as in the ordinary mill, and the shank of the shoe is fitted with wooden wedges into the lower end of the boss in the usual way. Guides similar to those in gravity mills may be employed, and the battery frame is similar. The mortar block is also of the usual type, and to it the mortar is securely bolted by means of the turn buckles shown in the engraving. The mortar is in three pieces—the square base, the central circular portion, and the top or cover. Thus far the Richards mill is not very unlike any gravity stamp mill, but the operation of the stamps is novel. It is actuated by a crank shaft, driven by a belt from an engine (or other means of power). The three accompanying sketches show the manner in which the mill works. The crank shaft operates a rocker arm, which raises and drops the stamp with a certain amount of "play." The "sliding block," shown in the central part of the front view of the battery, is held firmly, but not rigidly, in place by the spiral springs shown in the figures. This arrangement permits each stamp to be raised and dropped at any speed between 100 and 225 drops per minute. When running at a speed of 162 drops the maker estimates the stamp, which weighs about 750 pounds, strikes a blow equal to 2500 pounds, with one-third the power required to run an ordinary gravity stamp. Three stamps are run by means of a 4-inch belt. There is an adjustment for taking up the wear of shoe and die. The particular features claimed for this mill are: Low power required to operate; rapid drop of stamps; large screen area, and impingement of pulp from the center outward equally in all directions against the circular screen, with consequent large capacity. The above described mill is in operation and can be seen at 124 Fremont street, San Francisco, Cal.



The Richards Rapid Drop Stamp Mill.

Testing Ores for Cyanide Treatment.

NUMBER III.—CONCLUDED.

Written for the MINING AND SCIENTIFIC PRESS by R. STUART BROWNE.

C. TIME OF LEACHING.—In this series of experiments the size of the ore remains the same; the solution is the one chosen from the last work, but the time of treatment is variable. Some attempt must be made now to imitate the conditions of actual work as regards the volume of solution used. A total of 800 c.c. for 500 grams of ore would be a little high, but is near enough for this work. In regular mill work it is customary to use at least two solutions of different strength, the weaker one usually being about one-half the strength of the strong one. Therefore a second solution should be prepared of one-half the strength of the one already chosen for the strong. It is a difficult matter to at once determine the proper ratio of weak and strong solution, and the time of contact of each. This can be done only after the general form of treatment has been outlined. In this experiment it is best to adopt the emperical rule of equal volume of each, and equal time of contact.

The five samples in the percolators are now leached for periods varying from four to eight days with 400 c.c. of strong solution and an equal amount of weak. For example, the first one is leached for two days with strong, two days with weak, and then washed. The second is given two and one-half days with each solution and then washed, and so on with the others. As the time of leaching is extended the rate of percolation is decreased. It is a difficult matter to ad-

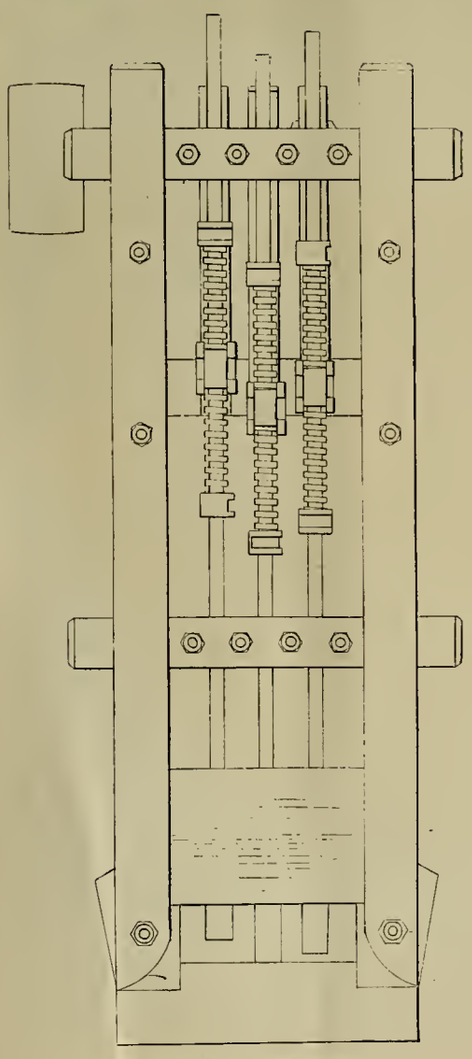


Fig. 1.—Front View.

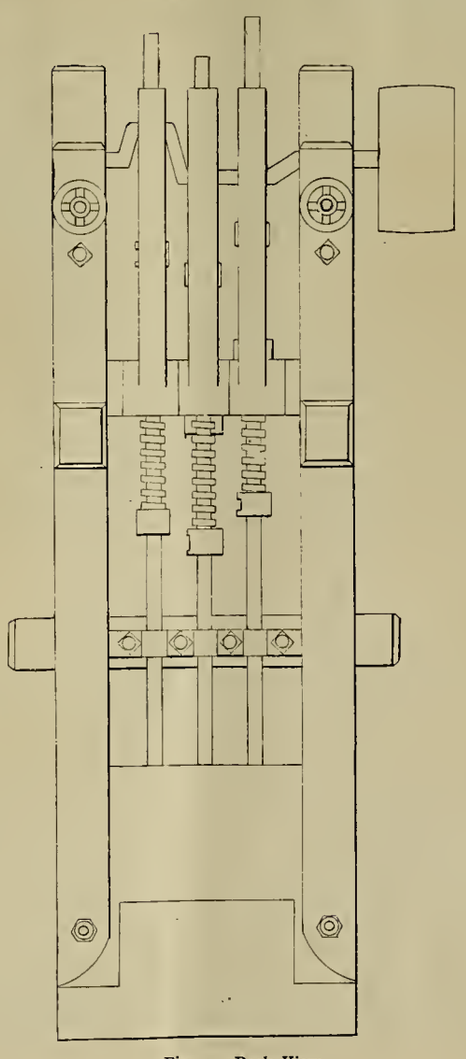

Fig. 2.—Back View.

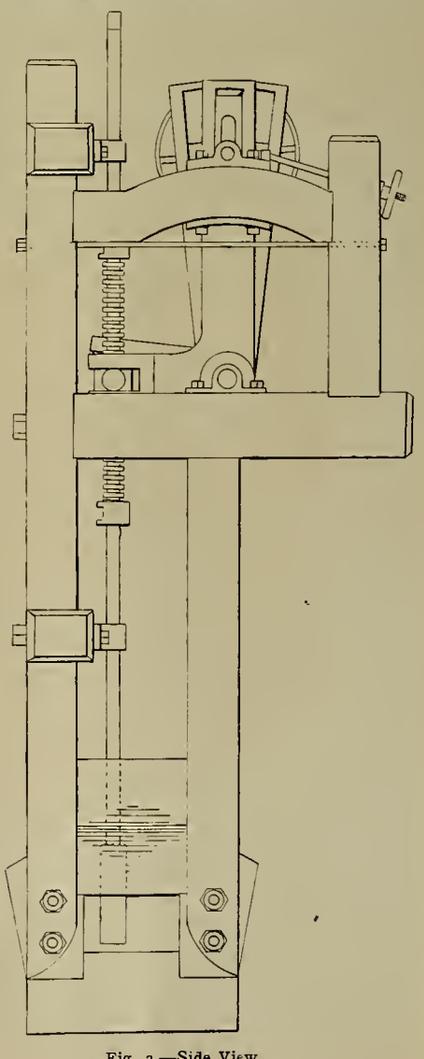

Fig. 3.—Side View.

just the clamp so that a given amount will drain off in a certain time. I have found it best to adjust the clamp as near as possible for the delivery of the required amount of solution for each tweuty-four hours, and if the amount is delivered before the time is up, to shut it off until the beginning of the next period. A graduated flask should be used to catch the solution. As soon as these tests are completed a close idea can be formed as to the probable treatment necessary for large scale work. If it is thought that the leaching can be done in less than four days, the experiments should be made to establish the fact; and likewise, if it is thought that more than eight days are goiug to be required, then extend the experiments to include twelve days. Au ore that requires longer time would hardly pay to treat by this process.

We will suppose, however, that the ore is well adapted for cyanide treatment and that a satifactory extractiou cau be secured in six days.

D. RATIO OF SOLUTION OF ORE.—A series of experiments must now be made to determine the amount of solution to use, and the proportiou of weak and strong. The work can be done systematically by using different volumes and then varyiug the proportion of the two solutions. But this takes up too much time. The chemist should be able to judge uow the best treatmeut to give, and therefore, instead of continuing the work along on systematic lines, he should assume a form of treatment and test it in the percolators. It is best to run a number at the same time, but with slight modifications in each. The general features, such as mesh, strength of strong solution and time, would remain the same, but the other features would vary slightly. When these results are tabulated the work is practically completed, and it only remains to make a final test on a larger scale. Generally, laboratories are not equipped for handling big samples, but 500 pounds can be manipulated easily, and the results would be sufficiently accurate to judge the behavior of a large charge. In my own laboratory I use for these tests large tubs thoroughly soaked with paraffine paint, so as to prevent any absorption of solution. The wooden filter frame is likewise protected. The filter cloth is made from heavy muslin and a new one is used in each test. For couveying the solution ¾-inch iron pipes are used. They should be arranged so that they can be readily taken out and cleaued. Unless these precautions are taken the solutions will be coutaminated from some previous test, or else there will be a loss from absorption. I attach a great deal of importance to the results from the solution assays, for they represent something that is capable of accurate measurement and sampling. Not only this; the extraction for each day can only be determined through them. For these reasons it is very important that everything possible should be done to eliminate any possible source of error.

Before making this fiual experiment the ore should be thoroughly mixed and sampled on a large canvas mat, and likewise after the leaching is finished. The exact weight of dry ore used in the experiment should be noted. Other details, such as the rate of flow, streugth of solution as it comes off, the amount of gold and silver dissolved each day, must be also determined and recorded. The consumption of cyanide can be calculated from the data of this test. In making the report the figures should be based on the treatment of one tou of dry ore.

Iu making these experiments the following hints will be of value:

Use C. P. potassium cyanide. The commercial cyanide contains both sodium aud potassium, and it is difficult to find its real strength.

Make up the solutions in large quantities, so that the strength is uniform in every percolator.

Never use a solution twice. Keep the solutions that drain off in separate bottles, and properly labeled, with number of experiment, date, volume, strength aud value. At the end take samples from each, assay and use as a check on the total extraction.

Having determined the mesh, crush up a lot to this size. It saves sampling.

Work systematically and tabulate results.

Remember that the cyanide chemist endeavors to obtaiu the maximum extraction with the coarsest mesh, minimum amount of time, weakest solution, and lowest cost. The combination that produces the greatest profit is the desired process.

In the foregoing experiments we have endeavored to find a process by which we cau treat the ore by straight percolation. Now, it may happen, either from chemical or physical causes, that the ore cannot be treated in this way. It may require a preliminary treatment, such as roasting, concentration, removal of the slime, etc. The mere fact that the preliminary investigation has shown a poor extraction is not sufficient grounds for rejecting the process altogether. The cyanide process is very elastic and it is rare, indeed, that it cannot be applied in some modified form. Of course, the question of cost of treatment must enter largely into the matter. No process is a success unless it is so financially.

Owing to its non-permeability, the treatment of slimes has always been one of considerable difficulty. But the introduction of the filter press and the method of agitation aud decantatiou has in a great measure overcome the trouble, and to-day large accumulations of slimes are being treated at a satistory profit. In experimenting in the laboratory with this class of material, apparatus different from that used in percolation is necessary. Slime tests are much simpler than percolation, for the reason that the mesh is already determined, the time of treatmeut and volume of solution are fixed within close limits, and the gold and silver are already soluble, as a general rule. The chemist will, therefore, make some comparative tests to determine the strength of solution and fix the time of agitation. The solution used will vary from one to three parts by weight for each part of dry slimes. The amount required for displacement must be determined from the value of the solution, the rate of settling, etc. Small tubs paiuted with paraffine paint are well adapted for these tests. Some form of agitator must be employed, preferably the same kiu d that will be used in the large plant. This may be either compressed air-pumps or some form of mechanical stirrer. In all agitation plants the time of extraction is influenced in a marked way by the opportunity given for the solutious to aerate themselves. For laboratory tests to be representative, similar conditions must prevail as in large plants.

Within a comparatively recent time it has been found that a great many sulphide and telluride ores will give a high extraction without roasting if the ore is slimed. When the chemist comes across such an ore it would be well to carry out some experimeuts along this line before recommending roasting. A great many mills produce low-grade concentrates that could be treated more cheaply by this process than shipment to a smelter or chlorination works. The material gathered from the canvas table is particularly well adapted to this form of treatment.

It would be well to come back, now, and consider the question of how far the results of the laboratory work may be taken as a criterion of the work of a large plant. The results of a test ou a 500-pound sample are, I think, very closely approximate to the work of a mill. If anything, they are a trifle high. One reason for this is that the mill has to use impure solutions, while in the laboratory only pure ones are used. Some chemists, however, have claimed that au old mill solution has greater power than a new one of equal strength. If this is so, then the accuracy of laboratory work is much increased, for then the errors would be more compensating. Another factor favoring higher results in the laboratory is the shallow depth of the charges. In the percolator or tub the air can more easily penetrate to the bottom of the charge than in a large vat. The pressure of plenty of oxygen means a more rapid solution of the gold and probably a higher extraction. Another thiug frequently overlooked is the method of washing the ore. In the laboratory the pulp is washed much cleaner than would be done in a mill, and this would give slightly higher results. This can, of course, be remedied by regulating the wash water. The possible difference in the physical condition of the ore is an important matter, aud it is difficult to just see how it will influence the work.

Ore crushed in a laboratory will be more granular thau that which comes from any mill. Inasmuch as finer grinding favors higher extractiou, it would seem that we could expect a higher extraction in the mill. But increased depth of charges packs the material more, and it may be that the fines will become less pervious to the solution and thus offset this advantage. Weathered tailings always contain twigs, roots and similar foreign matter, and the slimes which always constitute a part of the dump are caked. In my own experience, covering work in a good many laboratories, I have yet to see the chemist who does not pick out the sticks and carefully break up the lumps of slime. It may be good practice and it may not be. One thiug is certain, however: It favors higher extraction in the laboratory. These are the principal reasons why the laboratory work is apt to give higher returns than the mill. The amount of error is not very great, however, and I think the results may be taken for all practical purposes as representative.

The Tinplate Industry.

Sir John Jeukins has coutributed au article on the Welsh tin industry to the Westminster Gazette, in which he says: The discovery of the method of sheet iron rolling established the iudustry in Moumouthshire iu 1778, and tinplate making remained practically a Welsh monopoly until 1891, when the McKinley tariff came into force. In 1862, 1,000,434 boxes of 112 tiuned steel plates, 20x14 inches, weighing 108 pounds each, were exported; more thau half of these went to the United States. In 1882 5,300,000 boxes were exported, of which the United States took 430,000. By 1889 the respective figures were 8,600,000 aud 670,000. Iucreasing demand in the Uuited States was due to the development of the food canning industry and the adoption of terne plates for roofing purposes. The McKinley tariff threatened a tax of 10s ou a box which could be sold at 9s f. o. b. Swansea, and that caused feverish activity in Wales. The average price of coke plates —13s 7d at Liverpool aud $4.37 at New York in 1889 —went up to $5.45 in 1891. Under pressure the tariff was then reduced from 22 to 12 cents per pound, but it was raised again to 15 ceuts iu 1897. There are now 320 tinplate mills in the United States, employing 15,000 people. But Wales still supplies tin plates to the United States for exportation of packages, and as the exports are allowed a rebate of 99%, it follows that the Standard Oil Co. and others are receiving a subsidy for using Welsh plates or export packages. The immediate effect of the McKinley tariff on the Welsh mills was disastrous. Mills had to shut down temporarily, and if it had not been for the previous boom there would have been more failures. The men suffered great distress, however. In 1893, 12,560 were out of work, against 15,500 regularly employed. But by 1899 an improvement had been effected—412 works, against 500 in 1891, were at work again. The exports to the other countries were pushed; new industries have developed, and the home demand for tin plates has almost doubled iu ten years—from 2,500,000 boxes in 1892 to 4,500,000 in 1902.

Gold Deposits of New Zealand.*

NUMBER III.—CONCLUDED.

Written by ALEXANDER MCKAY.

GOLDFIELDS OF THE NORTHERN DISTRICT OF WESTLAND.—At one time it was thought that the granitic rocks of Mount Rangitoto were gold bearing. On this mountain a vein of iron pyrites contained about one-fifth of its bulk of galena, which was prospected as a silver ore, and this also proved to be auriferous. Neither the silver nor the gold was in quantity sufficient to pay for the working of the deposit, and the report that gold was preseut in the adjacent granite, on being investigated, did not lead to miuing in that rock, although it was said the preseuce of minute quautities of gold was proved. The Cedar Creek reefs, and some reefs on the west slopes of Mount Greenlaud are yet to be proved payable; aud of the different reefs known to exist in the mountains, from the gorge of the Hokitika to Jackson's, on the Teremakau, all of them that have beeu prospected have failed to indicate a paying character, and the attempt to work such reefs has beeu abandoned.

GOLDFIELDS OF THE REEFTON DISTRICT.—The gold obtained from quartz very considerably exceeds in amount and value the alluvial gold obtained in the same district.

UPPER BULLER GOLDFIELDS.—It is only on Lyell creek that quartz mines are being worked within this area. The Owen reefs, though for a time assiduously prospected, are now abandoned.

WAIMANGAROA AND MOKIHINUI GOLDFIELDS.—Reefs of a payable character occur on both of these fields, but up to the present the yield of gold from them has been small, and much less than the amount of alluvial obtained in the same district.

GOLDFIELDS OF THE NORTHWEST OF NELSON.—Within the bounds of Collingwood county there are only two quartz mines being worked at the present time. These are situated in the mountains between the Aorere valley and the west coast south of West Wanganui iulet. The production of gold from these mines up to the present time has not been great, though recent results have been encouraging. Quartz mining in the Aorere valley has ceased. The yield of reef gold from all parts of the district has been little compared with the amount of alluvial gold that has been obtained from the same field.

TERAWHITI GOLDFIELD, WELLINGTON.—The amount of gold obtained from this field was not great. Alluvial and reef gold was obtained in nearly equal proportions, and the alluvial has, without doubt, been derived from the reefs, whether of pure quartz or from a peculiar brecciated deposit that consists mainly of country rock cemented by quartz.

GOLDFIELDS OF THE AUCKLAND PROVINCIAL DISTRICT.—Practically the whole of the gold from these fields has been the result of mining in quartz, and the almost total absence of alluvial gold from the Hauraki goldfields is a peculiar feature that has already been referred to.

CONCLUSIONS.—From the preceding it will be appareut that in eastern and central Otago the prospects favor a more energetic development of alluvial mining in that district. The search for quartz reefs need not, however, be discouraged or abandoned, for it will be a surprising thing if it should prove that hitherto the only payable auriferous reefs have been found, and it cannot be supposed that in every case these are already exhausted. Improvements, more especially in the method of dealing with refractory ores, should enable the reworking of many of the mines now lying idle on the Carrick range. In the past these mines paid to work till reaching the limit of circulatiug waters, when, from the presence of increasing quantities of sulphides and arsenides, the ores became refractory, and with the then means and appliances they ceased to yield a profit to the shareholders or owuers. The same may be said of other parts of the district where large lodes exist, and no doubt the future will provide the means of again workiug a uumber of mines that are now idle.

The progress of miniug in Otago for some time recently has showu that for many years to come the chief and largest returns of gold must be derived

*Abstract Report of Government Geologist.

from the extensive alluvial cement deposits of various ages that are spread over the country.

The richer and more accessible superficial deposits are being exhausted. Such deposits supplied almost all the gold during the first three years after the discovery at Gabriel's gully. In deep and wet ground the ordinary methods of mining failed to reach the gold, or reached it at such cost that its extraction was no longer profitable. Hence extensive and costly dams, head and tail races, diversion of streams, and the building of dredgers to scoop up the gold of the river beds.

Improvements in the construction of dredgers and the discovery that by means of these machines profitable returns were to be obtained elsewhere than from the beds of the Molyneux and other large streams, so stimulated this form of the industry that for two or three years there was a boom in dredging over the whole of Otago and the west coast of the South island. As a rule, dredging can be applied only to modern deposits or the superficial exposures of beds of greater age. Yet the field for dredging in Otago and Southland is extensive, much of which is virgin ground that could not be successfully worked by any of the different hydraulic methods. Dredging in the greater part deals only with the most modern gravels of the district, but there are places where older rocks are also being worked by means of dredgers.

Gravels of Pleistocene and Pliocene age are worked at many places by hydraulic sluicing at heights varying from sea level up to 2500 feet above the sea, and by the same process the older quartz drifts are worked at an elevation of 4000 feet above sea level.

The Maori bottom (Pliocene) and the younger and older quartz drifts are at places much disturbed, and the auriferous bands are sometimes in a vertical position.

At Preservation inlet and on the Wilson river goldfield further discoveries of quartz lodes may be expected in the Silurian rocks of that district. At the same time alluvial mining should not be neglected, as there are possibilities in both directions of an improved condition of mining on this field.

In northern Westland and along the southern side of the Grey valley every effort should be made to develop alluvial mining, quartz mining being less promising.

In the Reefton district, including the eastern side of the Little Grey watershed, something should be done in the way of prospecting the older gravels of the district and the quartz cements that lie at the base of the coal bearing series.

The southern part of the Paparoa range, where this is formed of Carboniferous rocks and of the same in character as the Reefton auriferous rocks, merits further prospecting for auriferous quartz reefs.

North of the Buller to Collingwood and Cape Farewell, wherever there are indications of quartz lodes, the country should be prospected for auriferous reefs; and prospecting for fresh deposits of auriferous alluvial and cement deposits should also be carried on.

The hope of the Marlborough goldfields appears to lie in the development of its reefs, despite the fact that in the past the results have not been such as could be wished.

On the Hauraki goldfields of Cape Colville peninsula much prospecting was done between the years 1895 and 1899, which did not result as anticipated. Nevertheless, prospecting should be continued, as it cannot very well be that all the payable lodes of the peninsula should have been discovered and sufficiently tested.

Method of Treatment of Low-Grade Copper Ores.*

Written by J. J. MUIR.

In following out the writer's investigations on the treatment of low-grade copper ores, he has ventured to present an improved method of forced extraction, which will fulfill the conditions required in treating these ore bodies at a commercial profit.

A great bulk of this class of ore exists in various parts of Australia and Tasmania, and in no conceivable way can it be profitably dealt with by a smelting operation. After arriving at this conclusion, the writer turned his attention in an experimental way to the various methods in general use, with a view of ascertaining what percentage of copper extraction could be obtained by them under the existing conditions, and also at what cost. In such methods as natural leaching, salt roast, ferrous sulphate and the principles laid down in the Hunt-Douglas process, the results at which the writer arrived fully established the claims of all of them to a good extraction under the conditions necessary for their operation.

It is, however, essential in proposing a method of treating these ores that the commercial side of the problem should be equally as successful and prominent as the metallurgical one. It is in the satisfactory adjustment of these two opposing factors that a solution of this subject will be found, and, as a consequence, increased activity in the handling of these classes of ore.

After a patient review of the foregoing results and conclusions, it appeared to the writer that the lines on which investigation must be carried out in reconciling the two factors referred to would be a careful consideration of the chemical conditions of the ores themselves.

The chief obstacle to be overcome is the avoidance of the necessity of transporting large quantities of chemical re-agents to isolated positions for a treatment process of the ores. The first cost of these re-agents in addition to their excessive transport charges in most cases renders it impossible to work out a satisfactory result. In conjunction with this difficulty, it is also necessary to arrive at a high extraction of the copper, and, moreover, to show a speed in the work that will compare with that obtained in a smelting operation. The lines of investigation followed by the writer were, therefore, narrowed down considerably, and the issue on which a successful result would be arrived at clearly defined.

In considering the ores to be treated the writer will confine himself to those typical of the West Coast of Tasmania, as these ores through their high silica contents have baffled the smelter from the financial point of view. The writer does not suggest that these ores cannot be smelted, but that the operation results in a loss, when importing the necessary fluxes and fuels. The following is a typical analysis of these ores: Silica, 48.00%; copper, 4.56%; iron, 13.29%; sulphur, 12.60%; alumina, 12.90; zinc, 1.17%; manganese, 1.26%; lead, 1.40%; magnesia, 3.40%; and oxygen and loss by ignition, 1.42%.

It will be seen from the conditions that these ores contain a large amount of sulphur, and, moreover, that by a judicious selection of a small proportion of the ores, as they leave the mine, the sulphur contents can be considerably increased. This is the main condition by means of which the writer proceeded to work out a method for their profitable treatment.

OPERATIONS AT THE MINE.—In extracting the ore from the mine by any of the usual systems, the aim should be to roughly and cheaply throw out the richer sulphides; to the extent of from 10% to 12% of the bulk of the ore treated. This smaller proportion is reserved for separate treatment, and the conversion of its sulphur contents into sulphur dioxide (SO_2) fumes, and in turn their conversion into sulphurous acid (H_2SO_3) by solution in water. The main bulk of the ore then goes forward to the regular plant.

PREPARATION OF THE ORE (MAIN BULK).—The ore is first reduced to such a degree of fineness as the operator may find necessary in order to expose the small sulphide particles to the oxidizing flame of the reverberatory calciner. The machinery employed for this purpose can be adapted by any individual operator to suit himself. The writer would employ a Gates crusher followed by rolls, the schistose ores being soft and easily dealt with.

CALCINATION OF THE ORE.—In this connection the writer would like to mention that the type of reverberatory calciner described by Dr. Peters in his Modern Copper Smelting is well adapted for this process. The stage to which the calcination must be carried is the first important consideration in dealing successfully with these ores. Provided that the last of the sulphides, as such, have been converted, it is a matter of no moment what proportion the residual oxides and sulphates bear one to the other, and the charges can be drawn at that stage. The sulphates being easily soluble, the writer provides for the attack on the oxides only.

FORCED LEACHING OF THE ORE.—The calcined ore is then transferred to the wooden leaching vats (fitted with filter bottoms), being discharged gradually and hot from the furnace onto the sulphurous acid (H_2SO_3) plus water solution, derived from the ore that has been separately treated. The best mixing proportion is 200 gallons of solution to one ton of the roasted ore. The ore is covered and the temperature considerably raised by the hot ore. The hot-air blast, described under the separate treatment, is then turned on, and the temperature is further raised. The copper oxides are attacked very rapidly by the sulphurous acid, following the equation $CuO + H_2SO_3 = CuSO_3 + H_2O$, and the extraction is completed in a very short time.

The hot oxygen of the blast tends to oxidize the surplus sulphurous acid (H_2SO_3) into sulphuric acid (H_2SO_4) and this is an advantage. The chilling effect of the cold solution on the hot air is greatly obviated by the initial raising of the temperature with the hot ore, and it will be found that a rapid extraction temperature is quickly reached.

PRECIPITATING THE COPPER.—The strong copper solution is then run into the precipitating vats onto bars of pig iron and the temperature is again raised for a quick precipitation. One wash water will recover the soluble copper in the dampness of the ore.

SEPARATE TREATMENT OF THE SELECTED PORTION OF THE ORES.—This portion, being higher in sulphur contents than the main portion of the ore body, will be used for making the sulphurous acid necessary for leaching the whole of the ores. It is essential that as little of the sulphur contained in these ores should go to waste as possible, and it is, therefore, necessary in the arrangement of plant to provide for this. Pyrites, heated in a closed muffle or retort, does not give up the whole of its sulphur; but this result can be minimized by admitting a light pressure of compressed air, sufficient to overcome the head, due to the depth to which the fume discharge pipe is immersed. The hot air coil is arranged in the furnace chamber of the muffle, so as to utilize the heat from the same fuel and minimize cost. Both the hot air and fume-discharge pipes are led into the leaching vats, and the water charge is thus prepared for the reception of the hot ore from the calciner. The pressure behind both of these pipes is, of course, regulated to suit the mechanical conditions.

By the adjustment of these conditions to the ores under treatment, and according to the detailed plant which the writer has designed, a rate and cost of production can be obtained that will successfully deal with these ores.

COST OF TREATMENT PER TON OF CRUDE ORE.—Under the conditions prevailing where these ores exist, the cost of treatment would be as follows per ton of crude ore:

	s.	d.
Crushing schistose ores	5	0
Reverberatory roast	3	0
Labor on leaching vats	0	6
Hot air	0	6
Sulphurous-acid water	2	0
Pig iron	2	0
Total	14	0

In addition to this, mining and delivery of the ore to the works by self-acting tram would cost 10s, or, say, a total of 24s per ton of crude ore. Against this, a deduction of 4s could be safely made on the copper recovery from the muffle-roasted ores, leaving everything well on the conservative side.

Under average conditions, therefore, the total charges against the ore would be £1 per ton, and the precipitated copper will range in assay value from 70% to 80%. It would be the final product of this process, and the writer feels it unnecessary to follow it further on its course to refined copper. There is a ready market for this high-grade product, so that returns and final adjustments can be made at short notice.

CONCLUSION.—After a long and careful consideration of this subject, the writer has arrived at the conclusion that this process will fulfill the conditions necessary for the successful treatment of these ores. The action is rapid, continuous and complete, and the costs of running can be further minimized in many directions, not detailed in the general outline of this paper.

In operation it is advisable to have an excess of sulphurous acid (H_2SO_3) in the solution, over and above what is necessary for the conversion of the copper oxides into their sulphites, and a day's experience of any ore will disclose the best conditions to an operator. A minor advantage of this process is that it is not based upon any nicely-drawn chemical equations, with the corollary of high cost of supervision.

*Abstract Trans. Inst. M. E., Eng.

In discussion, E. D. Peters wrote that J. J. Muir now described the results that he had obtained in the wet treatment of copper ores since his former communication. Mr. Muir is evidently going through the same difficult and laborious investigations that have been undertaken for the same purpose in the United States during the past twenty-five years, and that have resulted in the two Hunt-Douglas methods, the McNeill process, the Van Arsdale process and others. They nearly all of them depend upon the utilization of the sulphur in the ore, or derived from extraneous ores, as a solvent for the copper—the sulphur being first burned to sulphurous acid gas, and the gas being converted into sulphuric acid by various means. Mr. Muir finds that he can obtain from the sulphurous acid derived from a careful roasting of a very moderate amount of pyrites a sufficient quantity of sulphuric acid to rapidly dissolve the oxidized copper contained in the roasted ore. He effects this result by forcing a blast of heated air through an aqueous solution of sulphurous acid while in contact with the ore in the leaching vats. The copper is then precipitated by pig iron in the usual manner.

G. D. Van Arsdale proposes a still greater economy in this direction, though he had not tried it on a working scale at the time of writing the above article. Mr. Van Arsdale finds that a heated solution of cupric solution, when saturated with sulphurous acid gas under pressure, yields a considerable proportion of its dissolved metal in the shape of a precipitate of metallic copper, while free sulphuric acid is formed. The solution is then used to dissolve fresh ore, the operation thus being continuous. He gives the following formulæ in explanation of this interesting reaction:

(1) $3\,CuSO_4 + 3\,SO_2 + 4\,H_2O = Cu_2SO_3, CuSO_3$ (cupro-cupric sulphite) $+ 4\,H_2SO_4$.

The sulphite precipitate then usually reacts further with the free acid formed thus:

(2) $Cu_2SO_3, CuSO_3 + 4\,H_2SO_4 = Cu + 2\,CuSO_4 + 2\,H_2SO_4 + 2\,SO_2 + 2\,H_2O$.

Mr. Peters figures that Mr. Muir has already found, in common with all investigators in the United States, that there is little difficulty in selecting a method that will dissolve the copper from these low-grade quartzose ores. The sulphur in the ore will furnish the solvent required, and the ore can be easily and cheaply roasted in such a manner as to reu-

der 90% or more of its copper contents soluble in quite dilute acids.

The main difficulties lie in carrying out the operation rapidly and economically on a large scale, and are for the most part mechanical. Much money and labor has in this country been expended in devising apparatus that shall burn the crushed pyrites thoroughly and with an exactly regulated admissiou of air, so that a sufficiently concentrated sulphurous acid gas can be obtained from an ore low in sulphur. Still greater difficulties have been encouutered in the leaching of the ore, wooden tanks having proved unsuitable for these acid solutions, and, fiually, iron vats lined with heavy lead have been employed. The presence of slimes, produced both by the ore itself and by ferric salts precipitated from the solution, has beeu very troublesome, and at some works has called for an extensive installation of filter presses.

How Radium is Obtained.

Written for the MINING AND SCIENTIFIC PRESS by A. SELWYN-BROWN, E. M.

Few chemical discoveries iu recent years have been so valuable, or have created keener interest, thau the brilliaut investigations that led up to the separation of radium and the examination of many of its chemical, physical and physiological properties. Already the knowledge gained by investigating its action upon different substances has revolutionized our knowledge of the constitution of matter, aud altered many important scientific theories; and in the near future more remarkable results are promised.

The present value of radium is $2,721,000 per pouud, and it is by far the most expensive of all the metals. Even at this extraordinary price the demand far exceeds the supply, and there is consequently a fine incentive to search for radium ores. But such a search is difficult. All the ores of radium have not been determined, and most prospectors are unable to have their minerals tested for the metal. Very little has been published on the chemistry of the radium compounds, aud a rapid and simple reaction to test the presence of radium in a mineral or ore is wanting. However, a knowledge of the present means of isolating the metal is of importance, and a little further experimentiug may lead to the discovery of short and suitable methods of analysis, and to the finding of radium iu greater abuudance than is at present thought of.

ORES OF RADIUM.—Origiually radium was obtained from the uranium mineral pitchblende, and at the present time uranium minerals furnish most of the metal. But the latest researches show that radium occurs in association with numerous other minerals, and dispersed in many localities throughout the world. The following minerals are distiuctly radioactive, and, although radium has not beeu proveu to be in all of them, their radio-active properties are most probably due to its presence:

Uranium.	Æschynite.
Pitchblende.	Fergusonite.
Cleveite.	Samarskite.
Alunite.	Niobite.
Autunite.	Tantalite.
Sipylite.	Polycrase.
Compounds of Thorium	Euxenite.
Orangite.	Columbite.
Monazite.	Carnotite.
Xenotime.	

It would also appear that radium is present in mauy bismuth, tellurium, zinc, barium, stroutium, calcium and cadmium minerals.

CURRIE'S EXTRACTION PROCESS.—Prof. Currie obtains radium from pitchblende by an involved and tedious process. The ore is crushed fine aud roasted with the addition of carbouate of soda. The roasted ore is then washed and treated with dilute sulphuric acid. The sulphates thus obtained are couverted into carbonates by boiling with carbonate of soda. The carbouates are agaiu converted into sulphates. Radium sulphate is an exceedingly insoluble salt, and at this stage of the process it may easily be separated from the more readily soluble sulphates by filtratiou. The residue, containing radium, barium and several other sulphates, is then treated with dilute hydrochloric acid, which extracts polouium, actinium and a couple of other chlorides, and leaves radium aud barium sulphates. These are converted into carbonates by treatmeut with a strong boiling solution of sodium carbonate. The carbonates are theu dissolved in hydrochloric acid, aud precipitated again as sulphates by means of sulphuric acid. The sulphates are purified to a further exteut by a repetition of the above treatments with hydrochloric and sulphuric acids, and ultimately the radium chloride is separated from the barium chloride by the slow process of fractional crystallization. A ton of pitchbleude by this meaus usually yields about fifteen pouuds of the combined chlorides of barium and radium.

GIESEL'S PROCESS.—F. Giesel, a German chemist and experimenter, prepares radium by treating barium, strontium and calcium with bromic acid, after the ores have been purified as described in the Currie process. The mixed bromides are then subjected to fractional crystallization. The first crystallization, when carefully carried out, is generally sufficieut to remove the strontium and calcium. After about eight or nine more crystallizations of the barium and radium bromide mixture from distilled water, the separation of the more readily soluble radium bromide is easily obtained. During these operations the flame coloration of a Bunsen burner may be conveniently utilized to indicate the progress of the purification; or fractional precipitatiou by ammonium carbouate may be employed. The radium carbonate is precipitated last. Pure anhydrous radium bromide produced in this manner exhibits a bluish phosphorescence when freshly prepared, but in the course of a couple of days the salt discolors and all signs of phosphorescence disappear.

ELECTROLYTIC PROCESS.—It has beeu found that radio-active substances can be obtaiued from bismuth and analogous miuerals by electrolytic means. It is thus possible to obtain thin films of radium from minute quantities of radium in any ore. The metals are first dissolved from the ores by any suitable means, and then submitted to electrolysis at ordinary temperatures. The cathode requires to be made of pure bismuth, and carbon or any other suitable anode may be employed. The requisite current strength has to be found by experiment; but it is usually fairly low. This process is comparatively simple and more rapid than the purely chemical processes, and is likely to be shortly improved so that it may easily be employed in every assay office.

Dry Concentration.

Written for the MINING AND SCIENTIFIC PRESS.

Though the concentration of ores in the United States has not reached the development and importauce that it has in Europe, it is now making rapid advauces yearly. The advantages of conceutration were not fully realized until it became necessary to mine the low-grade ores, or those far from transportation by railroad. Millions of dollars are locked up in such ores with no profitable means of release but some form of conceutration. A large proportion of these ores are in either cold or dry regions; hence the importance of dry concentration.

Prejudice has probably had a great deal to do with retarding many improvements in the business of mining, notwithstanding the fact that pure prejudice uever made a dollar for any one, and that careful thought and experiment are the only elements that yield profits. One of the main troubles in the concentration of ore has been that it has not been generally understood that the actual operation of conceutrating by any particular device is only one-half the problem.

The preparation of the ore before it goes to the concentrator is even more important than the operation of concentration itself, for if the ore is not properly prepared, no satisfactory concentration can be obtained, no matter how expert aud vigilant the operator may be.

Iu the preparation of ore for concentration the slime, or, as it becomes the dust questiou in dry crushing, is one of the most important in the process. The production of undue fines is serious in almost any process, and especially so to either wet or dry concentration. In wet concentration the fines float off with the water. In dry concentration they tend to clog the ore strata, so that it is difficult for the air to act freely.

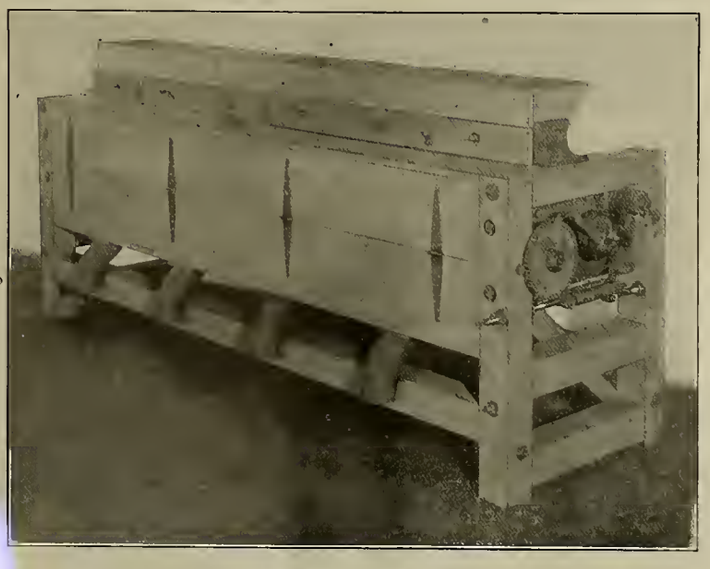
Jaw breakers that produce a uniform product by a crushing action combined with a series of rolls have been found to furnish a crushed product having a small amount of fines. Both the breakers and the rolls crush the ore but once, as the ore passes directly through them. There is no crushing of material already fine enough and no grinding of particle on particle.

The rolls should not be set too closely together. They should be arranged in series of three or more, accordiug to the nature of ore, each set of rolls crushing a little finer than the precediug oue and the product of each screened after it passes through, only the over-size going to the next roll. The rolls should be run but little faster than the ore is dropping from the hopper to them, which is less than 16 feet per secoud. If the roll runs faster than this it is doing no work, as it is ruuning ahead of the delivery, aud, wheu the ore does strike, the increased crushing shock from the high speed produces undue fines. The wear and tear on the roll is far greater, power is needlessly eaten up, aud all to uo purpose.

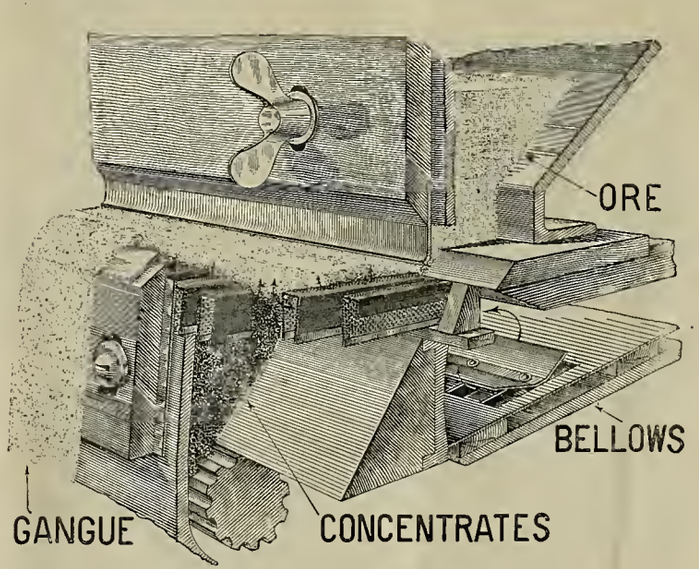
A dry coucentrator recently developed by the Krom Machine Works, 170 Broadway, New York City, is shown herewith. The ore is delivered without sizing to the hopper of the machine, from which it is fed by gravity to the table of the machine. This table is composed of a number of inverted tubes formed of wire cloth aud placed ¼-inch apart. As the ore flows from the hopper on the table, 600 sharp air blows per minute are projected through the tubes and into the ore from an oscillating fan, the effect of which is to rapidly raise and drop the mass of ore, lifting the lighter mineral more than the heavy and superposing it on the heavier mineral, which sinks between the tubes to a chamber below, where it is removed by a take-off roller as fast as may be required. The lighter portion of the ore at the top is pushed over the tailiug gate by the outflowing ore from the hopper.

The tailings are the only means of escape for values in this process, so that an inspection of them shows if any loss is taking place. When the machine is once set to the ore the concentration goes on automatically. Floating dust is saved by an exhaust fan aud pipes connecting concentrators, roll housing, bins, screens, etc., with a series of long canvas bags, from which the dust can be collected if valuable for treatment. By this arrangement the awful dust of a dry crushing mill is avoided, converting an uninhabitable mill into a habitable one.

Dry concentration is designed to furuish conceutrates ready for smelting, cyaniding, leaching or any further treatment.



Dry Pneumatic Concentrator.



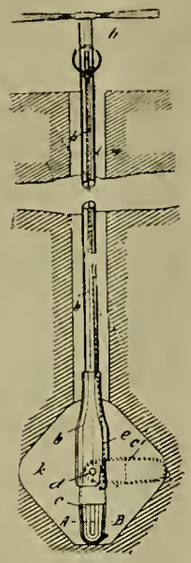
Sectional View of Dry Ore Concentrator.

Mining and Metallurgical Patents.

PATENTS ISSUED JANUARY 5, 1904.

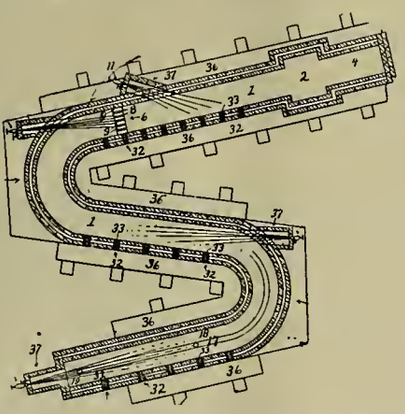
Specially Reported and Illustrated for the MINING AND SCIENTIFIC PRESS.

DEVICE FOR THE CLEANING OF EXPLOSION CHAMBERS.—No. 748,034; F. Anschutz, Neunkirchen, near Trier, Germany.



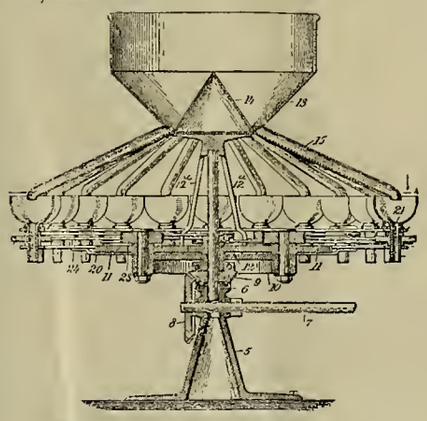
Device for cleaning of explosion chambers at ends of horizontal bore holes, comprising in combination tube with handle at upper end, spoon pivoted to enlarged bottom end of tube, traction wire fixed at one end to spoon before and beside pivot of same, longitudinal slot at upper end of tube near handle for passage of upper end of traction wire and ring fixed to upper end of traction wire.

SMELTING FURNACE.—No. 748,561; E. Riveroll, Los Angeles, Cal.



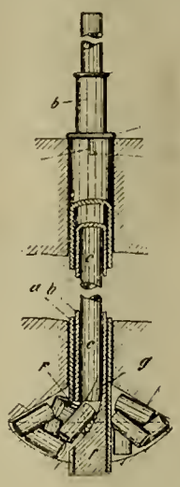
In smelting furnace, inclined sinuous chamber, upper end of which is gradually tapering its entire length in cross sectional area and provided with means for feeding ore thereto, and plurality of hydrocarbon burners communicating with chambers along its length.

CONCENTRATOR.—No. 749,104; L. F. Schoenfeldt, Denver, Colo.



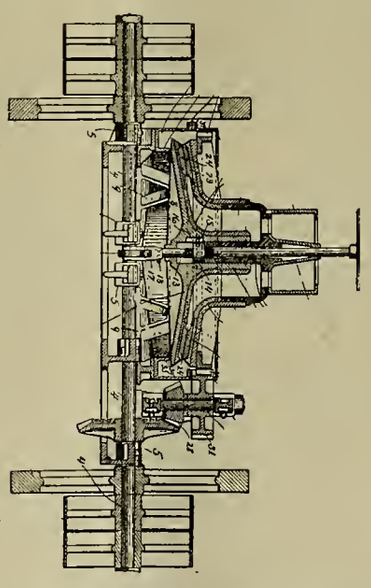
A concentrator comprising series of cups, rotary part carrying cups, outlet tubes extending from bottoms of cups and having rotative bearings in rotary part, means for imparting rotary motion to cups, a hopper and conveyors for material leading from hopper to several cups.

APPARATUS FOR THE LOADING OF EXPLOSION CHAMBERS.—No. 748,035; F. Anschutz, Neunkirchen, Germany.



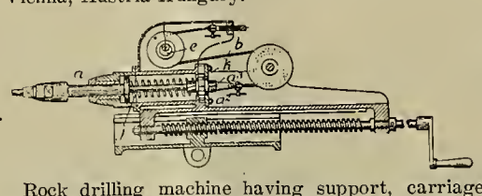
Apparatus for loading with cartridges explosion chambers at ends of bore holes, comprising in combination, tube of diameter to fit bore hole, lateral opening at bottom end of tube, flange at upper end of tube, longitudinal slot through flange and upper end of tube wall, second tube of diameter to fit outer tube, metal piece closing inner tube at bottom end, curved upper surface of metal piece, lateral opening in wall of inner tube close to lower edge of curved upper surface of metal piece, nipple at upper end of inner tube adapted to engage longitudinal slot of outer tube, flange at upper end of inner tube, rod fitting inner tube, curved surface at bottom end of rod correspouding to curved surface of metal piece in inner tube.

QUARTZ MILL.—No. 748,867; C. J. Hodge, Houghton, Mich.



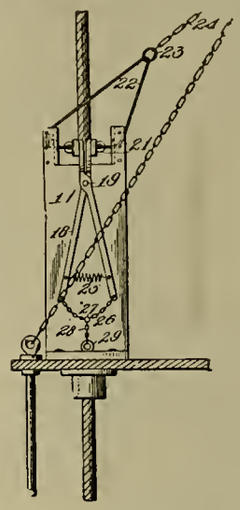
A quartz mill comprising a lower fixed cone having upwardly extending elougated tubular neck, driving shaft, stem passed through tubular neck and supported on driving shaft, upper revolving cone having gear ring, dome shaped upper member fitting within revolving cone and having depending hollow spindle supported on stem within tubular neck, inner and outer plates secured to fixed and revolving cones respectively aud providing bell shaped space between them, hardened plates set in inner and outer plates and formed with annular pocket between them, lower and upper casings within which cones are located.

ROCK DRILLING MACHINE.—No. 748,712; A. Fauck, Vienna, Austria-Hungary.



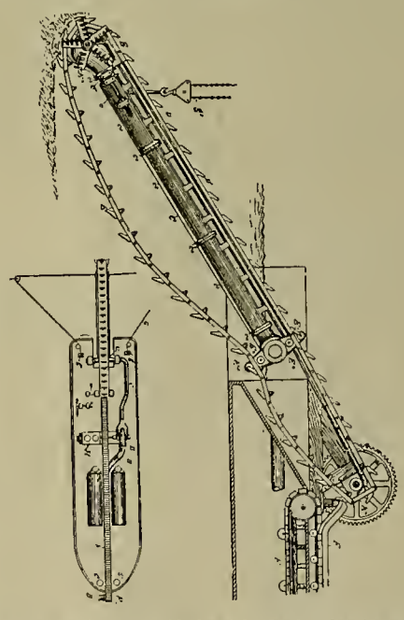
Rock drilling machine having support, carriage movable longitudinally thereon, means to move carriage, reciprocatory drill bar, driving shaft and pulley carried by carriage, spring to move drill bar in one direction, eccentric ou driving shaft, cord having ends conuected respectively to carriage and drill bar and having oppositely extended bights eugaging pulley and eccentric, and motor to drive shaft and carried by carriage.

SAFETY APPLIANCE FOR MINING HOISTS.—No. 748,962; J. Lewis, Sault Ste. Marie, Canada.



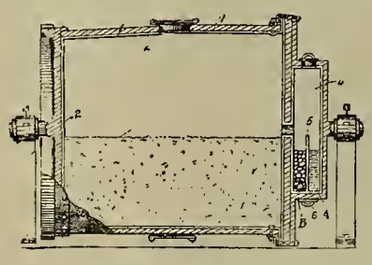
In safety device for hoisting apparatus, combinations with cage, of vertical guides between which cage travels, cable for raising and lowering cage, tongs arranged to grip guides and hold cage stationary, flexible connections between tongs and hoisting cable arranged to hold tongs inoperative while hoisting cable is taut, and means connected to cage and constructed to automatically cause tongs to clamp guides and prevent descent of cage when cable becomes slack.

DREDGING MACHINE.—No. 748,804; W. H. Smyth and A. R. Bowers, San Francisco, Cal.



A suction pipe provided with device having projections extending beyond its normal surface adapted to engage with and remove obstructions from mouth of pipe and mechanism to actuate device independent of water flow.

CHLORINATION BARREL.—No. 748,462; W. J. Armbruster, St. Louis, Mo.



Chlorination barrel having pulp chamber, and chlorine generating compartment carried thereby and rotatable, and in unobstructed communication therewith through one of ends of barrel, and freely discharging chlorine thercinto above surface of pulp.

Mining Summary.

SPECIALLY COMPILED AND REPORTED FOR THE MINING AND SCIENTIFIC PRESS.

The following table gives, in long tons, copper production of the world for the years 1901 and 1902, with estimates of 1903 outputs, reports H. J. Steveus in the Daily Mining Record. The final figures will not be secured for six months yet, in some cases:

Country.	1903.	1902.	1901.
United States	318,861	303,446	272,609
Spain and Portugal	51,000	49,790	53,621
Mexico	48,000	35,785	23,795
Chile	50,000	28,130	30,730
Japan	31,000	29,775	27,475
Germany	22,000	21,605	21,720
Canada	22,500	17,485	18,800
Austra asia	29,000	28,640	30,875
Peru	7,500	7,580	9,520
Russia	8,000	8,000	6,740
Cape Colony	4,500	4,450	6,400
Norway	5,000	4,565	3,375
Italy	3,500	3,370	3,000
Miscellaneous	8,500	7,895	7,282
Totals	589,361	551,316	515,992

ALASKA.

A third gusher is reportod struck in the Kayak oil fields. The flow was developed in one of the wells of the McKenzie-Mann Co., which is oporating, under bond, the holdings of the Alaska Dev. Co. The flow, whicb was struck in an oil sand at a depth of 900 feet, is said to have spurted 70 feet iuto the air.

ARIZONA.

Cochise County.

The pumps of the 700-foot level of the Tombstone Con. Co. shaft at Tombstone aro in operation. These pumps are duplicates of tbe station pump on the 200-foot level. The daily capacity of the station pumps is 2,500,000 gallons each, the lower pump draining tho incoming flow and sending the same to tbe reservoir on 600-foot level. From there the first duplex pumps continuo to lift to the surface. Since working the pumps on the 700-foot level, drifting has been started. Tbe inflow of water on the 700-foot is diminishing, according to the pumping record, says Manager W. F. Staunton. The company is arranging to sink the shaft to 1000 feet.

Gila County.

B. Gaylord of Los Angeles, Cal., and Boston, Mass., men havo for $200,000 bought the Taylor group of twelve claims and tbe Bird group of eight claims near Globe. The Taylor group is on Buffalo hill, running nortbeast, and adjoins mines of the United Globe, near the Old Dominion. Development on the Taylor group consists of a crosscut tunuel on the Bobby Burns, which has cut two veins at sballow depth, from which shipments of copper ore have been made. A shaft 100 feet deep on the Tip Top claim, sunk on tbe vein, shows in the bottom a ledge of iron oro. A 120-foot sbaft on the Tip Top No. 2 is in copper ore. The Bird group of eight claims adjoins the Big Johnny mine, the Iron Cap group, the Copper Hill and the Taylor group. Development on the Bird group consists of several prospect shafts, showing veins, and a shaft 185 feet in depth on the Bird claim, the ore carrying values in copper. Development work has been started on both groups by Gaylord.

Graham County.

Manager S. S. Campbell of the Chase Creek C. Co., operating near Cliftou, says work is progressing on their group, which consists of forty claims in a body betweeu tho Longfellow mine and the claims of tho New England Co. A tunnel bas been driven in 440 feet from Chase creek on one of the claims. This tunnel is the lowest in the camp, says the Standard, being 1200 feet lower than tho tunnel driven by tho Clifton Con. It is headed towards the New England claims, and if continued beneath them it will give them an outlet on Cbase creek and tap their ore bodies at a depth of 2000 feet.

The Shannon C. Co. near Clifton is adding 250 tons to the capacity of its concentrator, wbich will increaso the output of refined copper about 300,000 pounds per month, and make total capacity of works 14,000,000 pounds per annum. Necessary converter improvements will cost $25,000, and are expected to be completed by March 1.

E. Pergoli, of New York, has a bond on the Cuprite group of claims near Garfiold, near Moreuci.

Maricopa County.

(Special Correspondence).—C. Schellenbergor has men at work on a group of claims which he has located northeast of Hot Springs junction.——S. W. Haines is taking out free-milling oro from his mine near Buckeye. —— The Wickenburg smelter has suspended operations for an indefinite time. —— Hull & Duke will put men at work on their group near the Garcia mine. —— G. Francis is working men on his property in the Vulture district. Ore has been struck.

Phœnix, Jan. 11.

Mohave County.

The Yucca Cyanide M. & M. Co. is driving for the vein at the 480-foot level of tho San Francisco mine, says tho Kingman Miner. As soon as the vein is broken into and drifts started, work will be resumed in the shaft, which will be sunk to the 600-foot level.

Santa Cruz County.

The Happy Jack M. Co., operating in the Santa Rita mountains, is shipping high-grade ore.——In the Hardshell mine, near Harshaw, a drift is being run on the 325-foot level, from which a raise is being made. Botb drift and raise are in good ore. ——In the Hermosa mine, near Harshaw, the tunnel running to cut the ore body below tbe old workings is going ahead.

I. N. Curtis, manager of the Globe Exploration Co., says he is increasing development work on the Mowry mine, near Harshaw.——Proto Bros. are increasing operations upon their Abunduncia and Thessalia mines, on tbe west side of the Patagonia mountains, north from the Washington camp road, and are opening up ore.

Yavapai County.

G. Wood, manager of the Bed Rock M. Co., says operations on their holdings are expected to resume this month. This company owns five groups of patented claims in Hassayampa, Groom Creek and Lynx Creek districts, near Walker. Of these are the Dutchman, Golden Fleece, Mammoth and Midnight Test groups. The Dutchman is near the Mudhole. The Midnight Test is ¼ mile from the Home Rule mine, on Groom creok.

Machinery for the 10-stamp mill at tbe Hiddon Treasure group of mines, owned by tho Stark M. Co., on lower Turkey creek, 20 miles southeast of Prescott, is on the ground, says Superintendent W. W. Elliott. The mill building has been completed. Tho battery of two 60 H. P. boilers is also set up. Tbe process will be amalgamation and cyaniding. The cyaniding plant will bave a capacity of twenty-five tons daily. It is expected the entire plant will be in operation by Feb. 1st. The hoist is being set up, which has a capacity for sinking 1000 feet.

The Black Rock M. Co., operating near Constellation, reports work progressing. Superintendent J. K. Murphy is putting up buildiugs and has excavations for the mill completed. Machinery is on the ground, including a hoist for sinking the shaft, whicb is down 200 feet and will go to 500 feet.

CALIFORNIA.

Amador County.

(Special Correspondence).—G. G. Gates is experimenting with the tailings from the mill of the Fremont Con. (Fremont-Gover) G. M. Co., noar Drytown, preparatory to building a canvas plant.

Drytown, Jan. 13.

It is reported that T. Boyson of Plymouth has arranged to work the Illinois quartz mine near Plymouth.

A steam 2-stamp mill is being put up at the Climax mine in Clinton district, near Pinegrove, which is expected to handle twenty tons of rock a day. There are 100 tons of ore on the dump and 1000 tons blocked out in the mine, says the Dispatch.

At the Oneida mine, near Jackson, work continues. The mill is dropping fifty stamps, and ore is being taken from the various levels from the 1200-foot to the 2200-foot station. Development work is being done south from the 1200-foot station, but the principal work is being done north of the shaft, says the Dispatch.

At the Hendy mine, in the black slate belt north of Plymouth, the company is sinking from the 600-foot point to 1000 feet. At 700 feet a body of milling rock 18 feet wide is being developed. The 20-stamp mill is being put in ordor.

Butte County.

A. Brown of Stockton has options on 1200 acres of land near Bangor, 12 miles from Oroville. Brown agrees to begin prospecting within ninety days. This land includes the Blue Lead mine. The company proposes to run a tunnel for drainage and then drive drifts and raises from this main tunnel.

Calaveras County.

A. L. Fortman et al. bave bought the Spring Day quartz mine near Glencoe.—— C. W. Tryon has bought the Sunny South and Sunny Side quartz claims, near Augels.

The mining suit by J. H. Brotherton of Denver, Colo., involving tbe Royal Con. mine at Hodson, has been compromised and the suit dismissed by stipulation. Owing to a strike of the miners at tbe Royal, the mine was closed down and the strikers have been temporarily enjoined from interfering with the mine or the non-union men who have been secured to take the places of the strikers. The taking out of ore has been resumed and forty stamps are operating.

Operations are resuming in the Union copper mines at Copperopolis. For the past twelve years nothing has been done with tbe property, except to keep out water and prospecting for new ore bodies, says the Angels Record. During that time, however, the company bas been acquiring additional land, and it owns a strip 6 miles long extending on each side of the town north and south. F. L. Ames, Jr., of Boston, Mass., owner, has put men to work repairing the buildings. A French company is said to be negotiating for the property.

Contra Costa County.

G. B. Fredenburg of the Pacific Coast (Standard) Oil Co. at Point Richmoud is preparing to build a plant, auxiliary to tbe refinery, for manufacture of acids used in refining oil. Construction will begin tbis week. The capacity of the refinery is to be furtber enlarged.

Mooo County.

The repair work at the reservoir and power bouse having been completed the Standard Con. M. Co. at Bodie last week resumed operations in the mine and mill.

Nevada County.

The Mountaineer G. M. Co. of Nevada City bas been incorporated by J. Bender of Hamilton, Ohio, D. E. Morgan, F. Searls, J. C. Campbell of Nevada City, J. M. Duke, W. T. Farrer of San Francisco and G. M. Henderson of New York. The property consists of a consolidation of the Mountaineer, Walrath, Fortuna, Dodo, Live Yankee, Orleans and Orleans Extension, covering 3 miles along the road in a southerly direction from the Mountaineer. Manager Campbell has men unwatering tho Mountaineer aud clearing the 400-foot and 700-foot drifts south. He will drive the 400-foot level south through the group of claims, the most southerly of which it will tap at depth of 700 feet. It will be used as a drain tunnel and enable the company to handle the flow of water which in former years interfered with development.

Placer County.

N. J. Pierson, H. Wales and N. T. Collins have bought the Big Boulder mining claim, in Secret canyon on the American river, near Colfax.

Plumas Couoty.

A tunnel is being run on the Glazier mine, near Greenville, to tap the channel at the lower end of the claim. The tunnel is in 700 feet,. with three shifts at work. The channel has been worked on the upper end of the Glazier.——The Dunn mine, owned by Dunn Bros., is being oporated steadily. Tbe mill is crusbing fiftoen tons of ore per day.

T. J. Lamoureaux of Oakland, working quartz properties at Horseshoe Point on the North Fork, near Greenville, reports a 10-stamp mill will be built on the Horseshoe mine as soon as transportation facilities will permit, says the Independent.

Shasta County.

Near Lowden's Ranch, in the spring work will resume in dredge mining at Poker Bar, on Trinity river. The Poker Bar M. Co. bas operated a dredger at that place for several seasons. The company has been reorganized with J. D. Morse of San Francisco as president. A new boat will be built. The company has a ten years' lease on the Poker Bar ground. They also propose to build a dredger on the Lowden ground.

It is reported the Redding G. & C. Co. is preparing to build a 100-ton smelter 8 miles west of Redding for custom work. It will put in an electric plant near the smelter of 1000 H. P. capacity.

W. F. Snyder of Salt Lake City, Utah, manager of the Western Exploration Co. of Utab, controlling the Balaklala M. Co. copper mines at Kennett, says he is preparing to build a reduction plant at the mines. It is expected to be in operation before the end of the year.

Trinity Couoty.

At Lewiston, Superintendent J. W. Phillips of the White Cloud mine has cleaned up the old workings, preparatory to running a crosscut tunnel to tap the vein. The ledge matter in the White Cloud is said to have a width of 30 feet. ——E. H. Hugbes and T. Hancock have completed their reservoir and ditch and bave begun piping in their hydraulic mine in Jennings' gulch.——The Mooney Con. M. Co. will resume operations on its gravel property in Mooney gulch.—— There is considerable activity among tbe quartz mines in Eastman gulch. C. E. Goodyear and W. Richards have built a 2-stamp mill, which they will have in operation by Feb. 1st.

Tuolumne Couoty.

T. A. Piper of San Jose bas taken hold of the New York tunnel gravel mine in Jeffersonville section, near Jamestown, and has seven men at work cleaning out the tunuel preparatory to reopening the mine.

Work at the Mary Ellen mine will be resumed. The mine is on the main river, next to the Mohican mine, near Groveland. —— Electric drills are in use at the McAlpine mine and are said to be giving satisfaction. The buildings at the mine, as well as the underground workings, are lighted by electricity. Sinking and drifting are progressing.

The labor trouble at tbe App mine at Quartz has been settled and the mine started again. It is stated the management agrees to pay tbe miners tbe wages desired, but will not pay engineers as much as demanded.

J. Viera has bought the Kelly and Marshner mines, on the middle fork of Tuolumne river, 5 miles above Drew's bridge, near Carters, together with water rights belonging to both claims, consisting of 300 and 200 inches, respectively, with ditcbes.

Tbe Hoosac G. M. Co. bas bougbt the Nancy Lawton mine and millsite, on tbe south fork of the Stanislaus river, ½ mile abovo Deer Creek, near Columbia.

Tbere are being placed at the Horseshoe Bend mine, on the Stanislaus river, near Columbia, for tunnel work, an oil-burning engine, air compressor and machine drills.——Work has been resumed at the Hull mine, near Groveland, says Superintendent Froelich.

COLORADO.

(Special Correspondence). — Reports from different parts of the State indicate renewed activity in the mining industry in Colorado. In many of the smaller camps, especially, is sent word of good strikes being made. These reports are not confined to any one locality, but seem to extend to most of the mining sections.

The action of the militia in demanding the surrender of all firearms, as well as the enforcement of the vagrancy order in the Telluride and Cripple Creek districts, has provoked considerable discussion pro and con. Tbe "vag" order is to the effect that all men who have no visible means of support are considered vagrants and can be deported by the militia from the different camps. This order has been enforced extensively in the Telluride district. In Cripple Creek the Western Federation has asked tbe courts to enjoin the militia from carrying out the order, but the militia, so far, have refused to be enjoined, claiming that the civil authorities bave no voice in the matter; that the militia have full power to act as it deems best, and that they are not deporting men who are willing and ready to work, but are deporting the ones who will not work themselves or allow any one else to work.

Denvor, Jan. 11.

Chaffee County.

Tbe Vivandiere concentrating mill, near Salida, is nearing completion and will be put in operation Feb. 1st. The mill will have a daily capacity of fifty tons. C. T. Snedeker is superintendent.——The 4-foot body of ore found in the Hershberger tunnel on Cameron mountain is a gold-bearing hematite, and runs $6 per ton, says Superintendent Miller. He is driving the tunnel ahead.

Custer County.

The Dolomite mine, owned by the Custer M. & R. Co., west of Custer, will be opened up to the 200-foot level. The Elematah also will be opened up and shipments started. The Evening Star and Bryan, on North mountain, are showing mineral values.——G. White, superintendent of the Grand Rapids G. M. Co., is working men on its prospects. At the Dakota Bill and Valley mines the shaft bouse has been nailed up for the winter. With a view to having them milled, the dumps at the Humboldt have been sampled and are being tested.

Mineral County.

The output of the mines of Mineral county for 1903 is given by the Creede Candle as follows:

	1903.	1902.
Gold	$ 375,450	$ 102,813
Silver	2,905,983	3,420,553
Lead	1,501,800	717,336
Zinc	150,180	75,000
Totals	$4,933,413	$4,315,702

The output for the year was:

Month.	Tons.
January	5,283
February	5,788
March	7,072
April	5,715
May	5,645
June	5,711
July	5,636
August	6,396
September	6,891
October	6,914
November	7,039
December	5,674
Total	73,764

This, against the total tonnage for 1902 of 71,193 tons.

Cleghorn, Ewing & Weiss of Denver,

owning the Krutzer Sonata mine, near Creede, are preparing to increase development work this season.

Ouray County.

W. R. Kramer, manager of the Governor mine, in Mount Sneffels district, near Ouray, has let contract for additional development work, to consist of drifting on the vein and making a raise from the lower tunnel to the upper workings. The Governor has bodies of ore partially blocked out. Arrangements have been made to put in a 10-stamp mill in the spring.

San Miguel County.

During the past year the Tom Boy G. M. Co., near Telluride, crushed 80,000 tons of ore at its mills, from which was obtained approximate total of $740,000, including both gold and bullion concentrates. The bullion shipped amounted to 39,180 ounces, and the concentrates 6960 tons. The new 60-stamp mill is said to average 10,000 tons of ore per month, and the capacity of the Huntington mill is 4500 tons. Except at brief intervals the two mills have not been operated at the same time. The old mill is run on ore taken from the Tom Boy workings by leasers, the company treating the ore on a percentage plan. The estimated cost of mining, milling and treating the ore per ton, including all development expenses, is $5.80. The mine is 6 miles from a railroad, and all supplies and machinery must be transported from the shipping station in Telluride to the mine either by mule back or in wagons.

Teller County.

The lessees operating on the Proper mine in Poverty gulch, Cripple Creek, owned by Stratton's Cripple Creek M. and Dev. Co., are shipping ore.

A strike of high-grade ore 2 feet wide is reported made in one of the properties of the United Mines Co., under lease on Ironclad Hill, Cripple Creek. The United Mines Co. is controlled by Woods Bros. Their Gold Coin mine is said to be improving. Water is going down in the shaft.

IDAHO.

(Special Correspondence).—R. N. Bell, State Inspector of Mines, reports the total output of metals for Idaho for year 1903 as follows:

	Quantity.	Value.
Gold, fine ounces.....	92,938.42	$ 2,085,993.76
Silver, fine ounces.....	7,224,021.58	9,318,986.41
Lead, pounds.....	220,857,456.00	9,386,213.13
Copper, pounds..	2,524,000.00	336,954.00
Total value.....		$21,123,147 30

Gold at $20.67; Silver, $1.29; Lead, $4.25; Copper, $0.1335.

The Cœur d'Alene district of Shosbone county alone produced 213,520,000 pounds of lead and 5,750,000 ounces of silver; an increase in lead of 33% over the output of 1902.

Boise, Jan 10.

Boise County.

Manager V. Thorne is arranging to sink a shaft for development of the English company's quartz claims in Gambrinus district, near Idaho City. It will cut the John Henry ledge at depth of 500 feet on the dip and those of the other claims at greater depths.

Idaho County.

(Special Correspondence).—The Belle of Thunder Mountain M. & M. Co. of Pittsburg, Pa., C. D. Greenleaf president and E. L. Abbott superintendent, owns five claims in one group and another of eight claims on Coney and Divide creeks. Showings of ore have been developed in all of them by tunnels. On Botha creek it has three claims and on the slopes of Sunnyside creek six claims and four fractions. On Marble creek it owns eleven quartz and five placer claims. They have twenty-seven men at work on eight-hour shifts, wages being $2.50 per day and board. The principal works and buildings are on the Sunnyside claim, 3½ miles east from Roosevelt. An upper working tunnel is driven in a westerly direction for 425 feet; an auxiliary tunnel 50 feet higher up the hill is in 200 feet, connection being made between the tunnels by a winze. A north drift from the main tunnel is driven 200 feet and the face is in ore. The south drift is driven to the south line of the claim. Raises of 25 to 35 feet and other drifts from the main tunnels have developed a body of milling ore averaging $7 gold per ton. Treatment will be by amalgamation and cyanide. The company has machinery for a 40-stamp mill at the end of the wagon road and at Nampa a 12-drill compressor and a 100 H. P. boiler, which will be taken in in the spring. The mill will be put up on Marble creek and the ore sent down from the tunnels to the mill by an aerial tram 1½ mile long. A power plant for generating electricity will be built 8 miles down Marble creek, below the mouth of Cottonwood creek, where it is estimated a sufficient head of water can be had to develop 5000 H. P. Below the company's buildings on Sunnyside creek a lower tunnel is being driven by two shifts to tap the ore at depth of 480 feet below the apex of the bill on the Sunnyside claim in horizontal distance of 1200 feet. A 15 H. P. boiler runs a blower furnishing air in the tunnel, and a sawmill for cutting lumber for general purposes. The tunnel is in 864 feet. It is expected the wagon road, as surveyed to Roosevelt, will be completed in June.

At the Black Horse and Shiner claims, between the Sunnyside and the Dewey mines, owned by T. Neighbors of The Dalles, Or., a shaft is being sunk and is down 50 feet. It has passed through conglomerate and is in clay and talc.——The East Dewey Co. owns a group of claims north and east of the Sunnyside ground, and work is under way on three tunnels. T. Matthews is superintendent.
Roosevelt, Jan. 9.

R. S. Law and J. McMahon are reported to have bought a group of quicksilver mines in Thunder Mountain district, near Roosevelt. The ore is said to average 6% mercury. Development will start this month.

The Kamiah M. Co. has been incorporated by E. L. Marvin, J. J. Turrish, M. A. Kinne, R. L. Edmiston, W. T. Birdsall, P. Gerhart and H. K. Cross, and has bought sixteen claims in Buffalo gulch, 3¾ miles northwest of Elk City. Development will begin in the spring. E. L. Marvin is president and headquarters of the company are in Spokane, Wash.

Manager W. Hegan of the Crooked River M. & M. Co. at Orogrande, southwest of Elk City, says he will make several changes in the mill this winter. The ore bins will also be remodeled.

Le Roy G. M. Co. has been incorporated under Washington laws, with main office in Philadelphia, Pa., to operate a group of nine full claims 1½ miles north of the Hogan mine, near Orogrande. On its ground Le Roy has timber supply, wood as well as water to run ten stamps. Its ore bodies are said to average 200 feet wide, carrying gold values. The company owns on the river water power for installation of an electric plant of 1500 H. P. F. Hyo of Spokane, Wash., superintendent, is building a mill and has development work under way.

Kootenai County.

With 120 men and 129 horses the Idaho-Continental M. Co. is shipping two cars of ore daily from the Continental mine, near Porthill, says W. T. Bailey, part owner. Snow covers the road from the mine at the top of the mountain, 6000 feet elevation, down to the Kootenai river, and sleighs are carrying the ore to the railway at Porthill. They expect to continue shipment at rate of fifty tons a day. The galena is said to carry 50% lead and 40 ounces silver. It goes to the Tacoma smelter and freight and treatment charges total $16 a ton. They are mining along the Continental lode for 3500 feet, the best ore coming from the new tunnel on the Jasper, the middle claim, where there is a shoot of shipping ore 3½ feet wide. The rest of the vein there for 25 feet is concentrating ore. Further north, in the Blue Joe tunnel, at 750 feet below the top of the hill, they are taking out ore at 600 feet from the portal of the tunnel. W. Roberts is superintendent.

P. Sherlock of Wallace, owning placer claims near the St. Joe basin at head of St. Joe river, says the past season he reached bedrock at 15 feet and completed a bedrock drain. He built a flume 1200 feet long of poles and logs. Heretofore it has been necessary to go 25 feet before bedrock was reached. The largest nugget found weighed $1.50, while many ran from 10 to 30 cents. The gravel is fine. These claims are 130 miles above the head of navigation of St. Joe river and 24 miles below its headwaters, near St. Joe basin, on Sherlock creek. To reach them it is necessary to go to Iron Mountain, Mont., 80 miles from Wallace; then up Cedar creek 20 miles and thence over the main range of the Bitter Roots to the St. Joe, says Sherlock.

Shoshone County.

The Gold Hunter mine, near Mullan, which was closed down several months ago, has resumed operations with J. Gearen of Wallace as superintendent, and twenty-five miners are at work. For the present the mill will remain idle, but it will be improved. The ore bodies will be blocked out. The company is of Minnesota men, with P. J. Hennesey of Chicago, Ill., one of the principal owners. D. P. Roblfing of Salt Lake City, Utah, is manager.

C. S. Crysler of Spokane, Wash., interested in gold dredging near Delta, says his Mascot dredger will resume in the spring as soon as the ice gets out of the creek. The tests of the ground for three and a half months last fall proved the dredger can handle 2000 yards a day with nine men. The Delta G. M. Co. has a dredger which can handle 1200 yards a day. It ran two months last fall. The Mascot dredger works to depth of 26 feet and for width of 20 feet, which is half the width of the gulch. Crysler says he has worked half way across the stream for 600 feet and has 3200 feet more to go.

MICHIGAN.

The output the year 1903 is reported at 190,000,000 pounds of copper by the Lake mines, an increase over 1902.

Houghton County.

No. 3, the northerly, or Mesnard, shaft of the Quincy mine, at Hancok, is 2000 feet in depth. The showing in the lower levels is said to be improving. At the surface the vein was narrow and lean in copper. Eventually this shaft will be connected with the workings of the North Quincy, under the Franklin mine. The output of the Quincy mine for month of December was 1202½ tons of copper.

Construction is progressing at the reduction works of the Michigan Smelting Co., 3 miles west of Houghton, and it is expected they will blow in the furnaces by July. This plant will handle the mineral of the Wolverine, Mohawk, Atlantic, Baltic, Trimountain, Champion, Winona and Michigan mines, says the Record.

The destruction of No. 1 shaft of the Isle Royale mine, near Houghton, by fire will probably curtail production for several months, until the shaft can be retimbered, though extra men can be worked on No. 2 shaft. It is expected to require six months to complete the repairs.

The Old Colony mine, near Calumet, reports having struck last week a nest of mass copper in crosscutting to the lode shown by the diamond drill.

The Elm River mine shaft, near Winona, is down 820 feet, and they are crosscutting the lode.

The Centennial mine "A" shaft, near Calumet, is down 2825 feet on the Kearsarge lode and drifting is in progress north and south at the 27th level. The shaft house is completed.

The product for month of December of the Copper Range Con. mines, near Painesdale, was as follows: Champion, 852 tons of copper; Baltic, 708 tons; Trimountain, 547 tons. The amygdaloid rock being taken from the Champion mine is said to be increasing in values. The air compressor which the company is putting in will increase the company's milling facilities 50%. The compressor parts filled sixteen freight cars when shipped. The machine has quadruple expansion cylinders and takes steam from special boilers at an initial pressure of 300 pounds per square inch.

The December product of the Atlantic mine, south of Houghton, amounted to 336 tons of copper.

Keweenaw County.

The Mohawk mine, near Allouez, month of December output amounted to 319 tons 700 pounds of copper. Two heads are operating in the mill and 1000 tons of rock are shipped to the mill daily. The third head is nearly finished and the equipment of shaft No. 4 is ready. Most of the additional rock will be taken from this shaft.

The Allouez shaft on the Kearsarge lode, near Allouez, was sunk 75 feet during December, giving it depth of 320 feet. Several months will be required to reach the lode and get levels run, says the News.

Ontonagon County.

The main shaft of the Victoria mine, at Victoria, is near the twenty-first level. Stoping ground has been opened up and production will begin. —— By cutting down its tonnage and increasing grade of rock treated, through selection, the Mass mine at Mass City is obtaining thirty pounds of refined copper per ton from rock stamped. The Mass mine yielded during December 160 tons of copper, consisting of eighty-five tons of mass and seventy-five tons of mineral, obtained from stamping 6400 tons of rock.

Superintendent Brady of the Michigan C. M. Co., at Rockland, says little drifting is being done at present, the ground already broken being more than sufficient for needs of the mill for some time to come. The production is equally divided between mass copper and that taken from stamp rock. The Branch vein is showing satisfactory values. About 250 tons of rock are being treated daily, which amount will be increased to the full capacity of one head, 500 tons.

MISSOURI.

Jasper County.

(Special Correspondence).—During the year 1903 the Joplin mining district produced 184,196 tons of zinc sulphide and 28,387 tons of lead sulphide (galena). This ore sold for over $7,000,000. The new year finds mining operations in the district in an active condition for this season of the year. The price of zinc sulphide concentrates for the week ending Jan. 9 was $38 per ton, which is the highest ever received for any corresponding week since this industry was established. The price for the same week in 1903 was $33.50; in 1902, $30, and in 1901, $27. In 1894 it was $18 per ton. Galena concentrates sold last week for $54 per ton, which is the highest price paid in any corresponding week, except 1900, for several years. The price in the same week for 1903 was $51, and in 1902, $42. The price of these ores generally rules low at this season of the year.

Joplin, Jan. 11.

In Sherwood, near Webb City, the Webb City Iron Works, on the Crellor & Young land, in a drift started south of the pump shaft on the 125-foot level, has opened up an ore body in spar ground. J. Stewart and G. Wright, owners of the Webb City Iron Works, say they will begin this week sinking the pump shaft to the 150-foot level, when they will extend the drifts into the ore body, and expect to have sufficient ore blocked out by spring to stope and supply a mill which they will build. Varnor, Rice & Co., on the same land, have been sinking their pump shaft to get water to clean their ore with, and are 130 feet deep. The company begins this week cleaning ore on hand jigs from the ore body that they sank into, which yields 25% zinc sulphide. On the Mitchell land, adjoining on the west, Nails, Martin & Co. and the Utility have resumed operations.

The 100-ton mill at the Hayseed mine, northwest of Carthage, was completed last week and is in operation.

W. Jones and F. J. Gay are sinking a shaft on Shoal creek, south of Galena, for the Galena G. M. Co. The company intends to prospect for gold. Several shafts have been put down. The deepest one, the Murdock shaft, is down 219 feet, but no ore has as yet been found there, says the News-Herald. Assays taken from some of the other shafts show values. The Murdock shaft will be sunk deeper.

W. G. Bryant and J. Durby of Carterville, at their new mine and mill at Neck City, report they have a face of ore 45x70 feet which they are opening up.

MONTANA.

Deer Lodge County.

A strike is reported made in the Olive May mine, in Olsen gulch, 7 miles west of Anaconda. The Olive May is owned by A. Dumouchel, A. P. Cloutier, J. P. Prouix and A. Bourbonnere of Anaconda. The samples taken show values in gold, silver and lead. The shaft has been sunk to depth of 250 feet, and the find was made in drifting. There are several other mines being worked in Olsen gulch, including the May Flower, owned by G. Gunn and C. W. French, and an iron mine owned by F. G. Brown. At the May Flower a tunnel has been run and two ore chutes crosscut at depth of 300 feet. The average value is $15 a ton.

Granite County.

The Milwaukee G. Extraction Co., which owns twenty-five claims near Phillipsburg, is building a 100-stamp cyanide mill. Development work has been in progress for three years and a vein of ore 60 feet wide, running $4 per ton, is said to have been opened.

Kaiser Bros. and C. Williams, who own mining claims on northern slope of Red Hill, north of the Hope Co.'s ground, last week resumed work by putting men to work on their tunnel. They have a body of iron ore carrying 4% copper and silver values. It is in Flint Creek district, 2 miles north of Philipsburg.

Jefferson County.

The West Montana M. Co. has been organized by S. L. Burbridge and J. Winscot of Helena and has taken over a group of mines near Basin. There are six claims in the group on which considerable development work has been done, showing a vein of 40 feet at the crosscut. Values are in gold, silver, copper and lead. The claims are 2½ miles from the Great Northern and Northern Pacific railroads, and there is said to be sufficient water for a concentration plant on the property. Work will be started this month.

L. E. Dubois of the Red Berg M. Co., manager of the Reliance mine in High Ore gulch, near Basin, says this property has been prospected by a tunnel, and the company is preparing to increase development work.

Lewis and Clarke County.

The South Bend M. Co. is increasing development work on its group adjoining the Peerless Jennie, in Ontario district, near Helena. A 500-foot tunnel is being run which is in 260 feet and which will give depth of 2250 feet below the upper tunnel, says the Record. In the upper tunnel a vein has been struck which runs fifty ounces silver and $10 gold per ton. The company has leased its Uncle Tom claim to Eastern men, who will develop it.

Park County.

The plant of the Kimberly-Montana M. Co. at Jardine, including that at the Bear Gulch group, will be operated by electricity.

Silver Bow County.

The average daily output of ore of the mines of Butte is 10,000 tons, of which one-half goes to the Washoe smelter, at Anaconda, and the remainder to the Colorado smelter, the Montana Ore Co. smelter, the Butte & Boston reduction works and to the Boston & Montana smelter at Great Falls.

The Amalgamated C. Co. is working its mines and smelters full blast and expects to continue. It is employing nearly 12,000 men, distributed as follows:

In Butte mines	6,000
Butte smelters	600
Anaconda smelter	1,800
Great Falls smelter	1,300
Coal mines in Montana	500
Coal mines in Wyoming	650
Lumber camps, etc	800
Prospecting, etc	300
Total	11,950

The company ships to its smelters 9700 tons of ore per day. Exclusive of the salaries paid to local officials, the Amalgamated pays out in Butte in wages alone $22,500 per day.

NEVADA.

Churchill County.

It is reported the Hollinger Bros. group at Pike's Diggings in Eagle valley, near Eagleville, has been bonded by D. Francis and G. P. Smith for $10,000. A shaft has been sunk to depth of 125 feet, and free milling ore is exposed. The ledge shows width of 12 feet. The camp is said to have timber and water close at hand.

Esmeralda County.

T. L. Oddie of Tonopah bought an interest in three groups of claims known as the Diamond Joe, Joshua Man and Mattie groups, 3 miles east of Goldfield, southeast of Tonopah.

Eureka County.

At the Ruby Hill T. & M. Co. mine the south crosscut in the tunnel of 20 feet last week broke into ore. More men have been put on to increase development. The find made is in 1700 feet and at depth of 700 feet from the surface.

Humboldt County.

Assays on ore from the strike in the mine of the Glasgow & Western Exp. Co., near Golconda, show 10% copper, 6.5 ounces silver, with $4 gold per ton, says J. Farren, general superintendent. The find is on Peacock ground in the Adelaide group of mines, and 3000 feet distant from any ground previously worked.

Lander County.

C. S. Vadner, manager of the Gracie group of copper claims at Elder creek, near Battle Mountain, has made arrangements for further development of the Gracie.

Lincoln County.

The Good Hope mine at Searchlight has resumed operations, says Superintendent Drummond.——The shaft on the Searchlight M. & M. Co.'s mine is down 200 feet.

Lyon County.

H. E. Miller, part owner of the Bluestone and Douglas group of copper mines near Yerington, says the Bluestone, after being under bond for some time, has reverted to Miller & Co. Superintendent A. F. Whitman has men doing development work on the mine.

Nye County.

The California-Tonopah M. Co. has closed its mine, which adjoins the Gold Hill at southeast part of Tonopah.——At the Halifax mine the water has been pumped out of the 600-foot level and a station cut at which the pump is placed. The remaining 40 feet of water in the shaft is being pumped out and three shifts will be put to work sinking. It is intended to sink to the 1000-foot mark before crosscutting.

Washoe County.

W. J. Alexander and J. W. Simpson report opening up gold-bearing rock on their claims, 29 miles north of Reno and northwest of Wadsworth. The vein is 18 inches wide, of free-milling ore, and was cut at 50 feet by a tunnel.

NEW MEXICO.

Taos County.

A. E. Eckles of Alamosa, Colo., is developing the Brown Palace mine on Malette creek, near Red River. The ore assays $10 gold. Eckles will build an arrastra.

OREGON.

Baker County.

Superintendent W. Rummery has put men to work on the Gipsy Queen mine, near Sumpter. A shaft is being sunk at the mouth of the tunnel, which runs on the vein.

B. MacDonald of Spokane, Wash., manager of the Cornucopia group of mines, says work is progressing. The group comprises forty-one mining claims, twenty of which are patented. The property is equipped with mining and milling machinery which is driven by electricity generated at a power station 2½ miles from the mines. The electric plant has capacity of 1000 H. P. The position occupied by the mines makes it possible in their development to get considerable depth by cross-cut tunnels. Two crosscut tunnels are to be driven; the shorter will be 4000 feet in length, and its course will cut two of the principal veins of the district at average depths of 1000 to 1500 feet below the surface. The lower tunnel will be driven at a point near the foot of the mountain and 1000 feet vertically under the shorter tunnel. Near the portal of deeper tunnel a mill will be built, and all the ore mined will pass by gravity through raises connecting the workings with the tunnel through which it will pass to the mill.

Columbia County.

F. Payne & Co., of Scappoose, have bought the smelter plant at Linnton, and removed it to their mine on north fork of the Scappoose river, where they expect to produce pig iron. The iron ore deposits at this place have been proved by tests to carry 60% iron, says the Telegram.

Grant County.

Mills will be built on both the Belcher and Red Lion mines, near Granite, in the spring, says Superintendent P. A. Brady. A 20-stamp mill will go in on the Belcher and a smaller plant on the Red Lion. Development work is progressing. At the Belcher the lower tunnel is being driven and a raise made on No. 3 ore shoot from lower to upper tunnels. The distance is 153 feet. In the tunnel No. 4 shoot has been cut.

Josephine County.

The Golden Drift M. Co., operating on Rogue river, 3 miles above Grant's Pass, has completed the main structures of its power dam across the Rogue, and has suspended work for the winter. The cribs have been all filled in with stone and barred over to resist the winter freshets. In the spring the turbines and pumps will be placed. At the start 5000 H. P. will be generated. During this winter the company is operating its dry diggings placers, water being derived from the hydraulic ditches tapping Jones creek. This stream is small, and through the aid of a reservoir water for six hours' run each day is secured for the giants.

Burton & White have bought seven placer claims on Reuben creek near Mount Reuben, near Grant's Pass. They will put in machinery—a boiler, engines, derricks and cables and hydraulic giants.——The Oregon M. Co., composed of Seattle, Wash., men, is doing development work on Wagner creek. The company is putting in a 5-stamp mill. It owns fifty acres of mineral land on Wagner creek, with water rights. The claims are the Pittsburg, Little Pittsburg, Riverside, Rutb, Double Jack and Pilgrim. The mill is expected to be in operation this week.——Imbler & Isaac are developing and have equipped an hydraulic placer mine on Chetco river, south of Kerby. Water is derived from Chetco river. The diggings are said to carry coarse gold and platinum and are not deep, running but 6 and 8 feet.

J. B. Crawford, with Eastern men, operating mines near Grant's Pass, says he will build a smelter at Grant's Pass which will handle custom ores in addition to their own.

Lincoln County.

B. F. Jones, operating placer mines on the ocean beach at Otter Rock, north of Newport, has taken 1½ miles of beach. The sand is said to carry platinum and flour gold. It is intended to test the beach and secure if possible a process to save platinum.

Multnomah County.

Work still continues steadily on the oil well near St. Johns by the Ogden Petroleum Oil Co. The well is down 495 feet, and the refuse from the drilling is impregnated with oil. At the depth attained the cuttings show shale, coal and lignite mixed with slate and carrying petroleum, says the Telegram. It is intended to go to the depth of 1000 feet.

Wallowa County.

D. C. Guernsey, superintendent and manager of the Eureka M. Co., near Enterprise, says their sawmill at Buckborn Springs is getting out timber. The company is completing the smelter, having the foundations done and the frame work going up. Other work under way is the building of a suspension bridge across the Imnaha river to connect the mine and smelter; also a dam across the Imnaha to operate and light the mine and smelter. Another steamer is being built for transportation on the river and is expected to be ready May 1.

SOUTH DAKOTA.

Lawrence County.

With the operation of 100 additional stamps at the Amicus mill at Lead, making 240 at this plant, the aggregate number of stamps dropping in the Homestake system will be 1000. The framework of the Amicus is completed and inclosed. A portion of the machinery is in position.—— At cyanide plant No. 1 at Lead arrangements have been made for building an L-shaped structure 200 feet in length by 150 feet in width at the west end, containing floor capacity for six additional tanks, making a total of twenty sand vats for the entire plant. The addition to the cyanide plant is expected to be ready by the time the additional stamps to the Amicus mill begins dropping.

It is reported the Golden Reward smelter, below Deadwood, will resume operations, treating ore from the company's mines in Bald Mountain district. H. Franklin is manager of the Golden Reward. The smelter was shut down eighteen months ago on account of a strike.

The plant for the reduction of tin ore for the Tinton M. Co. at Tinton is nearing completion and is expected to be ready for operation in February. The building is enclosed and the machinery is being placed. The boilers have been set. A compressor is on the ground. The mine is opened with a tunnel into one of the ledges, and is blocked out for stoping.

Pennington County.

The Keystone Recorder says machinery for the Lucky Boy mine, near Keystone, arrived last week, having been delayed in transit. Development work will be resumed.

TENNESSEE.

Polk County.

The Tennessee C. Co. at Ducktown expects to produce between 14,000,000 and 15,000,000 pounds of copper during 1904. The company is planning to increase its furnace capacity to six furnaces by 1905, which is twice the number now in operation, including the one blown in Dec. 17.

UTAH.

The situation in the coal camps in eastern Utah is showing improvement, says the News, and it is expected the normal output of coal will again be available by Feb. 1st. As a result the metal mining districts no longer fear danger of a coal famine for the mines, mills and smelters.

Beaver County.

Work has been resumed on the Curzon group in Star district, near Milford, under J. Forgie. This group adjoins the Copper King.——The Catawba M. Co., owning eleven claims in Beaver Lake district, proposes to increase work during the coming year, says President and Manager Botkin.

Superintendent Trenam reports an increased flow of water at the Beaver Con. mine, near Milford, amounting to fifteen gallons per minute. They have been able to hoist it thus far, but a pump will be put in.——Manager B. Lloyd of Salt Lake City of the Copper Ranch and Copper Mountain companies, says at the Copper Ranch it is intended to resume sinking on the Jewel mound incline, which is 125 feet deep. At the east end drifting will be done from the bottom of the shaft.——W. J. Bowring, who has a lease and bond on the Copper Mountain mine, has arrived from Salt Lake City to put on more men to increase development.——Neihurg & Erickson have resumed work on the Humboldt mine, near the Kitty Cluff mine.

Box Elder County.

On the west side of the Great Salt Lake, west of Ogden and 10 miles from Lucin, on the Southern Pacific Railway, the Giant Copper Queen M. Co., C. A. Dugger manager, is opening up ore. The mine is being worked by a tunnel, which has been driven 1020 feet, at which point a ledge was cut showing a width of 13 feet. The group is 3 miles from the Copper Mountain mine.

Iron County.

At the Johnny mine at Stateline the sinking of the shaft to the 300-foot level has been completed and drifting will start towards the ore body shown in the upper workings. The mill is closed down pending addition of slimes attachment to the cyanide department. The plant will be in operation again by Feb. 1st.

Juab County.

The Yankee Con. of Tintic, near Eureka, shipped during 1903 a total of 7600 dry tons of ore, from which, says Secretary Amsden, there was smelted 3,865,827 pounds of lead, 157,619 ounces of silver, and gold of value of $16,000. While the management has first-class ore exposed, it is confining the output at this time to the second-class while continuing exploratory work.

At the mines of the Morning Glory G. M. Co., up Undine hollow near Robinson, men are drifting on the vein, which is 5 feet wide. A shoot a foot wide has been opened up.——The South Swansea mine, near Eureka, owing to the smelters not desiring to handle that class of ore, has been closed indefinitely.

Morgan County.

The Park City Co-operative M. Co. of Park City has bought the Copper Mountain group of ten claims 5 miles from Morgan, on which it will start development work this week.

Piute County.

Development work is under way on the Marion group of mines near Marysvale, adjoining the Log Cabin mine, says B. D. Luce, manager. They have decided to tap its ledges by tunnel. From its outcrop, the main fissure shows $3 gold per ton. The main tunnel on the Log Cabin group is in 480 feet, the last 80 feet having been on the strike of the ledge, showing an average of $3.56 gold per ton. In addition to this, the company is driving two other tunnels.—— The Bradburn group, in same location, is being developed by a Pittsburg Pa., company.

Work is reported progressing at the Hope group of claims near Marysvale. Two shafts will be sunk. Men have been put to work at the paint mines near Koosharem, which are owned by Kansas City, Mo., men. J. M. Jones is superintendent.

Salt Lake County.

The production of the Utah Con. mine and smelter for mouth of December was the largest in the history of the company, says the News, and 18,000 tons of ore were sent from mine to smelter. This produced 1,250,000 pounds of copper bullion. The monthly product for 1904 is expected to reach 1,500,000 pounds of copper.

At the Ohio C. (Columbia) Co. mine at Bingham the station at the 115-foot level was completed last week and drifting east and west begun. Sinking was also resumed, and the shaft will be put down to 215 feet. Breaking ore in the All's Well stopes has resumed. An extension of the Copper Belt railroad from its former lower terminus to the Winnamuck mill bin is being made and on its completion the Columbia ore will begin to move.

A deep tunnel to open up the Copper Glance group, near Bingham, has been started in McGuire gulch by J. E. Edmunds, manager. The tunnel will cut the main ledge at 1800 and 750 feet vertically under the old workings in the Keystone gulch, which were abandoned owing to water.

Bingham ore shipments via the Copper Belt Railroad comprise 300 tons daily from the Commercial mine for the Bingham Con. smelter, 150 tons daily from the Boston Con., and 200 tons daily from the Yampa.——Connection between the Columbia and its mill is completed and ore will be started this week.——During December the Bingham Con. Co. at Bingham shipped 1000 tons of ore from the Fortune mine. Shipments from the Dalton & Lark, Brooklyn and Fortune continue to average 150 tons daily, and from the Commercial 300 tons. As the Dalton & Lark is now drained by the Mascot tunnel, and the Brooklyn nearly so, driving of the tunnel may not be resumed until spring, says the Bulletin. It continues to discharge a large volume of water, with beneficial results to several neighboring properties.

The Rob Roy M. Co., organized to develop the Rob Roy group on Clipper hill, near the Zelnora, Argentine and Morning Star mines, near Bingham, has begun work. The officers are E. Rauch, A. McKellar Jr. and E. McGurrin.

Plans are under consideration for conveying ores from Alta camp to the lower end of Little Cottonwood canyon by aerial tramway and thence to the smelters over the tracks of the Rio Grande Western Railway, says President T. Jacobson of the Columbus Con. M. Co., the tram to run from the mine to the company's power plant, 3 miles above Wasatch. It is thought the present cost of transporting ores to the smelters can be reduced 50%. Usually the fall of snow in the camp in the winter is heavy, says the News, and occasionally the roads become blocked. With a tramway in operation, no interference of this kind would occur. There has been some talk of rebuilding the old rail tramway line and equipping it with electric motors and cars.

Sevier County.

The B. W. & H. mine in Henry district, near Richfield, has temporarily closed down with the completion of the tunnel contract. A length of 720 feet has been reached. A consolidation with the Blue Eagle, an adjoining group, is proposed, and no more development will be done until this is settled.

Work continues in progress at the Signal Peak mine on the Fish creek side of Gold mountain, near Richfield, says Manager J. H. Nelson. The tunnel is nearing the vein.—— A mill, next spring, is proposed, says W. G. Elvin, manager of the Trapper's Pride mine, on the Fish creek slope of Gold mountain. Superintendent A. D. McLain has cleaned out and retimbered the workings. The main tunnel has been increased 500 feet in length since summer. It follows a 15-foot vein that

runs $9 gold per ton at a vertical depth of 400 feet.

Summit County.

The Cougar G. & S. M. Co. has been incorporated at Park City to operate the Cougar group of five lode claims on the Smith & Morehouse fork of Weber river. The officers are: R. McDonald, B. J. and A. M. Martin.

Tooele County.

The Honerine M. Co. at Stockton, W. F. Snyder manager, reports the drain tunnel completed to length of 5850 feet and progress is being made at rate of 7 feet a day. The mill will be ready for operation by Feb. 1st. While the drain tunnel is not expected to reach the ore bodies of the Honerino till next summer, the mill during the first six months of its operation will be supplied with ores from the surface workings and from other mines of the camp.

The Reynolds group at Stockton, which adjoins the Honerine on the west, has been taken over by F. G. Richmond, B. F. Bauer and S. V. Ham of Salt Lake City for $100,000. The group is of eight full claims and two fractions, and was mined in former years. The driving of the Honerino tunnel will unwater the ground in the Reynolds group. It is intended to start work on the group this month. A plant of machinery will be put in. F. G. Richmond is manager.

The Geyser-Marion mill at Mercur is in operation, under direction of the Green Reduction Co. of New York, which is working over the tailings dumps.

The annual report of the Black Diamond M. Co. of Stockton, says Manager Dedorichs, shows work has been resumed, with a crosscut being extended from the 180-foot level to the Ada vein. The most important development is that made in Black Diamond ground through the Honerine tunnel. The Black Diamond adjoins the Honerine.

WASHINGTON.

Ferry County.

The Nob Hill mine at Republic is progressing under lessees. Thirteen men are working underground and drilling is by hand. The raise from the tunnel is up 35 feet and will go 60 feet more to connect with the surface stope. Ore is being stoped from the tunnel level upward and is being shipped. The stope is 7 feet wide. More men will be put on.

Okanogan County.

L. Hedges of Wauconda says the Wauconda tunnel is in 1300 feet and he has seven men on two shifts driving it ahead. He is also operating mines at Buffalo Hump, Idaho. The litigation between the company and J. B. Rossman has been settled, the company buying the Rossman mill and all of the interests owned by Rossman & Brown in the Wauconda group.

Pierce County.

Work is progressing on the improvements under way at the Tacoma smelter at Tacoma. These consist of additions to the lead refining plant and a three-story brick bag house and a steel blast furnace. The bag house, which is 110x60 feet, is expected to result in additional saving to the smelter. The apparatus includes 1000 bags, being each 25 feet in length by 2 feet in diameter, which are placed suspended with the open end downward. The smoke is passed into the bag house and forced through the bags, which catch all the valuable mineral otherwise carried off in the smoke. It is expected that the bag house will be in operation by March 1. The new steel blast is completed and will be fired up this week. It will make the fourth lead furnace in operation at the plant. Its capacity will be 200 tons daily, and it will nearly double the capacity of the lead plant. The total capacity of the smelter will be 300 tons of copper ore and 500 tons of lead ore daily.

Stevens County.

L. P. Larson of Spokane reports buying the Last Chance (the Silver Butte), on Deep creek, near Northport, and first payment of $3000 made. The ledge has been opened up at depth of 300 feet, showing 4 feet of galena. Adjoining the Last Chance group is the Great Western.

D. F. Stroheck, superintendent of the Copper King mine at Chewelah, reports surface improvements completed and underground work resumed. Sinking will be continued in the new shafts, as well as drifting and stoping on the ore shoots. They expect to begin shipping in February. He says the ore averages $30 per ton, and they will get a rate of $4.50 for freight and treatment. Superintendent Parker has men at work on the June-Echo.——The development of the Nellie S. mine, under Manager Baker, is progressing.——The Jay Gould is preparing to resume work and ship ore.

WYOMING.

Carbon County.

J. F. Ledhetter of Salt Lake City, Utah, operating the Beulah mine, at Battle, says he is getting out copper ore and the tunnel is nearing the contact. The main tunnel has been driven 825 feet, and besides this, 250 feet of drifting has been done.

FOREIGN.

AFRICA.

Transvaal.

The production of gold for the Transvaal for month of December is reported at 285,000 ounces, compared with 279,813 ounces in November, 1903, and 196,023 ounces in December, 1902. The following are the figures in fine ouncos:

Month.	1903.	1002.
January	199,279	70,341
February	196,513	81,405
March	217,465	104,127
April	227,871	119,589
May	234,125	138,602
June	238,320	142,780
July	251,043	149,179
August	271,918	162,750
September	276,197	170,802
October	284,544	181,440
November	270,813	187,375
December	285,000	106,023
Totals	2,962,088	1,705,413

AUSTRALIA.

New South Wales.

At Jembaicumbene there are four dredgers at work and another is being built.——Opal is reported struck at depth of 73 feet at White Cliffs by Dunlop & Vincent, this being the deepest point that the gem has hitherto been met with on the field, says the Government Journal.

Drilling operations that have been in progress at Cessnock, near Maitland, for some months past have shown a seam of coal. The measure was reached at depth of 260 feet and has been proved for thickness of 27 feet. The drilling operations are being carried out on the H. Smith mine, in conjunction with the Caledonian Co.

BRITISH COLUMBIA.

Boundary District.

At the Athelstan mine, near Greenwood, the number of men at work has been increased to thirty and ore shipments are also being increased.

East Kootenay District.

At the North Star mine, near Fort Steele, thirty men are at work and development is progressing. Shipments will be resumed before Feb. 1st. It is reported that an ore body 3 feet wide has been opened in the 300-foot level. The shaft will be sunk to a depth of 500 feet.

The total output of the three Crow's Nest collieries operated by the Crow's Nest Pass Coal & Coke Co. for the year 1903 is reported as follows:

Coal—	Tons.
Coal Creek (Fernie)	240,000
Michel	262,000
Morrissey	150,000
Total	652,000
Coke—	**Tons.**
Fernie plant	96,000
Michel plant	70,000
Total	166,000

The present daily capacity of the three collieries is as follows:

	Tons
Coal Creek	1,200
Michel	1,400
Morrissey	800
Total	3,400

The capacity of the three coke oven plants, two of them still incomplete, is estimated at between 1200 and 1400 tons of coke per day.

The following table shows the number of men on the company's payroll at present:

	Miners.	Oven-men.
Coal Creek	427	117
Michel	583	105
Morrissey	291	25
Totals	1,301	247
Men on general construction		250
Management, engineering, clerical		37
Total on payroll		1,835

The management of the St. Eugene mine at Cranbrook is putting in a slime concentrating process to increase the savings from the lead concentrating ores. It is estimated that 1½% of the values are lost in the tailings, says the Review. The process will be to rework the tailings and slimes heretofore dumped into the lake. A building 150 feet long by 25 feet wide has been built on the dump at the lake shore. On the upper floor will be settling tanks and on the lower floor a series of concentrating slimes tables.

Nelson District.

The Dundee mine at Ymir has been sold to A. E. Rand et al. of New Westminster and first payment of $5000 made.

Slocan District.

A. K. Stewart has resumed operations on the Whitewater Deep mine, near Sandon. He has seven men at work and has started driving a crosscut.——It is stated the Slocan Star is overhauling the concentrator and will put in a magnetic zinc separator in addition to other machinery. Operations will start in February.

Rossland District.

The Rossland Miner gives the following output for 1903 for the mines of Rossland district:

Mine—	Gross Tonnage.	Estimated Gross Values.
Le Roi	182,000	$2,112,000
Centre Star	81,957	1,093,353
War Eagle	59,948	813,198
Le Roi Two	22,000	352,000
Le Roi Two (milled)	2,000	16,000
Jumbo	4,205	52,740
Spitzee	570	8,550
I. X. L. (milled)	2,000	12,000
Kootenay	7,606	87,469
Giant	830	10,375
Velvet	3,376	67,520
Iron Horse	40	320
White Bear	297	4,145
O. K.	25	625
Homestake	90	675
Total	377,131	$4,631,270

The output for the past ten years has been:

Year—	Tonnage.	Estimated Value.
1894	1,856	$75,000
1895	19,693	702,359
1896	98,075	1,243,360
1897	68,804	2,007,780
1898	111,282	2,470,811
1899	180,300	3,211,400
1900	221,902	3,500,000
1901	279,133	3,500,000
1902	329,580	4,274,352
1903	377,134	4,631,280
	1,705,668	$25,816,340

In the payrolls of Rossland mines the amounts disbursed by the mines are divided under two headings—one for wages of mine workers and the second embracing salaries paid to managers and office staffs. Following are the amounts:

Mine.	Wage Roll for Year.
Le Roi	$385,000
Centre Star	162,500
War Eagle	136,700
Le Roi Two	102,000
Kootenay	45,000
Jumbo	25,000
Spitzee	12,000
Giant	4,000
Velvet	25,000
White Bear	50,000
I. X. L.	3,000
Other Mines	25,000
Total	$975,200
Mine salaries (estimated)	$45,000
Total	$1,020.000

This does not include the payroll of the Northport and Trail smelters nor the amount expended in prospecting.

The returns for the year 1903 from the Rossland mining recorder's office show:

Certificates of improvement	14
Certificates of work	136
Payment in lieu of work ($100)	2
Claims recorded	64
Bills of sale, etc., recorded	24
Water grants issued	6
FREE MINERS' CERTIFICATES.	
Companies	15
Personal	466
Substitute personal	1
Special personal	11
	493
Existing crown granted mineral claims, (approximate)	657

A feature of the foregoing is the number of crown granted mineral claims existing within the boundaries of the Trail Creek or Rossland mining division. The division is one of the smallest in area in the province. The expenditure in work on these claims, together with costs of procuring the crown grant in each instance, will average $1000. The acreage under crown grant is over 20,000.

West Kootenay District.

A strike is reported from the Oyster-Criterion mine, Rossland, near Camborne. Additional men are being put on and the stamps are dropping steadily at the mill. Manager M. W. Pool says thirty tons of ore per day are being treated. The rock being put through is from the Rossland, and development is being increased on the Oyster and Criterion with machine drills. They propose to add ten stamps to the 10-stamp mill.

W. F. Teetzel has bought the Golden West and Crown King claims for $25,000. These claims are in the Poplar Creek district, in the Lardeau.

INDIA.

The annual report of the Champion Reef G. M. Co. of India, Ltd., operating in Kolar section of Mysore district, has been issued, showing 174,115 ounces of bar gold obtained from 173,629 tons of quartz crushed in the mills, an average yield of 19 dwts. 21 grs. per ton; while 32,335 ounces were gained by the cyanide process from 246,300 tons of tailings, an average yield of 2 dwts. 15 grs. per ton. These figures, compared with those for 1902, show an increase, the tonnage milled being an increase of 39,541 tons. Better duty has been obtained from the batteries, an average of over 14,000 tons per month having been crushed: and with regard to the tailings, the additions to the cyanide plant built in 1902 have been in full operation, so that the total quantity treated has been maintained at an average of 20,000 tons per month. The yield per ton of bar gold from the quartz and tailings together equalled 1 oz. 2 dwts. 12 grs., or 6 grs. per ton less than in 1902. The total returns for the year amounted to 206,450 ounces of bar gold of the value of £782,756. After deducting royalty payable under the leases, and adding other receipts in the income and expenditure account, an income of £749,419 results. The total costs charged against this income amounted to £308,078. The mining and milling costs were 2s. 9d. per ton less than during 1902, and 7s. 6d. less than in 1901. The tailings costs are down 1s. 1d. per ton. The comparatively large reduction in the tailings costs is largely due to no longer having to pay royalty to the Cassell Co. on the gold produced by cyanide process. During the year additional mining rights were bought from the Gold Fields of Mysore Co. Preparations for starting the new vertical shaft, projected to strike the lode at depth of from 3500 to 4000 feet, have been made and sinking begun. The Cauvery electrical power scheme having proved a success, the company, under agreement with the Mysore Government, is preparing to increase this supply, which is expected to be available by July. The extra horse power thus obtained will be used for driving the air compressor, which at present is working under steam. The central electric power station will be finished and the substitution of electricity for steam as motivo power for all the machinery on the mine completed. No difficulty has this year been experienced in regard to a sufficiency of water, the weather in the district of the mines having been favorable for keeping the tanks fully supplied. During the past three months the rainfall has been abnormal, causing considerable damage in the locality. Mining development work for the year exceeded that of 1902 by 2376 feet, the total amounting to 3¾ miles.

MEXICO.

Chihuahua.

The Encinillas Mines, Ltd., has its smelter at Santa Rosalia, in operation, and has on hand five road traction engines capable of hauling seventy-five tons of ore each at a trip in the two cars built for the purpose. It is expected the engines will make a trip with a load from the mines to Santa Rosalia, a distance of 60 miles, in a day. The road to the mines has been shortened, and it is stated that 10% grade is the heaviest on the route. At the mines electric power is used for hoisting and for lights for the buildings and mines. The deepest shaft is 430 feet.

The Pinos Altos mines, at Pinos Altos, have been sold to W. P. Dunham and associates of Denver, Colo., and Los Angeles, Cal. The mines produce silver-gold ores, and are equipped with a 55-stamp mill.

Coahuila.

La Constancia M. Co. of Saltillo is operating the Deonea, Guadalupe, 3a. Zona, Providencia, La Blanca and Esmeralda claims in Monclova district, 125 kilometers east from Escalon, Chihuahua. The mines are being developed through fourteen shafts, two tunnels, driven an aggregate of 1500 feet, and drifts, crosscuts, levels, etc. The ore is said to carry silver, lead and copper, averaging $30 per ton. They have five double steam hoists, five pumps with capacity of 1094 gallons of water per minute, ten boilers aggregating 400 H. P., and three horse whims.

A deal is said to be under way hy St. Louis, Mo., men to huy the La Luz mine, owned by V. Garza & Bros., in Muzquiz district. The mine is said to carry lead and silver values.

Durango.

The Penoles M. Co. of Mapimi has put up an electric power plant to do away with steam hoists, and concentrate the power supplies of the company. The cost was $400,000. The new machinery consists of four boilers, aggregating 2500 H. P., two engines, and two three-phase alternating current generators. The new plant is in operation.

An American company is reported developing the sulphur mines at Cardenas y Lugo, near Conejos, on the Mexican Central, under an option. E. F. White is manager.

Sonora.

It is reported the Zeckendorf group (the Old Goldtree group) will be reopened. L. Zeckendorf & Co. own twenty-three claims in the group. A tunnel will be driven cutting all the ledges at a depth of over 1000 feet.

The Constitution & Italia G. M. & M. Association, operating in Hermosillo district, 25 miles east from Hermosillo, reports work progressing. The mines are on a gulch running northerly 2 miles southwest of Tortuga mountain. The workings in the Italia consist of one tunnel, five shafts and several drifts, all in ore and aggregating 600 feet. The following table of cost for mining and milling sixty tons of ore (a day's run of the

milling plant) is given by the superintendent:

MINING.	Mexican Money.	
10 Miners at $1.75	$17.50	
1 Foreman	2.50	
Powder, fuse and caps	7.50	
Wear of tools	2.50	$30.00
DELIVERY OF ORE TO MILL.		
4 Men (shovelers) at	$1.50	
1 Car handler	1.50	
1 Hoistman	2.00	9.50
MILLING.		
2 Millmen at	$3.00	$ 6.00
2 Helpers at	2.00	4.00
2 Firemen at	1.75	3.50
1 Pumpman		2.00
1 Rockbreaker man		1.75
1 Blacksmith		4.00
1 Blacksmith helper		1.50
1 Foreman (superintendent)		10.00
1 Bookkeeper and assayer		5.00
2 Woodwheelers and corders at	1.50	3.00
2 Cords of wood at	5.00	10.00
Oil and lights		5.00
Quicksilver—loss of		1.50
Repairs, etc		3.75 $61.00
Total		$100.50

This is equivalent to $40 to $50 gold, according to fluctuation of Mexican silver, or 66⅔ cents to 80 cents United States money. The plant includes two 5-foot Huntington mills (each with a daily capacity of thirty tons of ore), a 70 H. P. engine, a 50 H. P. boiler, a 6-inch discharge pump. It is intended to add two more Huntington mills. For present use there is an ample supply of water coming from shaft No. 4. For the larger mill they will put in a pumping plant and pipe line from the Arroyo de la Junta, 600 yards distant, and at a vertical depth of 100 feet, in which all the year flows sufficient water. Wood is at hand, and the company owns interests in the Rancho San Francisco, which gives it the right to cut wood.

Zacatecas.

The Asturiana y Anexas group of 214 pertenencias, 5 kilometers southeast from Zacatecas in Mexico district, are owned and operated by the Asturiana y Anexas M. Co. of Zacatecas. The ground is developed by twenty shafts, one tunnel driven 900 feet, and crosscuts, drifts, etc. The maximum depth of several of the shafts is 700 feet. Equipment consists of seven Chilean mills, ten hand windlasses, two engines and two boilers. After going through the Chilean mills the pulp is treated by the patio process. The ore is said to carry silver, with a little gold.

It is reported the Mazapil C. Co. will build a smelter at Saltillo, Coahuila, to handle its ores from the Mazapil Concepcion del Oro mines. The company has been shipping to other smelters and it owns eighty-three producing properties at Mazapil.

SIBERIA.

W. McCornick of Salt Lake City, Utah, of the Siberian Exploration Co. operating in Eastern Siberia, says equipment has been put in with which they can handle 2500 tons of gravel daily. The gravel averages 25 cents per cubic yard. This capacity will be increased in 1904. Sluicing will begin again in April. The option obtained by McCornick on gold-bearing lodes in Siberia was relinquished by him after some exploratory work the results not being satisfactory.

TASMANIA.

High-grade ore is reported struck in the north stope, No. 2 level, of the Mount Rex tin mine at Mount Rex.——A diamond drill hole put down on the site of the balance shaft at the Lyell Blocks mine, near Mount Lyell, has proved the existence of a body of copper bearing clays, which is said to have averaged up to 3% copper.

Personal.

E. B. BURNS of Gold Beach, Or., is in San Francisco, Cal.

A. CARMICHAEL of Atlin, B. C., is in San Francisco, Cal.

E. B. WICKS of Salt Lake City, Utah, is in San Francisco, Cal.

A. SUTHERLAND is assayer at the Ajax mine, near Eureka, Utah.

T. R. COUNTRYMAN has returned from Oakland, Cal., to Denver, Colo.

J. W. NEILL of Salt Lake City, Utah, is in Butte, Mont., on mining business.

J. G. CUSHING of Tonopah, Nev., is in San Francisco, Cal., on mining business.

T. EWING of Los Angeles, Cal., is in San Francisco, Cal., on mining business.

W. MATHEWS has resigned as superintendent of the May Day mine near Eureka, Utah.

P. L. WILLIAMS JR. is superintendent of the Highland Boy mines at Bingham, Utah.

C. L. MORRIS is smelter superintendent of the Highland Boy mines at Bingham, Utah.

T. S. WOOD of Leadville, Colo., interested in Colorado mines, is in San Francisco, Cal.

O. J. SALISBURY of Salt Lake City, Utah, interested in Utah mines, is in San Francisco, Cal.

G. L. CARR of Carrville, Trinity county, Cal., interested in Trinity county mines, is in San Francisco, Cal.

J. B. WATSON of Salt Lake City, Utah, has gone to Brazil, South America, to make mine examinations.

G. M. PINNEY returned to San Francisco, Cal., from a trip to Minneapolis, Minn., on mining business.

D. P. ROHLFING of Salt Lake City, Utah, is manager of the Gold Hunter mine, near Mullan, Idaho.

C. C. WARNER of Bisbee, Ariz., is assistant superintendent of the Copper Queen mine at Bisbee, Ariz.

A. MORGAN succeeds P. E. Murray as superintendent of the Zubiate M. Co., near La Colorada, Sonora, Mex.

J. GEAREN of Wallace, Idaho, is superintendent of the Gold Hunter mine, near Mullan, Shoshone county, Idaho.

C. H. WELLMAN, manager Wellman-Seaver-Morgan Co., has returned from Denver, Colo., to Cleveland, Ohio.

H. W. TURNER, E. M., of San Francisco, Cal., has gone to Bohemia, Douglas county, Oregon, to examine mines.

M. L. REQUA of San Francisco, Cal., is at copper mines in which he is interested near Ely, White Pine county, Nev.

F. W. BRADLEY AND J. H. MACKENZIE of San Francisco, Cal., have gone to Nevada to make mine examinations.

L. E. DUBOIS of Butte, Mont., is manager of the Red Berg M. Co., operating near Basin, Jefferson county, Mont.

W. S. KEYES of San Francisco, Cal., goes to the State of Sinaloa, Mexico, to note mining progress in that vicinity.

J. L. SHINN, superintendent of the Utica G. M. Co., has returned to Angels, Cal., from a trip to San Francisco, Cal.

BERT C. AUSTIN, formerly assistant to F. W. Bradley, is now assistant superintendent at the Oneida mine, Jackson, Cal.

D. P. RHOLFING of Salt Lake City, Utah, is manager of the Gold Hunter lead mines in the Cœur d'Alene district, Idaho.

JOHN LAWLER, owner of the Hillside mine, Yavapai county, Ariz., has returned to Prescott, Ariz., from San Francisco, Cal.

L. GINGER, president of the Gold Coin M. Co. at San Javier, Sonora, Mexico, returned last week from Colorado Springs, Colo.

F. A. MANLEY has closed his office in Boise, Idaho, and is now chief engineer of the Union Pacific Coal Co., Rock Springs, Wyo.

J. T. HODSON, manager of the Lincoln mine, near Pearl, Idaho, returned to camp last week from Salt Lake City, Utah.

D. R. OLIVER of San Francisco, Cal., president of the Zubiate M. Co., is at the company's mines at Zubiate, Sonora, Mexico.

J. L. BRYSON has resigned as superintendent of El Oro mines at Maybert, Nevada county, Cal., and is in San Francisco, Cal.

M. W. MATHER, superintendent of the Plumbago mine at Alleghany, Sierra county, Cal., is in San Francisco, Cal., on mining business.

G. B. EARNSHAW, former superintendent of the Shawmut mine, and builder of the Shawmut mill at Bingham, Utah, is located at Nogales, Ariz.

F. J. HARD of Portland, Or., who controls the Vesuvius, Riverside and Oregon-Colorado mines at Bohemia, Or., is in the East on mining business.

H. W. STEVENS, general manager of Picacho Blanco M. Co., Morristown, Arizona, has returned from San Francisco, Cal., accompanied by his bride.

C. I. DAVENPORT, assistant manager of the Ruby G. & C. Co., of La Batamote, Sonora, Mexico, has gone to Oaxaca, Mexico, inspecting mining properties.

A. H. BUCK, E. M., until recently manager of the Sunset M. Co. at Maguarichic, Chihuahua, Mexico, is in Honduras, Central America, on mining business.

T. F. SINGISER, president of the American Flag M. Co., operating at Park City, Utah, returned to Salt Lake City, Utah, last week from Sioux City, Iowa.

P. JOHNSON, manager of the Alaska S. & R. Co., which is building a plant on Prince of Wales Island, is visiting Chicago and other Eastern points on business.

HERBERT C. HOOVER, E. M., of the firm of Bewick, Moreing & Co. of London, England, with extensive mining interests in Australia, is in San Francisco, Cal.

C. L. LOGUE, formerly chief chemist of the Anaconda copper refinery, Anaconda, Mont., is now head assayer and chemist for the Taylor & Brunton Ore Co., Butte, Mont.

J. H. HAMMOND of the Guggenheim Exploration Co. will move his headquarters to Salt Lake City, Utah. He has been examining mines near Kennett, Sbasta county, Cal., the past week.

WALDEMAR LINDGREN, E. M., of the U. S. Geological Survey, is in San Francisco, Cal., having returned this week from Victoria, Australia, where he has been in the interests of Bewick, Moreing & Co., of London, Eng.

N. S. BRADEN, formerly manager of the Westinghouse E. & M. Co.'s office at Cleveland, O., has been appointed sales manager of the new Canadian Westinghouse Co., Ltd., and assumed the duties of that office Jan. 1, 1904.

E. C. VOORHIES, of Sutter Creek, Cal., owner of the Sutter Creek Reduction Works, has been appointed by the President a member of the U. S. Assay Commission for 1904, which will test the weight and fineness of coins produced at the mints of the United States during the year.

GENERAL GEO. L. GILLESPIE, Chief of Engineers, succeeds General A. P. Chaffee as Assistant Chief of Staff United States Army, with the rank of Major-General, the first time that an officer of the United States Corps of Engineers has been in the line of supreme command of the army in eighty years.

WM. P. MILLER, JR., for a number of years superintendent of the city branch of the Selby Smelting & Lead Co., of San Francisco, Cal., has resigned that position to accept one in Mexico with the San Louis M. Co., at San Dimas, Durango. Mr. Miller, before his departure, was presented with a pair of field glasses by the employes of the company, in token of their esteem.

Obituary.

ARCHIBALD NEVINS, a mining engineer of Grass Valley, Cal., died Jan. 7th of pneumonia at Snowball, Ariz., where he was examining mines for Oakland, Cal., men. Deceased last summer returned to California from Corea, where he was connected with the Oriental Con. M. Co. He was a native of Nevada county, Cal., and is survived by a wife and two children.

C. W. THOMPSON of Tacoma, Wash., manager of the Tacoma Steel Co. which is preparing to build a steel plant at West Tacoma, was drowned by the wreck of the steamer Clallam at Puget Sound, Wash., on the 9th inst. Deceased was also president of the Washington Co-operative M. Syndicate and of the Montezuma M. Co., which are developing coal mines at Fairfax, Wash.

H. H. SWANEY, of Seattle, Wash., a former iron and steel manufacturer of Pittsburg, Pa., was drowned by the wreck of the steamer Clallam on Puget Sound, Wash., on the 9th inst. He was en route to Victoria, B. C., to complete the purchase of iron mines in which Pittsburg men were interested. Five years ago Swaney et al. erected a blast furnace plant at Irondale, near Port Townsend, Wash.

Commercial Paragraphs.

THE Brown Corliss Engine Co., Corliss, Wis., have an order from the Passaic Steel Co. of Paterson, N. J., for a 24 & 44x36 inch tandem rolling mill engine.

A. E. LINDROOTH, SHUBART & CO., who have been representing the Link Belt Machinery Co. the past six years in Denver, Colo., and who are also representing the Goodman Manufacturing Co. of Chicago, have moved their offices from the ground floor of the Boston building to rooms 121-22-23 of same building.

THE American Spiral Pipe Works, 1173-1201 South Paulina street, Chicago, have furnished 44,000 feet for 250 pounds working pressure to the Newhouse mines and smelters, Frisco, Utah; 2500 feet for 325 pounds working pressure to the Kimberly-Montana G. M. Co., Gardiner, Mont., and 7000 feet for 150 pounds working pressure to the Telluride Power Co., Provo, Utah.

THE East End Boiler Works, Desner & Ritchie, 11-19 St. Aubin avenue, Detroit, Mich., have acquired the entire sale and manufacturing of the Detroit water tube boiler from the Detroit Water Tube Boiler Co.; the construction of the boiler will have the personal supervision of Messrs. Desner & Ritchie, either for stationary or marine purposes, and of any capacity. Catalogue will be mailed on application.

BENJAMIN GUGGENHEIM of New York, a member of the well-known firm of M. Guggenheim's Sons, having acquired a controlling interest in the Holthoff Machinery Co., which has been merged with the Loomis-Pettibone Gas Machinery Co. under the new corporate name of Power and Mining Machinery Co., of which Mr. Guggenheim is the president, a prominent officer of the company writes: "By this change we secure unlimited capital, and have the benefit of Mr. Guggenheim's long experience in the requirements of mining, milling and smelting from his connection, for years, with the American Smelting & Refining Co. and the Guggenheim Exploration Co. We are largely increasing our plant and are prepared to furnish not only complete mining, milling and smelting plants, as heretofore, but, in addition, Loomis-Pettibone gas plants and the American Crossly gas engines, of which over 2,000,000 H. P. are now in use. With our increased facilities we shall be able to fill orders promptly and shall continue to manufacture only machinery of the highest grade as to workmanship and efficiency. Messrs. Holtboff and Leuzarder, the original organizers of this company, still retain their interest and connection therewith, and the business will be conducted on the same lines as in the past."

Trade Treatises.

Catalogue A, of the Browning Engineering Co., of Cleveland, O., with branch offices at New York, Chicago and Pittsburg, describes and illustrates their make of locomotive cranes, overhead traveling cranes, I-beam, jib, and other styles of cranes and material handlers.

Catalogue No. 6, third edition, issued by Harron, Rickard & McCone, 21-23 Fremont street, San Francisco, Cal., treats of the Huntington centrifugal roller quartz mill, and such machinery as would be used in mining in connection therewith. The old geared under driven mill and the new style overhead direct driven mill are both illustrated and described in detail. The pamphlet is of standard size, handsomely printed, and deserves a place in a mine manager's working library.

Bulletins 1, 2, 3, 4, 5, issued by the Mine & Smelter Supply Co., Denver, Colo., describing respectively the Dimmick classifier, swinging platform switch, Durkee electric rock drill, Wilfley slime table and No. 5 Wilfley concentrator, give detailed and illustrated description of each in compact form. Any of these publications may be had upon request addressed to the Denver office or any of their branch establishments at Salt Lake City, Utah, El Paso, Texas, City of Mexico, Mexico, or 139 Liberty St., New York City.

Pamphlet L-26-A, issued by the Laidlaw-Dunn-Gordon Co. of 114 Liberty St., New York City, describes the Cincinnati air and gas compressors. One of the compressors is described as being of a new type, in that the air cylinders are provided both with mechanically moved valves and with poppet valves, all points in the compression cycle being determined by the mechanically moved valves, with the exception of the opening of the exhaust, which is determined by the poppet valves. The booklet will be sent upon request.

Catalogue No. 21 of the W. S. Tyler Co., Cleveland, Ohio, is one of the most complete and attractive of the kind ever issued by wire cloth manufacturers. Manifest care has been taken in the preparation of this work; it is especially featured by stating the size of opening in all meshes, which with the decimal size of wire are valuable helps in the selection of screens. Half-tone reproductions of different styles are drawn exactly to scale, and the catalogue contains illustrations of the uses of woven wire cloth which are practical. The book will be mailed to mining men and those interested in screen information by sending their address to the company, Cleveland, Ohio.

Latest Market Reports.

SAN FRANCISCO, January 15, 1904.

METALS.

SILVER.—Per oz., Troy: London, 27⅛d (standard ounce, 925 fine); New York, bar silvor, 58⅝c, refined (1000 fine); San Francisco, 58⅝c; Mexican dollars, 43@45c San Francisco, 45c New York.

COPPER. — New York: Standard, $12.75; Lako, 1 to 3 casks, $13.00; Electrolytic, 1 to 3 casks, $12.87½; Casting, 1 to 3 casks, $12.75; San Francisco: $15.00. Mill copper plates, $17.00; bars, 18@24c. London: £59 5s spot per ton.

Copper is again showing a strong rising tondoncy. It is stated that Calumet & Hecla has contracted to sell 4,000,000 pounds at 13 cents. The prospect of war in the Orient is also aiding in creating a strongor price, and consumors aro buying more freely.

LEAD. — Now York, $4.55; Salt Lako City, $3.50; St. Louis, $4.25 San Francisco, $4.50, carload lots; 4½c 1000 to 4000 lbs.; pipo 6½, sheet 7, bar 5⅞c: pig, $4.75. London: £11 12s 6d ₱ long ton.

SPELTER.—New York, $5.10; St. Louis, $5.00; London, £21 15s ₱ ton; San Francisco, ton lots, 6¾c; 100-lb. lots, 7c.

TIN.—New York, pig, $29.25 @ 29.50; San Francisco, ton lots, 31c; 500 lbs., 31½c; 200 lbs., 32c; less, 32½o; bar tin, ₱ lb., 35@37½c. London, £133 15s.

PLATINUM. — San Francisco, crude, $18.00 ₱ oz.; New York, ingot, $19.00 ₱ Troy oz. Platinum ware, 75 @ 82c ₱ gram.

QUICKSILVER. — New York, $46.50@47.00, large lots; London, £8 7s 6d; San Francisco, local, $44@44.50 ₱ flask of 76½ lbs.; Donver, $48.00. Export, $42.00@42.50.

BABBITT METAL.—San Francisco, No. 1, 10c; No. 2, 7c; No. 3, 6½c; extra, 17½c; genuine, 31½c; Eclipse, 35c.

SOLDER. — Half-and-half, 100-lb. lots, 20.00c; San Francisco, Plumbers', 100-lb. lots, 16.80c.

ZINC.—Metallic, chemically pure, ₱ lb., 50c; dust, ₱ lb., 10c; sulphate, ₱ lb., .04c.

NICKEL.—New York, 50@60c ₱ lb.; ton lots, 40@47c.

ALUMINUM.—New York, No. 1, 99% pure ingots, 35c; No. 2, 90%, 30@34c.

LUMBER. — (Retail): Pine, ordinary sizes, $24.00@25.00; extra sizes higher; redwood, $28.00@30.00; lath, 4 feet, $4.50 @5.00; pickets, $21.00; shingles, $2.50 for No. 1 and $2.25 for No. 2; shakes, $13.50 for split and $15.00 for sawed; rustic, $28.00 @35.00.

NAILS.—Per keg (list prices): No. 20d to 60d, Wire, $3.35; Cut, $3.55; 10d to 16d, Wire, $3.45; Cut, $3.35; 8d Wire, $3.50; Cut, $3.50; 6d and 7d, Wire, $3.60; Cut, $3.60: 4 and 5d, Wire, $3.70; Cut, $3.70; 3d, Wire, $3.85; Cut, $3.85; 2d, Wire, $4.10; Cut, $4.10. Special rates for carload lots.

LIME.—Santa Cruz, $1.25 country, $1.25 city ₱ bbl.

CEMENT.—Imported, $2.25@2.50 ₱ bbl.; California carload lots, $2.00 f. o. b. at works; small lots, $2.25 ₱ bbl. in sacks, 4 sacks to bbl.

STRUCTURAL MATERIALS.

IRON.—Pittsburg, Bessemer pig, $13.85 @14.10; gray forge, $12.85; San Francisco, bar, 3c ₱ lb., 3½c in small quantities.

STEEL. — Bessemer billets, Pittsburg, $23.00@23.00; open hearth billets, $23.00 @23.00; San Francisco, bar, 7c to 12c ₱ lb.

GENERAL SUPPLIES.

ANTIMONY. — New York, Cookson's, 7c; Hallett's, 6½c; San Francisco, 1000-lb. lots, 8c; 300@500-lbs., 8½c; 100-lb. lots, 10½c.

POWDER.—F. o. b. San Francisco: No. 1, 70% nitro-glycerine, per lb., in carload lots, 15½c; less than one ton, 17½c. No. 1*, 60%, carload lots, 13½c; less than one ton, 15½c. No. 1** 50%, carload lots, 11½c; less than one ton, 13½c. No. 2, 40%, carload lots, 10c; less than one ton, 12c. No. 2, 35%, carload lots, 9½c; less than one ton, 11½c. No. 2** 30%, carload lots, 9c; less than one ton, 11c. Black blasting powder in carload lots, minimum car 728 kegs, $1.50 per keg; less car lots, $2.00 per keg.

CAPS.—3x, $5.50 per 1000; 4x, $6.50; 5x $8; Lion, $9, in lots not less than 1000.

FUSE. –Triple tape, $3.60 per 1000 feet; double tape, $3.00; single tape, $2.65; Hemp, $2.10; Cement No. 2, $3.00; Cement No. 1, $2.65, in lots of 3000 feet and up.

CANDLES.—Granite 6s, 16 oz., 40s., 11½c ₱ set; 14 oz., 40s., 10c.

CHEMICALS. — Cyanide of potassium, 98%-99%, jobbing, 23@24c ₱ lb.; carloads, 23@23½c; in tins, 30c; soda ash, $2.00 ₱ 100 lbs.; hyposulphite of soda, 3@3½c per lb.; caustic soda, in drums, 3@3½c ₱ lb.; Cal. s. soda, bbls., $1.20@1.40 ₱ 100 lbs.; sks., $1.05; chlorate of potash, 12@13c; nitrate of potash, bbls., 10c; caustic potash, 10c in 40-lb. tins; roll sulphur, 2½@2¾c; powdered sulpbur, 2@3c; flour sulpbur, French, 3½@3¾c; alum, $2.00@2.25; California refined, 1¾@2c; sulphido of iron, 8c ₱ lb.; copper sulphate, 5¼@5¾c; chlorido of lime, spot, $2.50@2.75; sulphuric acid, in carboys, 66% B, 1¾@2c ₱ lb.: nitric acid, carboys, 8c ₱ lb.

BONE ASH.—Extra No. 1, 5@6c ₱ lb. No. 1, 4@5c.

COAL. — San Francisco, coast, yard prices: Wellington, $8.00; Seattle, $6.50; Coos Bay, $5.50; Southfield, $8.00. Cargo lots, Eastern and foreign: Wallsond, $7.50; Brymbo, $7.50; Pennsylvania, hd., $14.00; Scotch, $8.00; Cumberland, $13.00; Cannel, $8.50; Welsh Anthracito, $13.00; Rock Springs, $11.50, long ton; Colorado Anthracito, $14.00. Coko, $10.50 por ton in bulk, $13.00 in sacks; Sunnyside, $11.50, long ton.

OILS.—Linseed, boiled, bbl., 45c; cs., 50c; raw, bbl., 43c; cs., 48c; Lucol oil boiled, bbl., 44c; cs., 49c; raw, bbl., 42c; cs., 47c. Kerosene—Poarl, per gal., 21½c; Astral, 21½c; Star, 21½c; Extra Star, 25½c; Eocene, 24½c; Elaine, 27½c; Water White, in bulk, 15c; Mineral Seal, iron bbls., 19c; woodon bbls., 21½c; cs., 25c; Mineral Sporm, cs., 26½c.; Deodorized Stove Gasoline, bulk, 17c; do., cs., 23½c; 86° Gasoline, bulk, 25c; do., cs., 31c; 83° Naphtba or Benzine, deodorized, in bulk, per gal., 13c; do., in cs., 19½c; Lard Oil, E W. S., bbl., 85c; cs., 90c; Neats-foot Oil, pure, bbl., 75c; cs., 80c; Sperm, crude, 50@55c; Natural White, 70c; Bleached, do., 75c; Whale Oil, cs., 50@55c.

WHITE LEAD.—Per lb., in kegs: 500 lbs. and over at one purchase, per lb., 6½c; less than 500 lbs., per lb., 7c; in 25-lb. tin pails, ½c ₱ lb. above keg price; in 1 and 5-lb tin cans, 100 lbs. per caso, ½c. per lb. above keg price. Dry Load—In bbls., 1 ton and over, 6½c; do. in kegs, 7c.

RED LEAD.—500 lbs. and over at one purchase, ₱ lb., 6½c; less than 500 lbs., 7c.

LITHARGE.—Pure, in 25-lb. bags, 8@9c ₱ lb.

BORAX.—Concentrated, 6@7c ₱ lb; powdered, 8@10c; fused, 20@25c; crystal, 7c; calcined, 25c.

MANGANESE.—Pure, ₱ lb., 60c.

SODIUM.—Metal, ₱ lb., $1.00.

BISMUTH.—Subnitrate, ₱ lb., $1.75.

MERCURY.—Bichloride, ₱ lb., 90c.

MOLYBDENUM.—$2.00 ₱ lb.

CHROMIUM.—90% and over, ₱ lb., $1.00.

PHOSPHORUS.—American, ₱ lb., 75c.

SILVER.—Chloride, ₱ oz., 90c@$1.00; nitrate, 55c.

ALUMINUM.—No. 1., 99%, small lots, 37c ₱ lb.; 100 lbs., 35c; 1000 lbs, 34c; ton lots and over, 33c, Pittsburg. No. 2, 90%, small lots, 34c; ton lots and over, 31c, Pittsburg.

URANIUM.—Oxide, ₱ lb., $3.50.

(These prices are wholesale, f. o. b. San Francisco, unless otherwise noted.)

New Patents.

DEWEY, STRONG & CO.'S SCIENTIFIC PRESS PATENT AGENCY, 330 Market St., S. F., has official reports of the following U. S. patents issued to Pacific Coast inventors:

FOR THE WEEK ENDING JANUARY 5, 1904.

748,687.—GAS GENERATOR—F. H. Bates, S. F.

748,688.—RAILWAY SWITCH—W. J. Bell, Los Angeles, Cal.

748,692.—BURIAL CASKET—W. C. Booth, Elmhurst, Cal.

748,696.—SOLAR HEATER—J. M. Browning, Jr., Corona, Cal.

749,026.—GARMENT FASTENER—J. C. Christensen, Santa Rosa, Cal.

749,028.—MUSIC TURNER—J. W. Collier, Riverside, Cal.

748,845.—WATER HEATER—J. F. Connell, Los Angeles, Cal.

748,848.—DOOR OPENER AND CLOSER—Driechman Bros., S. F.

748,591.—THIRD RAIL COVER—H. F. Duffy, Seattle, Wash.

748,592.—THIRD RAIL PROTECTOR—H. F. Duffy, Seattle, Wash.

748,710.—CASTING FISH NETS—L. Einarson, Seattle, Wash.

748,714.—MARLINE SPIKE—H. Fesenfeld, Hoqulam, Wash.

748,690.—BOLSTER—G. J. Friend, Kingsley, Or.

748,850.—DISH WASHING MACHINE—J. H. Griswold, Oakland, Cal.

748,862.—OIL BURNER—C. A. Hammel, Los Angeles, Cal.

748,868.—BED BOTTOM—J. Hoey, S. F.

748,732.—OPTICAL FRAME—C. L. Hogue, S. F.

748,737.—CULTIVATOR—T. J. Huhheil, Los Angeles, Cal.

749,141.—BOOK SUPPORT—A. D. Irving, Los Angeles, Cal.

748,741.—GRAIN SHOE—J. T. Jardine, Paso Robles, Cal.

748,757.—WAVE MOTOR—J. A. Langstroth, Oakland, Cal.

748,072.—LIFTING JACK—M. M. Moore, Sr., Santa Barbara, Cal.

748,875.—MALT TURNER—J. Mueller, Seattle, Wash.

749,090.—RAKER GAUGE—J. P. Olson, Tacoma, Wash.

748,790.—SWAGE GAUGE—A. O. Reppeto, Blacbly, Or.

748,732.—DRAFTING GARMENTS—J. Rohbert, S. F.

748,804.—DREDGER—Smyth & Bowers, S. F.

748,819.—CONCENTRATOR—L. Tulloch, Angeles, Cal.

748,820.—STAMP MILL.—L. Tulloch, Angels, Cal.

748,670.—GATE HINGE—J. H. Vandever, Olalla, Or.

748,896.—VEHICLE BRAKE—W. U. Wadsworth, Sutter City, Cal.

748,897.—OIL BURNER—J. A. Walkley, Los Angeles, Cal.

749,122.—PAPER BINDER—R. G. Whitlock, Los Angeles, Cal.

748,678.—TURBINE—H. Wolke, S. F.

Notices of Recent Patents.

Among the patents recently obtained through Dewey, Strong & Co.'s SCIENTIFIC PRESS U. S. and Foreign Patent Agency, the following are worthy of special mention:

DISH WASHING MACHINES.—No. 748,850. Jan. 5, 1904. J. H. Griswold, Oakland, Cal. This invention consists of a containing tunk having closed sides, bottom and ends, and so suspended in a fixed structure that it may be oscillated or tilted in the direction of its length. Trays or baskets of wire mesh or other equivalent open work are placed in the ends of this tunk and a sufficient amount of water for washing purposes. Between the luner ends of the baskets are located hinged swinging gates, the fulcrums of which extend across the tub, and the gates incline downwardly and inwardly, so that their lower edges rest upon the bottom of the tub. The tub, when free to be tilted from one side to the other, will cause the water to move alternately from end to end and through the trays containing the articles to be washed.

VEHICLE BRAKE.—No. 748,896. Jan. 5, 1904. W. W. Wadsworth, Sutter City, Cal. This invention relates to an improved brake for wheels of traveling harvesters and the like. It consists of a band brake partially encircling the periphery of the wheel normally out of contact therewith and means by which the brake is applied by a frictional device which is actuated by the rotation of the wheel itself.

BED OR COUCH BOTTOM.—No. 748,868. Jan. 5, 1904. John Hoey, San Francisco, Cal. This invention relates to improvements in bed and couch bottoms in which an elastic cable or wire support for the upper mattress is attached to a framework, which framework, usually termed the "bed bottom," is supported upon the bedstead. The object of the invention is to stiffen and strengthen the fabric comprising the bed bottom and to maintain the edges in their proper position, also to provide a means for regulating the tension where the fabric is composed of elastic cables extending across the frame upon which they are supported.

MECHANICAL DOOR OPENING OR CLOSING DEVICES.—No. 748,848. Jan. 5, 1904. W. F. Driesehmun and J. Drieschman, San Francisco, Cal. This invention relates to a device for mechanically opening and closing doors which are located at a distance from the point where the operation is conducted, such as street doors leading up flights of stairs to rooms or flats located at the head of the stairs. It consists in a mechanism which may be operated from the head of the stairs or other distant point and by which the latch of the door is first retracted, leaving the door free, and the door is afterward opened by a further movement of the mechanism.

SITUATIONS WANTED.

A SOBER, INDUSTRIOUS YOUNG MAN DESIRES a situation as Surveyor, Assayer, Druughtsman und Bookkeeper. Has bad three years' technical training and four years' practical experience in gold and quicksilver. Am conversant with tbe estimation of ore and the preparation of maps and reports. Best of references as to ability and character. Address "M.," care of this office.

A YOUNG MINING ENGINEER DESIRES position as assistant; assayer and good draughtsman; State licensed surveyor for California. Address C. R., care Min. and Scientific Press.

A YOUNG MINING ENGINEER DESIRES POsition as Superintendent. Successful in handling men. Up to date and practical. Practiced in obtaining highest bullion output at least cost hy milling, cyaniding and concentrating. Speaks Spanish and is conversant with Mexican laws and customs. References required and given. Address "Engineer," care of Mining and Scientific Press, San Francisco, Cal.

AS ELECTRICIAN WITH MINING COMPANY; nine years of experience operating polyphase, hydro-electric power plants and direct current machinery; can make all repairs; age 26 years. First-class references; will go anywhere. F. P., this office.

ASSAYER AND CHEMIST DESIRES POSITION in mine or laboratory. Address V. H., this office.

EXPERIENCED SUPERINTENDENT, ENGIneer, Metallurgist; technically and liberally educated; 15 years handling men and machinery of smelters, mills and mines. See testimonials. Address Prof. Stickney, Mountain View, Cal.

EXPERIENCED MILLMAN WISHES POSItion. Address Box 202, Enterprise, Cal.

HIGH-GRADE MAN WILL ACCEPT MODERate salary. **PRACTICAL MINE FOREMAN and All Round SUPERINTENDENT.** Inquiries cheerfully answered. Address "Wire Cable," Sonora, California.

MANAGER LARGE GOLD MINING AND milling company in Arizona desires to change his location and obtain similar position with desirable company elsewhere. Best of references from present employers. Address I. C., this office.

MILL AND SMELTER SUPERINTENDENT, at present disengaged, wisbes similar position with responsible company; college graduate with varied experience. Best of credentials furnished and required. Address "Gluckauf," care tbis office

MINING ENGINEER, AGE 20, FIRST-CLASS Surveyor and Assayer, four years in Colorado and two in South America, desires position as engineer or asst. superintendent. J. E. B., this office.

POSITION WANTED BY NEW YORK ELECtrical engineer with Pacific Coast company. Experienced in construction work and selling. A position where he can work into tbe selling end preferred. References from company with which he is now connected. Address G. P., this office.

SUPERINTENDENT IS OPEN FOR POSITION to develop gold or copper properties; experienced miner; can make underground maps and models, also do the assaying; speaks Spanish; good references from past companies. Address "Develop," care this office.

WANTED, POSITION AS SUPERINTENDENT or Manager of "Gold Mining Property;" 12 years' experience in practical mining, also assayer, mine surveying and drafting. Will furnish surveying and drafting instruments, and will accept 50% of salary in stock in a "Good Mining Co." O F. Matkin, care of Concentrator, C. C. C. Co., Cananea, Sonora, Mexico.

WANTED—POSITION WITH MINING COMpany as manager or assistant. Examinations, surveying, assaying; also familiar with drift and hydraulic mining. Best of references. Address W. H. J., this office.

WANTED, POSITION BY MACHINIST AND Engineer; efficient in steam, electricity and compressed air; seven years' experience at mines; good references. Address Box 54, care of Mining and Scientific Press.

WANTED—POSITION AS SUPERINTENDENT or assistant of copper mines and smelters; competent all round man, good assayer, analyst and draughtsman; can handle labor; speaks Spanish. Address "Smelter," care this office.

YOUNG MAN WITH SOME EXPERIENCE and training in chemistry, metallurgy and general engineering, wants work at mine or any place where he can get additional experience and training. Address "Espanol," care of this office.

HENRY CAREY BAIRD & CO.,
Industrial Publishers, Booksellers and Importers,
810 Walnut St., Philadelphia, Pa., U. S. A.

☞ *Our New and Revised Catalogue of Practical and Scientific Books, 92 pages, 8vo.; a Catalogue of Books on Metallurgy, Mining, Prospecting, Mineralogy, Geology, Assaying, Analysis, etc ; a Catalogue of Books on Steam and the Steam Engine, Machinery, etc.; a Catalogue of Books on Sanitary Science, Gas Fitting, Plumbing, etc.; and our other Catalogues and Circulars, the whole covering every branch of Science applied to the Arts, sent free and free of postage to any one in any part of the world who will furnish his address.*

OSBORN'S PROSPECTOR'S FIELD-BOOK AND GUIDE.

Sixth Edition, Revised and Enlarged.

PUBLISHED DECEMBER 16, 1903.

The Prospector's Field-Book and Guide in the Search for and the Easy Determination of Ores and Other Useful Minerals. By Prof. H. S. Osborn, LL.D., Author of "A Practical Manual of Minerals, Mines and Mining." Illustrated by 66 engravings. Sixth edition, thoroughly revised and enlarged. 370 pages, 12mo.

☞ *Price $1.50 by mail free of postage to any address in the world.*

CONTENTS.—Chapter I. Preparatory Instruction. II. The Blow-Pipe and Its Uses. III. Crystallography. IV. Surveying. V. Analyses of Ores. VI. Special Mineralogy. Gold. VII. Tellurium, Platinum, Silver. VIII. Copper. IX. Lead and Tin. X. Zinc and Iron. XI. Mercury, Bismuth, Nickel, Cobalt and Cadmium. XII. Aluminum, Antimony, Manganese. XIII. Various Useful Minerals. XIV. Petroleum, Ozocerite, Asphalt, Peat. XV. Gems and Precious Stones.

APPENDIX.—Prospecting by means of Electricity; Weights and Measures of Various Nations; How to find the Specific Gravity; Specific Gravity of Metals, Ores, Rocks, etc.; Ores Associated with Gold and Silver; Other Ores; Specific Gravity of Minerals of Common Occurrence; Average in Cubic Feet of a ton weight of Various Materials; Assay of Gold by the Touchstone; Estimation of Gold in Alloys; Standard Value of Gold in Different Countries; Power for Mills; Boring; Diamond Drill; The Chemical Elements, Their Symbols, Equivalents and Specific Gravities; To find the Proportional Parts by Weight of the Elements of any Substance whose Chemical Formula is known; Common Names of Chemical Substances; Prospectors' Pointers; Glossary of Terms used in connection with Prospecting, Mining, Mineralogy, Geology, Etc. Index.

☞ *An elaborate circular showing the full Table o Contents and specimens of the engravings of this impor ant and popular book will be sent to any one in any part of the world who will furnish his address.*

WE ALSO PUBLISH:

Orton.—Underground Treasures: How and Where to Find Them. A Key for the Ready Determination of all the Useful Minerals within the United States. By James Orton, A. M., late Professor of Natural History in Vassar College, N. Y., etc. A New Edition with an Appendix on Ore Deposits and Testing Minerals with the Blow-Pipe. Illustrated. Price.....$1.50

Osborn.—A Practical Manual of Minerals, Mines and Mining: Comprising Suggestions as to Localities and the Associations of all the Useful Minerals. Full descriptions of the Most Effective Methods of Both the Qualitative and Quantitative Analyses of Each of these Minerals and Hints upon the Various Operations of Mining, including Architecture and Construction. By Prof. H. S. Osborn, LL.D. Illustrated by 171 engravings. Second edition, revised and enlarged. 393 pages, 8vo. Price $4.50

Lieber.—The Assayer's Guide: or, Practical Directions to Assayers, Miners and Smelters, for Tests and Assays, by Heat and by Wet Processes of the Ores of all the Principal Metals, of Gold and Silver Coins and Alloys, and of Coal, etc. By Oscar M. Lieber. A new, revised and enlarged edition. Illustrated. 283 pages, 12mo. Price.....$1.50

Erni and Brown.—Mineralogy Simplified: Easy Methods of Identifying Minerals, Including One by Means of the Blow-Pipe, by Flame Reactions, by Humid Chemical Analysis, etc. A new and revised edition, 411 pages, illustrated by 90 engravings. Pocket-book form, morocco, gilt edges. Price.....$2.50

Duncan.—The Practical Surveyor's Guide: Containing the necessary information to make any person of common capacity a finished land surveyor, without the aid of a teacher. By Andrew Duncan, Land Surveyor and Civil Engineer. A new, revised and greatly enlarged edition. Illustrated by 72 engravings, 214 pages, 12mo. Price.....$1.50

☞ *By mail free of postage at the publication prices to any address in the world.*

☞ *Illustrated Circulars giving full tables of contents of the above books sent free of postage to any one in any part of the world sending his address.*

WANTED.

WANTED, BY WORKING CYANIDER,

Quantity low grade gold ore, sand, or slimes, who wishes to work same on royalty or will put working plant on same for interest in property. Send description to Frank G. Cline, Gold Hill, New Mex.

Paint

For pile and wharf work there never was a paint that gave so much satisfaction as P & B Paint.

P & B Paint penetrates the pile and preserves its fibres against the attacks of marine pests, such as Teredo and Limnoria and when used in conjunction with P & B Pile Covering is a perfect protection for all pile work.

Send for booklet.

Works: Carnegie, Pa.

EUREKA CONSOLIDATED DRIFT MINING Company.—Location of principal place of business, San Francisco, California; location of works, Placer County, California.

Notice is hereby given, that at a meeting of the Board of Directors, held on Tuesday, the 12th day of January, 1904, an assessment (No. 39) of one-half (½) cent per share was levied upon the capital stock of the corporation, payable immediately in United States gold coin, to the secretary, at the office of the company, Room 3, No. 214 Pine street, San Francisco, California.

Any stock upon which this assessment shall remain unpaid on the 13th day of February, 1904, will be delinquent, and advertised for sale at public auction; and, unless payment is made before, will be sold on MONDAY, the 7th day of March, 1904, to pay the delinquent assessment, together with the costs of advertising and expenses of sale.

By order of the Board of Directors.

CHAS. W. DIXON, Secretary pro tem.

Office—Room 3, No. 214 Pine street, San Francisco, California.

TANANA MINING COMPANY—LOCATION OF principal place of business, San Francisco, California.

Notice is hereby given, that at a meeting of the Board of Directors, held on the 11th day of December, 1903, an assessment (No. 7) of four (4) cents per share was levied upon the capital stock of the corporation, payable immediately in United States gold coin, to the secretary, at his office, Rooms 404-405 of the Call Building, San Francisco, California.

Any stock upon which this assessment shall remain unpaid on the 18th day of January, 1904, will be delinquent, and advertised for sale at public auction; and, unless payment is made before, will be sold on MONDAY, the 29th day of February, 1904, to pay the delinquent assessment, together with costs of advertising and expenses of sale.

By order of the Board of Directors.

EDWARD H. STEARNS, Secretary.

Office—Rooms 404-405, Call Building, San Francisco, California.

NEW! USEFUL! PRACTICAL!

ROGERS'

Machinists' Library.

In announcing the completion of

ROGERS' MACHINISTS' LIBRARY

the publishers emphatically claim that the hooks form the best home-study and reference works published on

Machine-Shop and Drawing-Room Practice.

1204 Pages, 1244 Illustrations and 3023 Index References.

1. ROGERS' "PROGRESSIVE MACHINIST," $2
2. ROGERS' "ADVANCED MACHINIST"...$2
3. ROGERS' "DRAWING AND DESIGN"...$3

EACH VOLUME IS COMPLETE IN ITSELF AND MAY BE OBTAINED SEPARATELY.

The hooks are beautifully hound in black vellum, with gold edges, and with titles stamped in gold.

PATENTS

Our U. S. and Foreign Patent Agency presents many and important advantages as a Home Agency over all others, by reason of long establishment, great experience, our Washington branch which tends *exclusively* to our business before the Patent Office, intimate acquaintance with the subjects of inventions in our own community, and our most extensive reference library, containing official American reports since 1790, with full copies of U. S. Patents since 1872. All worthy inventions patented through DEWEY, STRONG & Co.'s Patent Agency will have the benefit of a description in the *Mining and Scientific Press*. We transact every branch of patent business, and obtain patents in all countries which grant protection to inventors. The large majority of U. S. and foreign patents issued to inventors on the Pacific Coa t have been obtained through our agency. We are conservative and counsel preliminary examinations in cases of doubtful novelty. Guide to inventors sent on request.

DEWEY, STRONG & CO.

Prospecting Equipment.

The needs of a prospector and miner when he begins the development of a new claim are usnally determined by the extent of his experience, his ingenuity and the fullness of his purse. Often he may have an extended experience, a fund of inventive and constructive ability, but very little capital with which to begin business at the new mine. The average new mine, if not a "tunnel proposition," generally requires a shaft, and one is started promptly, usually on the vein and at a point where the best ore discovered crops out. The pit soon passes beyond the shoveling stage, and then a hoisting apparatus of some sort becomes a necessity. The old time-tried, but reliable, windlass is nsually the first plant set up, and by its use the shaft may be continued downward 50 or 60 feet, or even more. This sort of work is both laborious and slow, and while the miner may be willing to work untiringly at drilling holes in the rock, at filling the bucket below, and in the various other kinds of hard labor to be done in a shaft, he begrudges the time and labor spent at the windlass, and, if a horse can be obtained by any means, he proceeds to "rig up" an outfit to hoist with a whim, whip or some other sort of device which will dispense with manual labor and save time. He realizes that his capital consists chiefly of time and knowledge, and it is his aim to utilize both to the best advantage. A result of a new prospect shaft is always an unknown quantity, but usnally it does not at first justify an elaborate outlay of money in equipment, no matter what may be the subsequent outcome of the property. An elaborate head-frame may be dispensed with until the value of the prospect is proven to an extent snfficient to justify it. A simple tripod may be made to do good service for some time with a horse whim or whip. One of the accompanying illustrations represents a prospect shaft equipped with a head-frame consisting of four pieces of timber, two of them being arranged as a pair and secnred together to hold the top and bottom winding sheaves in place. The other two are disposed as shown, forming a "three-legged" frame, which will meet ordinary requirements. The shaft is provided with doors, which are opened and closed at the will of the man at the brake. The doors are balanced by counter-weights, and these evidently consist of large rocks in sacks. One of these weights overhangs the manway compartment, which is the only unworkmanlike thing observable about the works, for should the rope holding the counter-weight break, the rocks would, in all probability, go down the manway, which is uncovered. The entire equipment shows how simple, and still how complete, such a plant can be made, with a little mechanical skill and ingennity in arranging details, making everything to operate with the least possible effort on the part of the topman.

A Prospector's Hoisting Equipment.

The other illustration is that of the Petticoat mine in Calaveras county, Cal. This shaft was originally started with a windlass, but outgrew that primitive equipment. The head frame is of the four-post construction, so commonly seen at California mines, and which has so little beyond stability and rigidness to recommend it. There is a large amount of material in this head frame that is not really essential to either strength or the economical operation of the mine. A frame of two posts, with back braces to take the thrust, and with anxiliary braces from the posts to the angle braces, with the customary cross ties and cap, are all that are necessary in such a construction, but the four-post frame is one of the most commonly noticed of all the various types about metal mines, and the strange thing about it is that they are still being constructed by those professing to be mechanical engineers. A study of the strains to which a head frame are subjected will show that the resultant between the rope in the shaft and the one on the hoisting reel will fall where a line bisects the angle between the two lines of a rope. The frame should be so constructed that this line of thrust should fall just inside of the back angle brace, but the four-post frame is easy to build, and being very strong when made of sound material of liberal dimensions, all engineering features are disregarded.

A Four-Post Head Frame.

Prosperity in Mexico.

The investment of American capital in Mexican mines, and in other industries in that Republic, is assuming such large proportions as to attract more than passing notice from the foremost men of that country. The past decade has seen a greater invasion of Mexico by American capital, American miners, methods and machinery, than in all the past. The result is that old, time-honored ideas and customs are giving place to energetic, go-ahead Americanism and enterprise. Another ten years will find English as commonly spoken as Spanish in that Republic, for the influx of Americans is on the increase, and it will, without doubt, continue, for Mexico, though nearly 400 years old, is still fertile in resources of many kinds, and the opportunities for those with capital, energy and experience are considerable. This fact is being more fully appreciated in the United States with each successive year. Under the direction of President Diaz the Republic has prospered as never before, and he has rendered investment in Mexico safe, for prior to his succession to the presidency in 1884 it cannot be said that this was the case. The mines of Mexico have produced enormous amounts of silver and gold in the past by methods considered primitive and unsatisfactory in these days of modern scientific practice, but those results were accomplished under different conditions from those obtaining under American administration. The arrastra, the patio and the crude furnace will give place to the stamp mill, the pan and the modern smelter. But Mexico's mines will be developed and continue to yield great fortunes. Nor will it all be done by Americans, for the Mexican engineers have caught the American spirit of advancement and Mexican capital is also being freely expended in development of the mineral industry in that Republic.

THE cost of mining operations in every branch of the business should be ascertained by the manager, and this can only be accomplished by the employment of efficient men to supervise each branch of the work, together with a comprehensive, common-sense system of bookkeeping. It is only by inaugurating and maintaining such a system that the best results may be accomplished.

New Development in Africa.

The annual report of the Tanganyika Concessions, Ltd., of London, Eng., was submitted to the directors of that company at a recent meeting. The company was organized to explore and develop the mineral resources of the Congo Free State in equatorial Africa. The name of the company is derived from a large lake, which is one of the sources of the Congo river. The principal explorations have been carried on in the Katanga, a division of the Congo State occupying its southeastern portion. The reports state that gold has been discovered in Katanga in sandstone, along a ridge which outcrops for 1000 feet in length. Some of the samples contain gold, it is claimed, to the extent of $24, but only about half of it is in free state. The streams of the region are also said to be gold bearing. Most of the gold in the sandstone, which is understood to be a ferruginous quartzite, is very fine, though coarse gold is found in the placers. The report also states that large deposits of copper have been partially developed and that the outlook is favorable. There is little doubt of the great possibilities of central Africa. From Cape Colony to Egypt, there is a succession of mineral fields. Some of these are known to the world, and others doubtless remain to be discovered. Kimberly, the Rand and Rhodesia are already famous. What may yet come out of the Congo country can only be surmised, but the indications are that the mineral belt will be found to continue in a northerly direction wherever mountains occur in the line of its course. Stanley and other travelers mention the occurrence of copper ore in the region tributary to Arruwimi river, a northern tributary of the Congo, several hundred miles northerly from the Katanga field, which is another connecting link in the chain "from the Cape to Cairo."

Power Equipment.

When equipping a mine the mistake is too often made of providing too little power, or, rather, not taking into consideration the probable increase in power that may be required. Particularly is this the case with boilers. Abundant boiler capacity is always advisable, if not absolutely necessary. Boilers occasionally require repairs, and in such instance if there be but one boiler, work depending on power must come to a standstill until the repairs can be made and steam once more is available. This alone illustrates the advisability of more than one boiler. Occasionally the mistake is made of placing a large engine in connection with a small boiler. While, under proper conditions, a large engine is more economical than a small one, a large engine cannot be snecessfully operated by a boiler supplying insufficient steam. It is a safe proposition to provide for at least double the boiler capacity that seems necessary at the start, and to put in such engines as may be required for the work in progress, and that may be reasonably anticipated. In the case of shaft sinking, for instance, a 20 H. P. boiler and a small double cylinder hoist, of about 15 H. P., will put the shaft down 700 to 800 feet, hoisting 1000 to 1200 pounds of rock at a load and at slow speed, possibly somewhat more, but it is not economy to work any machinery to the full limit of its capacity. The above instance assumes no unusual event; that little water is encountered, and that drilling is done by hand. In the event of a large flow of water being struck and pumps required, then the power would soon become inefficient. If power drills are to be employed, the compressor to be run by steam, the boiler capacity must be at least doubled for shaft sinking alone. Ventilating fans must be run, air must be supplied to the forges, and this takes considerable power. It may be desirable to run a small dynamo to furnish light, or to run some small machinery about the mine, above or below the ground, or a saw and timber framer may be required. There are always contingencies arising where it is desirable and economical to employ power. It is well enough to start with a power plant suited to present needs, but everything should be arranged in such a manner that additions may be made at the least expense and inconvenience. This refers to construction and location of buildings, space for extended foundations of boilers, etc. If a very deep shaft is contemplated it is not advisable to place at the shaft a large and expensive hoisting plant, with corresponding power equipment to sink the first few hundred or a thousand feet, but to supply machinery calculated to economically do the work to a depth of say 900 or 1000 feet, and to locate this temporary plant so that it will not interfere with the subsequent construction of the large head frame or the location of permanent hoisting and power plant. In some instances the temporary hoist is located opposite the end of the shaft, and in others on the opposite side from the site chosen for the permanent plant, but it may be placed on the same side as the latter if proper calculations be made for the placing of the permanent plant in the future. The topographical situation, or the expense of constructing suitable foundations, are the most important factors to be considered in such cases. The proper power equipment of a mine is as important and requires as much forethought and careful planning as does the method of operating the mine in the most economical manner.

IT is reported that the Standard Oil Co. has formed an alliance with the Rothschilds to control the copper market of the world. The combination, it is said, also contemplates absorbing the Heinze interest at Butte, Mont. The consolidation will be important factors in Spain, Chile, Montana, British Columbia, Mexico and Michigan, and will wield an important influence in the copper market. If the price of copper advances as a result of this combination, the opening of new copper mines in the various parts of the world that are not now known to have an existence will be sure to follow. There are large undeveloped copper resources in Arizona, Utah, Nevada, Alaska, Mexico, South America, central Africa and many other places, and the new consolidation will have to either absorb these, sharing a more or less profitable business with them, or place the price of the metal at a figure so low that the majority of them cannot afford to operate. The combination would be undoubtedly the most important that was ever formed to control copper.

Grubstake Partnerships.

Grubstaking is an old-time institution among miners and prospectors, and many good properties have been discovered by men out on a grubstake. The custom of grubstaking is recognized by the courts as a sort of partnership, in which both parties to the contract—usually unwritten—are protected in their rights. When contracts or agreements of this nature are entered into, it is customary for one party to supply the necessary tools, provisions and other supplies to the extent of a stated amount, or during a certain period. The prospector, being the other party, agrees to industriously prospect a stated region, or he may have a roving commission to seek where he may please. The agreement may only extend to the discovery and location of a mineral vein, or may go further and include its development to a stated depth or condition, or during a stipulated time. Probably no two partnerships so formed are identical in their conditions, but they are perfectly legal, just, and not infrequently prove to result fortunately to those interested. In the inception of such contracts the prospector may insist upon the one putting up the "grub" and outfit, supplying all of these things prior to his starting out on the venture. If he finds nothing during the life of the agreement the outfitter can only look upon his investment as a loss. Should the prospector find a valuable mine after the termination of the agreement, he is not bound by law, or in any other way, to give an interest to his former partner, but, on the other hand, the prospector may take no unfair advantage of his partner and convert to his own exclusive use any value he may obtain from the property. There is a difference between pure "grubstake" agreements and those where a miner is employed at a stipulated salary or by some fixed agreement to find a developed and paying mine. In the latter there is usually a fixed limit to the amount the miner shall receive as a commission or reward for his effort, but in the grubstake partnership each may enjoy the benefits of the venture to the full extent of their individual interest in the proposition, as previously determined by the agreement.

OFFICERS of British colonies in Australia and New Zealand have sent formal messages to the authorities of the Transvaal, South Africa, warning that country against the importation of Chinese laborers for the mines and railways there, and foretelling grave consequences if the evident intention be carried out. The experience of the United States, British Columbia, Australia and New Zealand with the Chinese, it would seem, should furnish sufficient data upon which to make it possible to formulate conditions under which Chinese may be safely allowed to enter the Transvaal as laborers. The commissioner who some months ago visited America with a view to studying the Chinese situation in the United States and British Columbia, upon his return to South Africa proposed a set of conditions under which he thought the Chinese might be safely admitted. These conditions were essentially: That the term of service be fixed; the class of work at which he shall be employed shall be predetermined; hours of labor to be stipulated; he can under no circumstances engage in trade; he shall not own land or vested property; and his return to China upon the expiration of his term of service shall be compulsory, unless he voluntarily determines to renew his term of service if permitted to do so. These conditions make him a non-entity. How the Chinese can socially, financially or politically affect conditions in the Transvaal under these terms, if he accepts them, it is difficult to understand.

THE present condition of the oil industry in the San Joaquin valley of California shows clearly that unorganized individual producers cannot successfully compete with large and perfectly organized companies holding large tracts of oil land. It is predicted, however, that those who have the means to hold their property until better conditions present themselves will profit largely in the end.

CONCENTRATES.

THE melting point of pure lead is 326° C. or 619° F., and that of tin is 231° C. or 448° F. An alloy of 68 parts tin and 32 parts lead melts at 180° C. or 356° F.

✤✤✤✤

COPPER is often associated with tin stone in veins, notably in the Cornish tin mines. Gold occurs with tin oxide in some of the tin-bearing veins of South Dakota.

✤✤✤✤

THE clay found in mine gouge often contains little or no alumina, being composed almost wholly of finely ground quartz, lime and other constituents of the vein.

✤✤✤✤

SELENIUM is often present with the telluride minerals. It may be detected when heated by the peculiar odor produced, resembling that of decaying horseradish.

✤✤✤✤

AN extended description of the lead-silver mines of the Coeur d'Alene district of Idaho was published in the MINING AND SCIENTIFIC PRESS in the issues of January 3, 10 and 17, 1903.

✤✤✤✤

TO MAKE a success of prospecting, the prospector should have a knowledge of mineralogy and also of geology. These can best be had by studying good texthooks on these subjects.

✤✤✤✤

THE title to a mining claim sold by an alien who had located the same is good if the alien became a citizen of the United States or announced his intention to become such hefore selling the claim.

✤✤✤✤

A MINE OWNER cannot drive a tunnel from his own claim through that of an adjoining location to reach property owned by him situated heyond. Mining is not recognized as a public utility, and a right of way cannot bo condemned through the property of others.

✤✤✤✤

CLAY consists chiefly of silicate of alumina, but usually also contains lime, iron oxide, etc., as well as more or less silicic acid uncombined with other elements. The silicate of alumina also constitutes a large portion of some slates, pumice stone and of fuller's earth.

✤✤✤✤

MILL MEN customarily hurn tin mill screens before tacking them on to the frame, bot it is not universally in practice. Where the tin is not thus removed, it is found that the sharp, cutting grains of quartz splashed against the screen keep the screen apertures free from amalgam.

✤✤✤✤

WHERE placer gold is found on top of a local "coment" depost in a gulch, it is reasonable to expect to find gold on the real bedrock underlying tho cemented gravel. This cannot bo depended upon absolutely, hut the possibility of tho occurrenco of gold on bedrock should be investigated.

✤✤✤✤

FREESTONE is a name given to homogeneous sandstones, evidently deposited in deep water, showing little or no sign of hedding and breaking with equal facility in any direction. In the Eastern United States it is largely usod in the facing of huildings. Its color is dull brown. It is of Triassic age.

✤✤✤✤

OWING to the formation of an infusihle oxido upon its surface, aluminum is difficultly fosible. It foses mere easily than silver bot less readily than tin or zinc, its point of fusion being 655° C. It is most readily bent and rolled betweeu 100° and 150° C. The specific gravity of the metal is 2.7; that of quartz 2.6.

✤✤✤✤

THE current price of molybdenum in New York City is $2 per pound. Molybdenite, tho solphide of the metal, contains 60% molybdenum. A ton of clean concentrated molybdenite would then be worth theoretically $2400. Transportation and reduction charges most be deducted, and of these latter Concentrates is not informed.

✤✤✤✤

MARSH GAS is inflammable, and is a simple compound of carhon and hydrogen. It is found in marshy places. It is probably due to a collection of gas of this character heneath the ice of the pond in Kansas, that hurns upon being afforded a vent through the ice. The "natural gas" associated with oil sands is of different character.

✤✤✤✤

THE climate along the coast of Alaska is characterized by mild winters and cool summers. The lowest temporature recorded at Sitka is 3° F. below zero, and at Juneau 4° F. below. The Ketchikan region is 300 miles south of Sitka and has a milder climate. Nearer the ranges of the interior the cold is greater, sometimes falling to 15° F. below zero.

✤✤✤✤

THE mineral sample from Ashland, Or., is quartz in what was originally (before alteration) grano-diorite. The visiblo minerals are quartz, feldspar, hornblende, chlorite (altered from hornblende) pyrite, chalcopyrite (copper sulphide) and pyrrhotite, a sob-sulphide of iron. Gold and silver may also be present. This can he determined hy assay.

✤✤✤✤

THE rock specimen from Fort Bayard, N. M., is graywacke, an aggregate of quartz grains cemented by silica and lime. The black color is largely due to carbonaceous matter. The name graywacke is of German origin and is applied to compact sedimentary grit rocks, composed of grains of quartz, feldspar, slaty material, etc. The term is almost obsolete in American petrography.

✤✤✤✤

MACHINE DRILLS are sometimes operated by steam. All of the first machine drills made were steam drills, hut compressed air is more satisfactory for several reasons. The metal does not expand and contract with air, as is the case where steam is used; the men work with more comfort and with little danger, and the air exhausted into the mine workings assists ventilation.

✤✤✤✤

A TON of ordinary quartzose ore in place in the mine measures 13 cubic feet; when broken, about 20 feet. The waste broken in mine work weighs nearly the same as the quartz, under similar conditions. Coosequently, thirteen tons of waste will practically fill the space originally occupied by twonty tons of ore. Two-thirds of a ton of waste will occupy the space taken by a ton of oro in place.

✤✤✤✤

WITHIN largo masses of ore there are sometimes observed narrow zones or vein-liko occurrences, due to the fracture and croshing of the rocks, and this small zono of fracture is foond to contain ore far richer and ofteu of different character from that of tho main mass within which it occors. This is doe to secondary deposition of mineral and an enrichment within this zone of croshing, where superior opportunity has boen afforded for ere deposition.

✤✤✤✤

THE word "bonanza" is of Spanish origin and means literally "fair weather," but has boceme a common term for a "rich strike" or a rich ore hody. "Borrasca" is the opposite of bonanza and means "bad weather." "Busconcs" in Mexico are "searchers," or more liberally translated, "prospectors." The same term is applied to those who explore old abandoued mines to get out of them such ore as they can obtain oither to work or te sell.

✤✤✤✤

A MINING CLAIM located in this month of January does not require any assessment work during the year 1904, nuless a local or State law demands it. What constitutes $100 worth of work depends to a great extent upon local custom. At one time a shaft 10 fect deep or a tunnel 10 feet long represented $100 worth of labor, but there are many places where a 10-foot drift can be run for $25 or $30, and a 10-foot shaft sunk for less than $50, as well as places where it costs upward of $100 to sink a single foot in a medium-sized shaft, owing to tho hardness of the rock.

✤✤✤✤

THE locator of a water right must stato on his notice of location the amount of water claimod, but if he does not take out and utilize all he claims, and other persons take up rights at a lower point on the stream, the prior locator cannot subsequontly increase the quantity he has been using by increasing the size of his ditch or otherwise if it is done to the detriment of thoso below him on the same stream. The first locator may claim all the water flowing in the stream at the point of appropriation, but be must take out and employ all he claims at tho beginning.

✤✤✤✤

ONE of the mineral specimens from Daggett, Cal., is colemanito (calcium borate), and is similar to tho mineral mined at Borate, in the eastern part of the Calico range, San Bernardino county, Cal. The specimen marked No. 2 is celestite (sulphato of strontium), with calcite and quartz crystals. The celestite is the bluo crystals. The calcite is the softer of the white crystals. In the present condition the celestito is only valuable as a cabinet specimen. It is omployed in tho manufacture of "red firo" in pyrotecbnics. The pulverized mineral gives a strong red color to the blowpipe flame.

✤✤✤✤

THAT there is any material difference between a "fissure veiu" and a "true fissure" vein is not apparent. Those fissures associated with intrusivo dikes are probably of the most deep-seated origin, as the dike rock came from a sphero not within tho possibility of human invention or genius to roach. A dike may be assumed to indicate great depth of fissure, hot cannot be considered an index of size of vein or of value of contents. A dike which appears at one part of a vein is sometimes observed to loave the vein. It is generally possihle to determine by careful examiuation whether the dike or the vein be the older, when the two are sitoated side by side.

✤✤✤✤

WHERE it is found necessary to place a head frame on a side hill at the collar of a shaft, and the engine below the shaft on the slope of the hill, the head frame may be held in position by being anchored down with heavy weights. To accomplish this a space must be graded oot hehind the shaft for the head framo which may be huilt in any desired shape, hut instead of back hraces to take the resultant strain, after the usual type, the sills most extend backward away from the shaft, and angle pieces run from the hoad frame to the sills. This hack portion may thon be weighted down with old railroad iron, old shoes and dies from stamp mills, or any other iron, or hoavy rocks to the amount of twenty to thirty tons, depending on the load it is intended to raise in the shaft, and also on tho leverage the hoad frame may afford to the draft of the hoist. The Argonaut mine, near Jackson, Cal., was equipped with a head frame in the position above described in 1894, and has given satisfaction. In some instances, instead of angle pieces of wood, heavy iron rods or chains are substituted to take the strain.

✤✤✤✤

THERE are few concentraters in the gold mills on the Witwatersrand, Sooth Africa. The ore is treated by amalgamation in the usual manner, with a rather coarse screen to secure large capacity. The tailings are then run to the cyanide plants and treated direct without roasting or other previous manipulation. As a result the tailings contain generally a valuo that in the Western United States is considered good enough to cyanide, and such tailings are treated at a profit. The average Western mill man naturally inclines to the belief that he could extract higher values from the Rand ores at the expense of a somewhat lower capacity, but with a better economic showing for the company.

✤✤✤✤

ALUMINUM is extracted from its ores by means of the electric current. Formerly it was obtained by fusing the double chloride of alumina with sodium. The chlorine united with the sodium leaving the aluminum in metallic state. Aluminum is not attacked by boiling nitric acid, though nearly all other metals, except gold and platinom, are. Hydrochloric acid, which will not dissolve gold or platinum, attacks aluminum readily, forming aluminum chlorido, with evolution of hydrogen. Whoo aluminum is treated with mercoric chlorido (corrosive soblimate) tho surface bccomes coated with mercury and if imuersed in water at an ordinary temperature will decompose it with violence. Massive aluminom oxidizes only superficially, but its powder burns with great rapidity liko that of magnesiom with groat heat.

✤✤✤✤

"CONCENTRATES" is weekly in recoipt of a large number of questions which require research into almost every departmont of the modern sciences connected oithor directly or indirectly with tho industry of mining and of metallurgy. As has been heretofore stated herein, to print both questions of corrospondents and the answers as well would take a large amount of space, some of which can possibly be put to better use in making replios to the various queries. The following from Butte, Mont., is one of the varieus questions asked, and, being of a somewhat complicated nature, it is thought well to print both question and answer, while it also forms an illustration of the space required to print the question alone: "In the early 80's in the Alta mine, at or near Virginia City, Nev., a dam broke away in one of the upper levels and caused such au influx of water into the mine from adjoining properties that tho Alta was flooded from the 2000-foot level to the 1900-foot. On the 2000-foot levol four men were at work in the face of a drift 1000 feet, or possibly more, from the shaft. The only opening from this level to the workings above was tho main working shaft. Tho water filled this level and rose to the 1900-foot level, or 100 feet above. Aftor pumping for the space of about six days the water was lowered below the back of the station at the 2000-foot levol sufficiontly to allow the rescuing party to enter the drift and hring out the men who had been imprisoned in the face thereof. Tho men wore alive at the tiue of beiug relieved and lived some tiue, hot died afterwards, presumably from shock. Assuming that the level had boen driven at the usual per ceut of grade, say .016, the water would, of course, strike the hack of the level at the shaft ond before it would cover the bottom of it at the face, and tho inner end of the drift would be full of air at the time, which would, of course, be compressed as the weight of water increased on the outside. What I wish to learn is, what would be the natural offect on the lungs of the imprisoned miners, and what atmospheric pressure are the lungs of a human being capable of resisting? Also, what are the couditions and arrangements under which men work in the caissons in New York harbor and other places? I have been teld that tho men who work in and under the last-mentioned conditions are subjected to a very high pressure, and that they are brought out by stages and the pressure gradually decreased." The difference in elevation between the 1900 level and the 2000 lovel is practically 100 feet. A column of water 100 feet in height will develop a hydrostatic pressure of 43.4 pounds per square inch. This pressuro is approximately that under which men work in caissons. At the St. Loois, Mo., bridge the pressure at depth in the caisson ranged from 45 to 50 pounds per square inch, corresponding to a depth (theoretically) of about 104 to 115 feet. At the Memphis, Tenn., bridge the maximum pressure was 41 to 43 pounds per sqoare inch. At the Brooklyn, N. Y., bridge the maximum pressure used was about 36 pounds por square inch, though the theoretical pressure required was much higher. This was due to the occurrence of a stratum of stiff clay, which made it possible to work at a much lower pressure in safety than would havo been required had the material been quicksand instead of clay. The maximum pressure in this caisson (36 pounds per square inch) was employed at a depth of 95 feet. Experimonts have been made in taking men out of caissous in stages, but it is not generally the practice. One of the host means yot found to assist the men on coming from the caisson is to hoist them on an elevator to the surface, instead of compelling them to climb a vertical ladder from 40 to 100 feet through a small, poorly ventilated and usoally wet shaft to the surface. The temperature in the caisson varies with the air pressure, and is often as high as 90° under prossures exceeding 45 pounds per square inch.

Improved Chlorination Process for Gold and Silver Ores.

TO THE EDITOR:—Some years ago I had occasion to erect a roasting furnace for chloridizing an ore carrying both gold and silver. the latter predominating. The ore was crushed to 30 mesh—dry stamp mill—and first roasted sweet; then salt and iron sulphide, finely pulverized. were charged in near the discharge end of the furnace. The salt and sulphide were mixed so there was 5% of free sulphur per 100 pounds of the mixture. This material was charged in by means of a long spoon made by splitting a gas pipe along the seam so as to form a trough long enough to reach across the furnace hearth.

The furnace was a mechanically rabbled reverberatory, the rabbles being carried by wheeled carriages at intervals of forty-five seconds. Eighty pounds of ore were charged in with the passage of each carriage, the amount of chloridizing mixture charged being such that the salt equaled 4% of the ore. When charged in—about 9 feet from the discharge—the ore was at a bright red heat and was roasted down to about three-tenths of 1% of sulphur—practically a sweet roast. The mixture was distributed in the charging spoon so that it made an even line across the hearth just in front of the moving carriage and was plowed under and mixed with the ore within two or three seconds after being charged in. This was kept up continually. Within thirty minutes after being mixed with the chloridizing mixture the ore was discharged to a pit under the hearth and allowed to lie about twenty-four hours. The results were good. 90% to 95% of the gold and silver being soluble in a strong solution of "hypo." No apparent gold losses were sustained.

The same year I had occasion to test the siliceous telluride ores of South Dakota. and under the same treatment, despite the greatest care. the gold loss was over 50%, the silver loss being very small. I have also met with similar losses in other localities, so have accepted the fact. as given in various metallurgical works, that roasting gold ores with salt has been a very uncertain operation as to economic results, but very certain to result in abnormal losses.

To overcome this difficulty I conceived the idea of chloridizing the hot, calcined ore in a closed receptacle, using chlorine gas under pressure. In the laboratory this gave very satisfactory results on the ores from South Dakota above referred to.

The apparatus used would hold 5 pounds of hot ore, which was about the capacity of the muffle used for roasting. Chlorine was developed in the usual style and admitted to the chloridizing device under a very slight pressure, the whole being allowed to stand over night. No loss whatever was sustained as far as we could determine by laboratory tests. The extraction by strong "hypo," by cyanide and by amalgamation (grinding in a mortar). was equally good as to both metals, being about 96%. Value of original ore from $13 gold. 18 ounces silver, to $2 to $3 gold, 10 to 30 ounces silver.

The results were so satisfactory that, under the advice of several metallurgists and practical mill men, I took out United States letters patent covering the invention, and, believing it to be of importance to the mining industry, will briefly describe the process as applied to regular mill work.

The sketch herewith shows the end of a common, hand-operated roasting furnace, with a hopper formed in the hearth and close to the finishing end. In this hopper the hot calcines accumulate as desired and are kept hot by their proximity to the firebox.

A series of sheet metal shells or upright cylinders. holding say 2 tons each, are provided and so situated that they can be charged by car through the top. As soon as the charge is in, the top is closed, except a small pet cock. Through pipes at the bottom chlorine gas is forced in. This, being heavier than the air in the ore, fills all of the interstices, completely displacing the air. As soon as the presence of chlorine gas is detected at the top the pet cock is closed and the pressure of chlorine gas continued as may be found necessary. The silver will become rapidly changed to a chloride. Such gold chlorides as form will be at once broken up by the heat to assume other forms, to be again broken up until the gradual reduction of the temperature reaches 180° C., when all the volatile gold will come down as a stable chloride. After this takes place the ore can be safely discharged and will carry with it all the mineral, as none could escape.

Ample provision is made to draw off the excess chlorine and to confine and collect the dust, so that practically nothing is lost. The chloridized ore may be discharged to an ordinary cooling floor and then charged to tanks, pans or barrels, as desired, by manual labor, or, as shown on the sketch herewith. to a cooling and conveying floor, where it is mechanically cooled, conveyed and discharged into the tank or other receptacle.

There are several ways of developing chlorine gas that can be used, but the simplest device would be to use liquid chlorine. This is sold in iron cylinders, pumped to a pressure of from six to twelve atmospheres. is anhydrous and pure. By simply opening a cock any desired amount of gas can be drawn off. and at any required pressure. One pound of liquid chlorine will yield 5.31 cubic feet of gas at 70° F., or a pressure of about two atmospheres at 800° F., which is the temperature of the ore in the chloridizing shell required for rapid chlorination. Supposing the receptacle to contain 40 cubic feet—a capacity of 2 tons of ore. Finely crushed ore represents about 66% of solid and 34% of spaces between the ore particles, or about one-third of the contents to be filled with gas. Two and two-third pounds of liquid chlorine will give 14.54 cubic feet of gas. and at 800° F. a pressure of 14 pounds in the receptacle. This will force out all the free air, practically. and bring every particle of ore in contact with hot chlorine more perfectly than in the roasting furnace, where so much of the gas goes up the stack.

Anhydrous chlorine has no effect on iron except under great heat. The sheet iron receptacles are lined with thin cast iron staves or segments joined with graphite cement. The heat radiated through this lining would not be sufficient to cause any action of the chlorine on the shell, and the gradual decomposition of the cast iron would form a graphite coating that would prevent further action of the gas on the lining.

The cooling can be accomplished by mechanical means if desired, but the preferable practice would be to provide enough receptacles so that by the time they are all filled the first would be ready for discharge and use again. This would be about the only cost in addition to the cost of present mills and would be but trifling compared to the extra saving and the certainty of operating without volatile losses.

The gist of my improvement consists in chloridizing hot ore in a closed receptacle, under pressure, preventing gold losses by confining the volatile products until cooled, so that stable chlorides are formed. The after treatment will be the present practice.

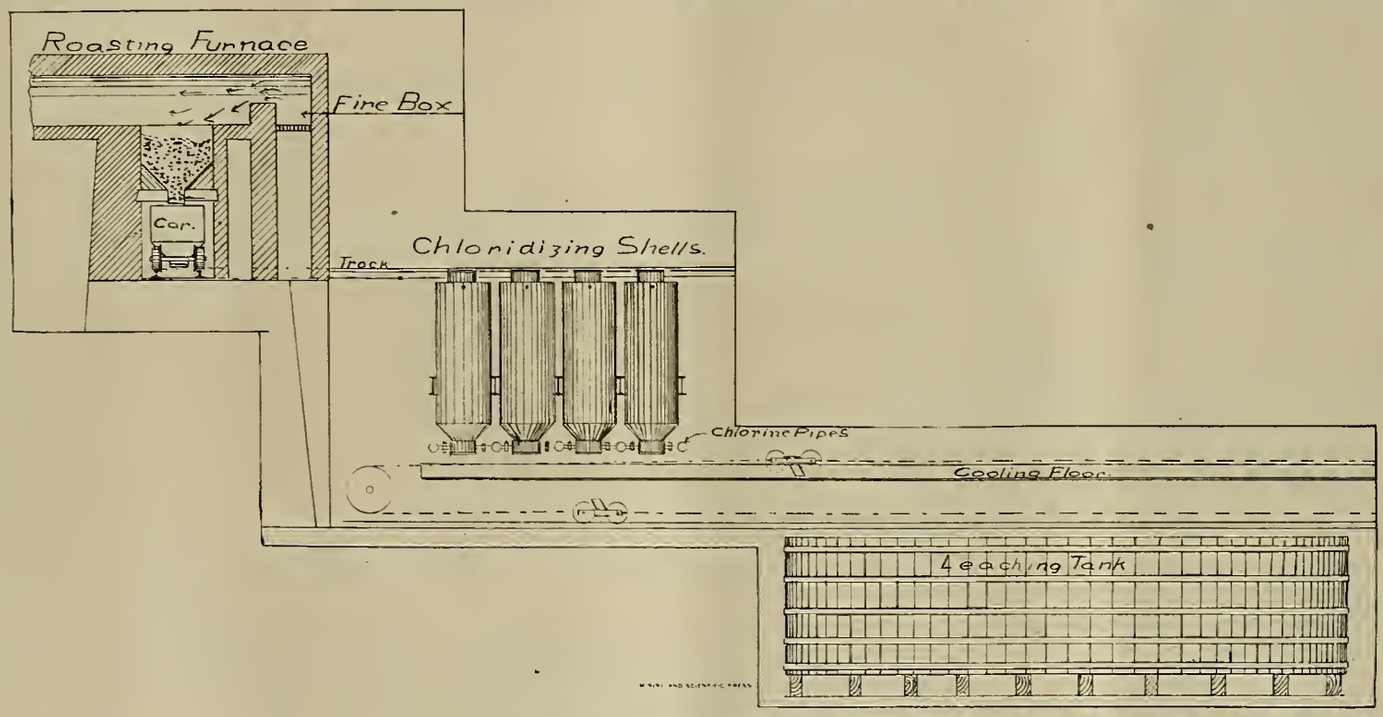
For fine gold and for a prepared chloride of silver, cyanide is a perfect dissolvent, but a poor dissolvent for a natural chloride of silver. A strong solution of "hypo" will dissolve the gold and is a natural dissolvent for silver. Pan amalgamation is often the best possible means for recovering values from chloridized ore. Local conditions and the nature of the material will determine the best means of extraction in all cases.

There are many districts and many mines that produce complex ore so low in grade that no one of the metals will yield a profit, but combined—providing the expense is not increased—the values would be sufficient to bring success. All copper and lead, as well as other base chlorides, can be washed out and recovered as by-products, while the percentage of precious metal values that will be recovered will be greater than under present practice, as no ore can be roasted with salt without 10% to 12% loss of the silver, and usually many times that of gold.

The accompanying sketch simply shows enough to give an idea of the application of the process in a small mill. The method of application to cylinders and other mechanical roasters on a large scale will be apparent without illustration, as the device can easily be adapted to existing construction. A new mill designed for this process could be made very nearly automatic and of any desired capacity.

HORACE F. BROWN.

San Francisco, Cal., Jan. 18.



Plant for Chloridizing Gold-Silver Ores.

Method of Mixing Concrete by Hand.

A tight "mixing" box, about 8 feet long, 4 feet wide and 10 or 12 inches deep, and a platform 9 feet wide, 12 feet long, of ⅞-inch matched boards laid on 2x3-inch pieces, are built and the box is placed beside the platform, says a writer in the Engineering News. The boards forming the long sides of the box and the 2x3-inch pieces of the platform are allowed to project 1 foot on the ends, and are shaped to form handles by which each is easily moved. The cement and sand, properly proportioned, are mixed dry in the box; then water is added, and a fairly "wet" mortar is made. Meanwhile the broken stone or gravel is placed upon the platform in a layer 6 inches thick (being usually measured in a bottomless box), and is thoroughly wet from hose or buckets. The mortar is then cast over the stone in a fairly uniform layer by means of shovels. The mass is then turned over two or three times on the platform by means of the shovels, and thence incorporated into the work. Turning twice on the platform is usually sufficient.

This method gives a thorough mixture and utilizes the laborers to good advantage, a gang of six men being advantageously employed. Two men will prepare the mortar while four men get the stone on to the platform; all hands then finish the operation.

Foundation Bolts for Engines.*

NUMBER II—CONCLUDED.

Fig. 4 illustrates a bolt fitted with a large cast iron washer. It is cored out to receive the square head of the bolt, so that when it is put in place the head cannot turn in the washer, but as the latter is round there is no danger of turning the whole device. Where this form of construction is used care must be taken to set one or more bricks at exactly the right height to hold the nut so that it cannot drop down and out of the washer. After these bricks are set the tops should be covered with cement, then the washer and bolt head are pressed into it until thoroughly imbedded and left to dry. The temptation to omit the cement on account of cost, especially on engine and compressor foundations, and similar work that is soon concealed, appears to be great, consequently some workmen yield to it and lay the bricks nearly dry, as they evidently do not understand the importance of thorough work along this line.

Fig. 4 affords a good hold on the bricks above it,

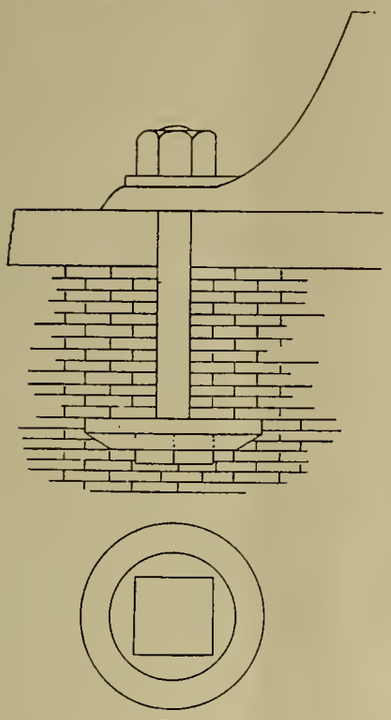


FIG. 4.

but the device shown in Fig 5 is better still, as it represents even more surface. As it is square instead of round, with a square hole cored out for the

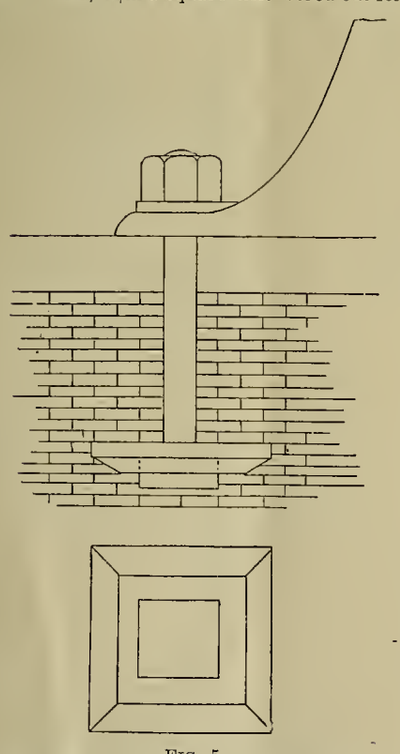

FIG. 5.

bolt head, it is impossible for it to get loose and turn, even if excessive stress is brought to bear on the nut.

Fig. 6 is a superior form of construction, and is accordingly recommended. It is similar to one already illustrated, but in this case the bolt is longer, extending down through the cap stone, including several courses of brick. The pocket made for insert-

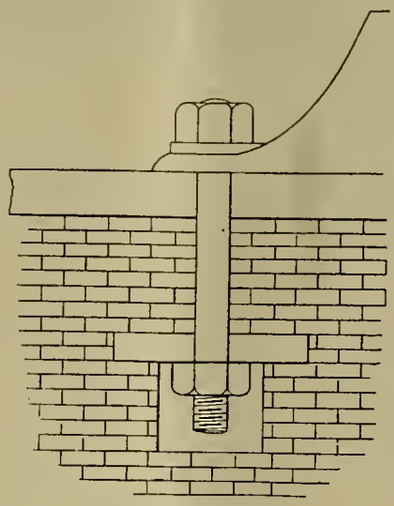

FIG. 6.

ing the nut is covered by a small stone nicely cut so as to afford good bearing surface. It may be good policy to put a washer between this stone and the lower nut as otherwise it will be difficult to turn it, if found necessary to do so. A thin wrought or malleable iron washer will answer every purpose.

If the brick or stone foundation of an engine is allowed to stand for several weeks before the frame is put upon it, and the foundation nuts screwed down solidly, it will give better results than to screw down the nuts and unduly compress the cement or mortar before it is fully dried.

Due examination of these illustrations and careful consideration on the subject cannot fail to show that brick is better than stone for these foundations, because the flat surface presented by the brick allows it to quickly form good joints. It is possible to do nearly as well with stone, provided the extra care required is given to it, and, as a rule, this will not be done unless the engineer watches it coutinually, and declines to approve any work that is not first-class in every respect.

As illustrating this point an incident related by W. E. Crane, M. E., is of interest. Several stone foundations had been put in, that, according to contract, should have been laid solidly in cement, but he feared that the work had not been well done. He called upon the contractor to mix water and cement together, making the mixture thin enough to flow into open crevices, and directed him to fill the foundations full of it. The contractor started all right, but as the work proceeded and barrel after barrel of cement disappeared he objected, claiming that if this was to be continued he would charge extra for all cement used.

A moment's consideration will show that if all space between the stones had been filled with cement in the first case according to agreement, none of the semi-liquid preparation would have flowed into the foundations, therefore the test applied simply exposed fraudulent work.

It is just as easy to cheat on brickwork, for by only partially covering the bricks laid on the inside of a foundation, some of the space is left vacant, thus saving cement for the contractor, but insuring a poor job for the engineer. Such a fraud is more difficult to discover in the case of brickwork, as the outer edges of the brick are nicely plastered over, thus preventing anything from flowing into the vacant spaces.

Such tactics on the part of dishonest contractors make it difficult for honest ones to get work, because it costs more to fill a space with cement than it does to let it remain vacant, therefore the honest contractor must put in a higher bid than his less scrupulous competitor, consequently he does not secure the contract.

The natural consequence is that it is not always wise to award a contract to the lowest bidder, although the public is sure to criticise the action of any official who would favor a higher but more honest bidder on a municipal contract.

Of course it is necessary to employ a competent inspector to oversee the work as it progresses, and promptly condemn any departure from the spirit and letter of the contract. If the men who do such work expected to have charge of the machinery afterwards, there would be less liability of imperfections, but their responsibility ceases when the last brick or stone is laid, and, as trouble develops, the engineer must provide remedies, or else be considered incompetent for the position.

These remarks concerning foundations are not strictly a portion of the subject of foundation bolts, but the two subjects are so closely allied that it is difficult to separate them, for the best bolt ever made could not do good work in a poor foundation.

*W. H. WAKEMAN in Electricity.

A Typical California Quartz Mill.

The accompanying illustration is that of the Washington mill at Bath, a small village near Forest Hill, in Placer county, Cal. The mill is set into the hill on rock terraces, the ore passing through every process in milling by gravity. Bath is the site of the portal of the Paragon channel tunnel. This tunnel runs several miles into the mountain, where it connects with the workings of the Dardanelles mine ou the same channel. The Washington vein lies at contact of serpentine and diorite, and was undoubtedly the source of a portion of the gold found in the Paragon–Dardanelles channels. Boulders of quartz from the vein are found in the channel, which are gold bearing. The mill is located on a steep mountain side, several hundred feet below the top of the Forest Hill divide, and a greater distance above the canyon of the American river which drains the immediate region. There are numerous quartz veins passing under the Forest Hill divide, but only a few of them have been developed to any extent, and still fewer have been equipped with mills, although some of these veins form promising prospects. This is probably due to the fact that drift mining is chiefly carried ou in that vicinity and that these mines, which are among the most extensively operated of this class of mines in the world, locally form a more attractive investment.

Washington Co.'s Mill, Bath, Cal.

GREAT BRITAIN has broken down the bars of conservatism, and has adopted a 50-pound weight in place of the old standard which for centuries past has recognized 112 pounds as a hundred weight. This will greatly simplify the transaction of business with America and other countries employing a decimal system.

IT is said that oxalate of potash in about a 10% solution will make a white mark on a blue print, but in order to keep the solution from running and blurring the print it is suggested that gum arabic be added, forming a mucilaginous fluid.

The "Inverted Saddle" Reefs of the Bendigo Goldfield.*

Written by WM. H. CUNDY.

In the question of the synclinal folds I recognize that it is a large undertaking to confine within the limits of a short paper, and at the same time convey a comprehensive idea of their characteristics, and the importance of their relationship with the anticlinal folds, in the general question of practical mining. However, from a practical point of view, I consider the question of great importance.

It is a generally accepted theory that the rocks on this field were originally laid down in water in horizontal layers, subsequently being bent over, or roughly corrugated, probably by the granite upheaval, as illustrated in the following diagram (Fig. 1) showing the layers or beds of rock as originally deposited, and the same rocks subsequently buckled up. (Fig. 2.)

From the present position of the rocks it is evident that the forces responsible for this buckling exerted a very strong lateral pressure, and it is also evident that there was an endlong pressure as well, for looking at the stratification transversely it will be seen that the undulations (dip) of the rocks are short in comparison with the longer and wave-like undulations (pitch) when viewed longitudinally. (Fig. 3.)

While the process of bending over was in progress, it is natural to assume that the beds or layers of rock would not be of uniform strength and thickness. Consequently, while the anticlinal arch and the synclinal trough were being formed the weaker ones would break. This would more particularly be the case near the surface, where the resistance would not be so great, and this fact (together with considerable faulting) may be laid down as one of the principal reasons why the reefs on the Bendigo field were not earlier recognized as anticlinal, or more commonly known "saddle" reefs.

Local prejudice among mining men would not admit of the principle of the anticlinal formation until recent years, but much more averse were the miners in regard to the synclinal fold formation. Even at the present time there are practical men of over thirty years' experience on the field who deny that

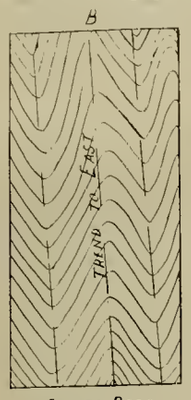

FIG. 2.

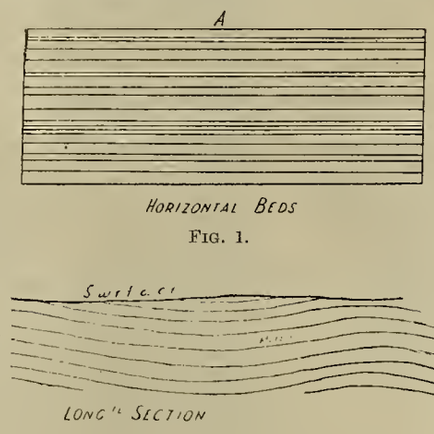

FIG. 1.

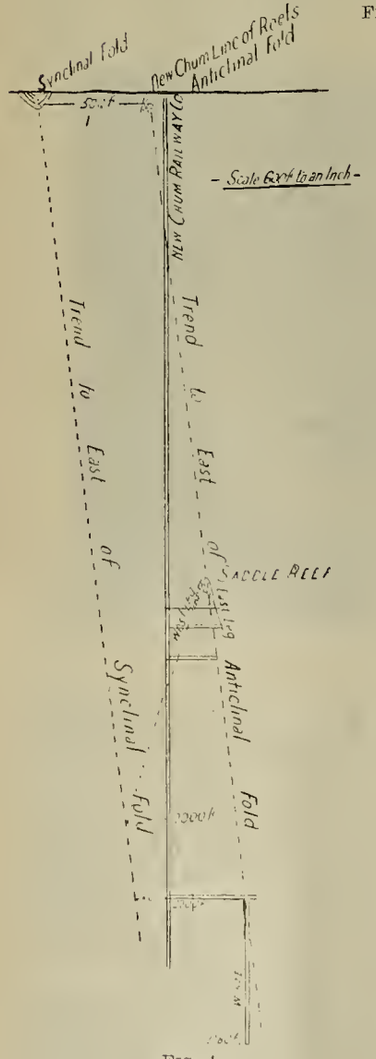

FIG. 4.

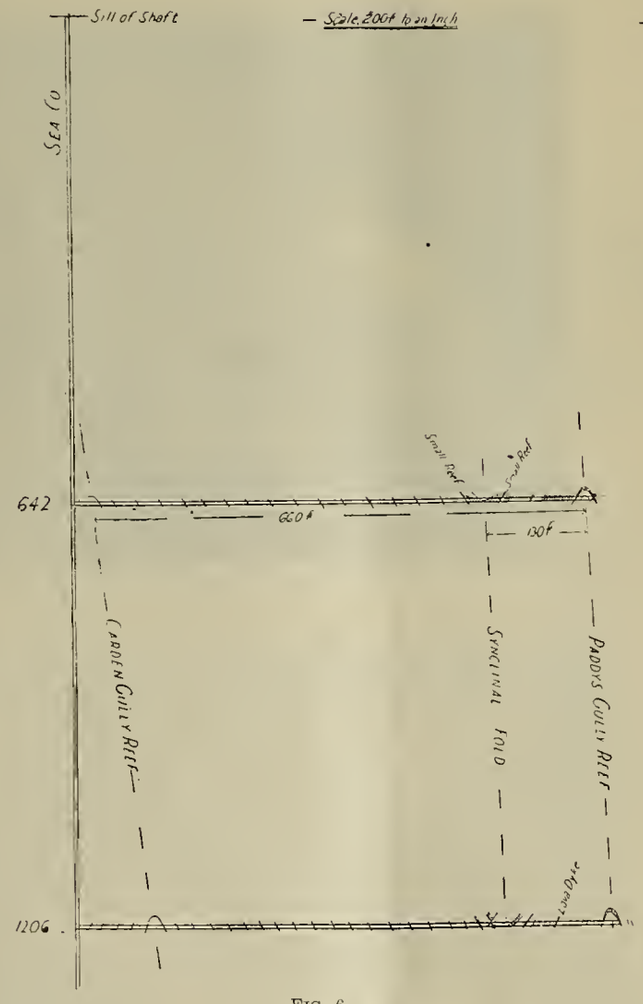

FIG. 6.

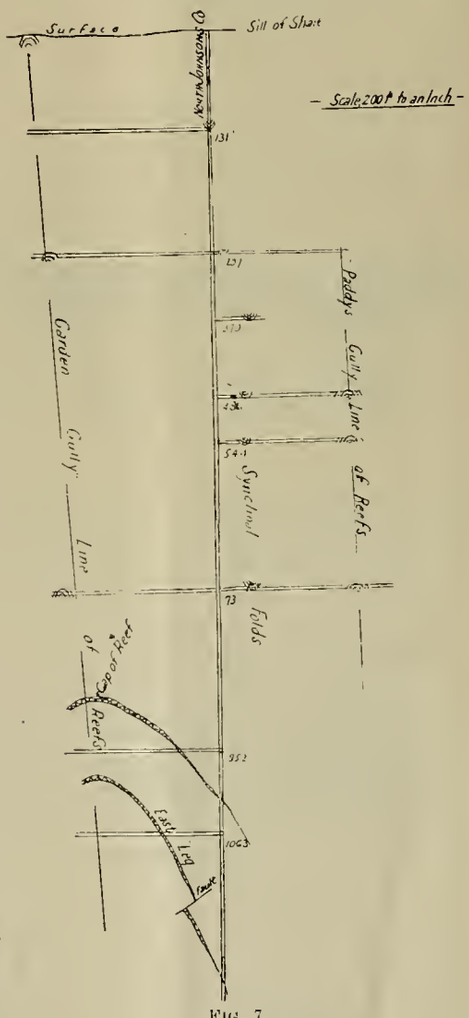

FIG. 7.

* Abstract Trans. Australian Min. Eng.

any synclinal folds exist, simply because they have not seen them in their own mines, and are not sufficiently interested to notice them in others. In the last few years the practical men are evincing a greater desire to become more acquainted with the geological side of the question and applying it to practical mining. This is as it should be, for it stands to reason that without some knowledge of the deposition of the rocks and reefs, the work of laying out systematic mining operations must be attended with a large element of chance.

The result of the geological survey of the Bendigo goldfield, upon which I was engaged some years ago, under the direction of E. J. Dunn, disclosed the fact that transversely in a distance of 2½ miles there are thirteen anticlinal folds along which the saddle reefs are formed, with twelve corresponding synclinal folds between them. The survey comprised an area of 20 square miles, in an oblong strip 2½ miles wide by 8 miles long. The above number of anticlinal and synclinal folds were found within this limit, but it is well known that many others exist both to the east and west of the area surveyed. And further it must be noted that though the reefs were traced for a distance of 8 miles, they continue for miles north and south of that limit. When it is considered that the bulk of the mining operations has been chiefly conducted on only three lines of reefs, the magnitude of this field is apparent, also the immense area yet to be exploited.

The anticlinal and synclinal folds have a general strike of N. 20° W., but they do not at all times run parallel to each other—in places they nearly converge and again widen out. The distances between the anticlinal folds vary from 400 feet to as much as 1600 feet, and the synclinal folds are not always midway between them. For instance, there is a distance of 660 feet between the Garden Gully and Paddy's Gully lines of reef, with the synclinal fold only 130 feet west of Paddy's Gully reef. (Fig. 6.)

The fact must be admitted that where the synclinal reefs have been found they are invariably smaller in comparison with the anticlinal reefs, but it must also be noted that very few have been found, and only in a few instances worked to any extent. This smallness may be accounted for as follows:

When the bending over of the rocks is considered the action would be that the anticlinal folds would leave larger openings or cavities (subsequently filled with quartz), and the tendency would be that any accumulated quartz in the synclinal fold would be smaller, as the rock beds or layers would form so many troughs, one inside the other, the pressure always being downward toward the axes, with an action that would prevent large cavities being formed. There is one at least notable instance where the synclinal reef is a large one, situated 410 feet west of the New Chum line of reef, immediately north of Fortuna battery. This was a well known landmark in the early days, standing some 30 feet above the surface in the form of a pyramid.

Though the synclinal folds can not in all cases be fixed accurately on surface, owing to the rocks not being sufficiently exposed, they have been actually found on surface and at a depth in mines on the following lines of reefs, viz., between the Carshalton and Napoleon lines of anticlinal reefs, between New Chum and Sheepshead lines, between New Chum and Nell Gwynne lines, between Deborah and Garden Gully lines, Garden Gully and Paddy's Gully lines, and Paddy's Gully and Derby lines. So far as I know, the greatest amount of work done on a synclinal reef was that on a line between the Garden Gully and Paddy's Gully's reefs from Landsell's "Sandhurst" shaft, and also from the east shaft of the Koch's Pioneer Co. This reef was more than payable, and it seems almost unaccountable that more work was not done to further exploit the channel of ground north and south of this locality. Another instance where the synclinal reef was worked is at the Johnson's Reef Extended Co.; here it was followed for about 200 feet in length, but was hardly of a payable character.

The general local impression is that the inverted saddle reefs are not auriferous, or, at least, payably so, and that they are small comparatively; but I think this condemnation too sweeping, for it must be remembered that very few have been seen, and very little work done on those that have been found. It may be said also that the synclinal folds have been seen in many places without carrying quartz, and I agree that it is so; but, on the other hand, we have also numerous instances on the field where crosscuts have been driven and the anticlinal center country also found barren of quartz. In such a case, however, a center country winze is sunk and the reef invariably found, but I know of no case where such work has been done to exploit the synclinal country. I have mentioned where the synclinal reef has been successfully worked, which, I think, is sufficient to indicate the importance of searching for them, especially so where the amount of work necessary is small in comparison with that required for prospecting the anticlinal reefs.

From time to time a large amount of information has been gathered to endeavor to trace the same layers of rocks surrounding the auriferous reefs on the one line of reef to other lines of reefs on either side of it. To more clearly convey the importance of this, we will assume that at points A (Fig. 3) we have a rich reef surrounded by certain rocks. To fix the positions of these rocks at points B, C and D might solve the question that as the reefs at A were auriferous, so are those in the same zone of rocks at B, C and D. Though no definite principle has been evolved so far to decide as to the method of tracing these rocks, still some important move has been made in that direction. To actually decide this question, accurate data and close research are necessary, and with this knowledge at hand some definite scheme may be found to be of practical benefit. In this respect we are not likely to gain much information from the composition of the rocks themselves, as A. W. Howitt, in his analytical and microscopical examination of the rocks, taken from surface and at frequent intervals to a depth of 3000 feet, from Lansell's 180 Mine, finds that in actual composition there is no difference between them.

In the course of my work on the field, extending over twelve years, I have collected many examples of the synclinal folds under various circumstances, and purpose giving several of them to illustrate this paper. They are all from actual survey and accurate measurement and will tend to show, in some cases, the practicability of undertaking prospecting work for synclinal reefs at a comparatively small cost. By a glance at Fig 2 it will be seen that successive portions of the anticlinal and synclinal folds are not directly under one another, but have a trend eastward in their downward course of about 10 feet in every 100 feet. Thus as great depths are reached the synclinal folds have been getting nearer to the shafts. The shafts on the Bendigo field have, as a rule, been sunk in close proximity to the anticlinal fold or "center country." Consequently, though the synclinal folds are some hundreds of feet east and west of the shafts, with the trend eastward, one gets nearer and the other farther away as depth is reached. In the case of the New Chum Railway mine (Fig. 4) the synclinal is 500 feet west of shaft at surface, but at, say, 3200 feet, it will only be about 110 feet west, and when the shaft is sunk still deeper will be intersected by it.

In the same diagram I have shown the position of a saddle reef above the 2029-foot crosscut. This reef was highly auriferous, and it will be an interesting piece of work to trace downward the west leg of this formation until it reaches the channel of the synclinal, which should, approximately, be found by extending a crosscut at 2900 feet. Seeing that the reef above 2029 feet was highly payable, it is at least reasonable to assume that the syuclinal reef will be auriferous also.

Another interesting—and, perhaps, the most conspicuous—example of rock bending and reef formation is that at the Johnson's Reef Extended mine (Fig. 5). In this we have the Pyke and Garden Gully lines of reefs clearly exposed, with the synclinal folds on either side of them. The anticlinal reefs were both payably auriferous and the synclinal reef between also carried gold. Commencing at A, the same "back" or "wall" can be followed continuously to points B and C.

Still another very good section has been secured at the Sea Co.'s mine, and this shows with what regularity the rocks have been deposited (Fig. 6). From this it will be seen that the Paddy's Gully anticlinal is a short fold in comparison with the Garden Gully. By also comparing this diagram with that of the North Johnson's (Fig. 7) it will be seen that the Garden Gully and Paddy's Gully lines of reef have converged, as at the Sea Co. they are 660 feet apart, while at the North Johnsou's they are only 370 feet apart—a distance of 1¼ mile separating the two mines on the strike of the Garden Gully line of reefs.

Many other examples of the synclinal folds might be given, but those selected are typical of the field, and sufficient to illustrate the principle advocated.

EVERY mine where much timber is required in the workings should have a circular saw and a framing machine. By the means of these devices timber can be quickly framed and with sufficient accuracy for all purposes. Sawed wedges are superior to most hand made wedges and can be made from waste pieces of lumber and timber with a minimum of waste. It is economy to buy waste from lumber and planing mills when the same can be had at reasonable prices, for use in blocking in the mine and for making wedges, etc. If shaft timbers are bought as close as possible to the actual dimensions required in the shaft, a liberal allowance must be made for blocking. In a three-compartment shaft the blocking required is often equal to nearly the length of half a wall plate.

THERE are said to be deposits of lead-silver ore in the limestones in the Grand canyon of the Colorado river in Arizona, but owing to the expense of transportation and the difficulties of working these mines the development is not extensive. On the top of the plateau, about 50 miles north of Williams, copper ores occur strewn about on the surface, but it is not known that these deposits are more than superficial.

A STEAM ENGINE of 15 H. P. is large enough to run an air compressor operating a 3¼-inch rock drill, and will also supply air to the forges. A 25 H. P. engine will drive a 2-drill compressor, and a 60 H. P. engine should run a 6-drill compressor. In larger compressors about 8 to 10 H. P. are figured for each 3¼-inch drill.

Gaseous Fuels for Power and Heating.

NUMBER II.

Written for the MINING AND SCIENTIFIC PRESS by H. SHERWOOD, C. E.

To obtain the cost of power by the use of the fuels obtainable on the Pacific slope, notice first what has been outlined: that the poor water gas is chiefly got from coke or anthracite in England. Concerning this, it may be remarked as undesirable here. Lencanchez, in France, uses a low class of bituminous coal for gas and shows a considerable increase of hydrogen thereby. Further remark that, except ash and moisture be increased, the class of coal or lignite employed is equally valuable with any other for water gas. Therefore, the bituminous coal of the Pacific coast will produce as much and as valuable water gas as the best anthracite. We may, therefore, accept the data of production and use of poor water gas from coke, etc., as reliable for water gas which may be produced from bituminous coal. The action is through heating the fuel (carbon) in the generator by air to incandescence, after which the air is drawn in continuously by a jet of superheated steam, or steam under pressure. The gases produced are in composition $25CO\ 18H\ 49N\ 6CO_2$, with a production of about 62 cubic feet per pound of carbon consumed, which gives over 135,000 cubic feet of poor water gas per long ton of fuel. This gas is used in the majority of the Otto engines in England, of which the British patents were bought by the large engineering firm of Crossleys of Manchester, Eng., who made severe and exhaustive tests of the cost of running them by this gas. It was found that 18 I. H. P. engines took 82 cubic feet per indicated horse power per hour—coal gas requiring about 20 cubic feet for the same power and time. The decision came to was that the gas was not desirable for engines of less than 20 H. P., some irregularity in explosion being found; but the gas is admirably adapted to engines of larger size. It was found that in inverse proportion as the diameter of the engine cylinder increased the consumption of gas per horse power relatively decreased. Thus, an engine of 173 I. H. P. showed a consumption of 60% of the proportionate gas required by the smaller engine mentioned, while the 18 H. P. engine took gas equal to 1.2 pound of the fuel per horse power per hour, the larger size took but equal to 0.76 pound of the fuel per hour. An engine of 100 I. H. P. would therefore consume gas about equal to 1 pound of carbon consumed: viz., 62 cubic feet (which agrees very closely with the data given in the improved gas generators of pure water gas, to be referred to later on). Taking $7 a ton of 2000 pounds as the value of the fuel, the cost of thus running an engine of 100 H. P. is under 9 cents per horse power per twenty-four hours, while with the larger-sized cylinder tested the gas consumed is but 47 cubic feet per horse power per hour at a cost of 6½ cents per horse power per twenty-four hours. It must be noted that these are the largest engineers in that large manufacturing city, and run their own shop, requiring several hundreds horse power, entirely with these engines and with this gas. In the Lencanchez generators is employed the lowest and cheapest class of coal. No data have been published, but its use has been extended to about all the Simplex engines, which are very widely employed.

When pure water gas is made the carbon is heated to incandescence by air blast through combustion of part of itself, and the products of combustion removed from the generator, after which steam under pressure is blown through the heated carbon until it becomes cooled by the steam too low to dissociate its elements, when the operation is ceased and another period of heating to incandescence is begun. As a temperature of from 500° to 1200° C. is needed for dissociation, the cooling action of the steam at not over 160° C. is rapid. The interval of blowing to incandescence was therefore long, while the forming of water gas was short. The amount of "producer gas" formed was therefore considerable, and used by the gas works of cities to heat their coal gas retorts, while the water gas passed to carbureters before mixing with coal gas. By the improved generators, the time of heating the carbon is reduced to one-fifth of the total time, while the time of producing the pure water gas is increased to four-fifths of the total time. The work is thoroughly successful, and has been for some time past continuously in use. The data obtained on the results of this process are vouched for by some of the highest scientific men in Europe. Special tests made continuously in their presence showed that 1 pound of coke produces 34 cubic feet of pure water gas. To this consumption must be added, if the gas be required for power in gas engines, the consumption during the heating of the carbon which cannot be passed into water gas. The quantity of such gas required in the cylinder of a gas engine per hour to give out 1 I. H. P. is from 30 to 35 cubic feet. Therefore a total fuel of 1.07 pound of coke per hour ensures 1 H. P. in the gas engine. This, at $7 per ton, equals 9 cents per indicated horse power per twenty-four hours in an engine of 80 H. P. This grade of gas is adapted to every size of cylinder, but with the same economy for large cylinders, which is inherent in every gas engine. In employing this gas the volume of air required for explosion is double that of poor gas. The

data given prove the correctness of both, and show both to be fully reliable. The analysis of this pure water gas is about 31CO 51H CH $5CO_2$ 4N, making 83% of explosive gases with 9% inert gases, balance being moisture.

Notice now the fuels convenient to use on the Pacific coast. The crude petroleum of central California has mostly an asphaltic base. As this is less advantageous for lighting oils than with a paraffine base, California oil may long remain a moderately costly fuel. For water gas making its base makes little difference. The asphaltic residue has its carbon changed by heat and steam as any other carbon is. The residue of oil distilling is also completely converted by air and superheated steam. The generators, made for converting these into water gases, employ coal or wood as the solid incandescent carbon, while the heaviest portion of the crude oil also carbonizes and spares the use of much specially employed. The special generator made for petroleum is on the principle of pure water gas from coke with superheaters for the petroleum and steam injected, which are 1¾ pound of crude oil to 1 of water or steam. It may be employed to produce either grade of gas. No complete data have been published of its production or its use, as in many other fuels, but knowing the composition of petroleum, these may be assumed very accurately and verified by its use in burning with steam. Its conversiou into fixed gases is very perfect, but requiring a higher heat in reassociation than most other fuels owiug to the extreme volatility of the highest portions. By calculation, there would be produced from 1 ton crude petroleum 58,000 cubic feet of water gas, of which 65% is H, 33% CO, with a little inert gas. Such a gas needs for its complete explosion uot under eight volumes of air to one volume of gas, of which, not over 20 feet are required to give out 1 H. P. in oue hour. The extreme calorific quality suggests that, for power alone, it is more useful as poor gas containing its own volume of nitrogeu, consuming double the quantity in the engiue cylinder, and using half the cold air to explode. The cost per horse power per tweuty-four hours, taking $1.67 per barrel for petroleum delivered far from railway, would reach 9 cents (using pure water gas with engines under 80 H. P., but most probably not over 7½ cents per horse per twenty-four hours using it as poor gas in engines of 100 H. P. and upwards). Iu San Francisco, Cal., the cost of horse power per twenty-four hours would not exceed 5¼ cents, used as poor gas in large engines.

At the present time most gas engines are run by sprayed oils distilled from petroleum. Taking gasoline at 11 cents per gallon and distillate at 8 ceuts, it is not an economical source of large powers. Petroleum with paraffine base is purchasable at $1.25 per barrel—making 3 cents a gallon, giving off on heating four-fifths of its weight in clean vapor. An engine is specially prepared for using this—the Economic gas engine. Tests of the cost of power by this use of crude petroleum are claimed to have shown a cost per horse power per twenty-four hours to be about 10 cents after allowing for the residue—certainly a convenient, cheap supply for small powers. The same power would probably cost by gasoline 28 cents; by distillate, 21 cents, and by city gas, 32 cents. Larger powers would find a reduction. In mills away from railroad, for which an average cost of $1.65 per barrel of crude petroleum is assumed, the cost of power in the crude petroleum gas engiue would be about 13 ceuts per horse power per twenty-four hours. But in these engines it must be borue in mind that exceept the petroleum have paraffine base there must be great liability of furring an engine cylinder, through imperfect purity of the gas from coudensible asphalts.

(TO BE CONTINUED.)

AT Tinton, a new mining camp in western Lawrence couuty, South Dakota, a concentrating mill is approaching completion. It is being built to treat the tiu ores of that district. This sectiou of the Black Hills, known as the Bear Gulch region, consists of mica schists and slates of Algonkian time. These ancient rocks are intruded by dikes, large and small, of a very coarsely crystallized granite, known as pegmatite. In these dikes occur tin, rare iron ores, phosphates, tourmalines and other minerals, besides the normal constituents of the granite—feldspar, quartz and mica. Some of the veins also coutain gold, associated with the tin. The tin-bearing rocks are not unlike those of the Harney Peak region, 65 miles to the southeastward, where tinstone also occurs. Several attempts have been made in the past to concentrate and reduce the tin orcs of the Black Hills, but these efforts have thus far proved commercially unprofitable. There is much interest in the outcome of this renewed attempt to treat the Black Hills tiu ores. The plant at Tinton is the first one built in that section of the Hills, all of the others being in the Harney Peak region.

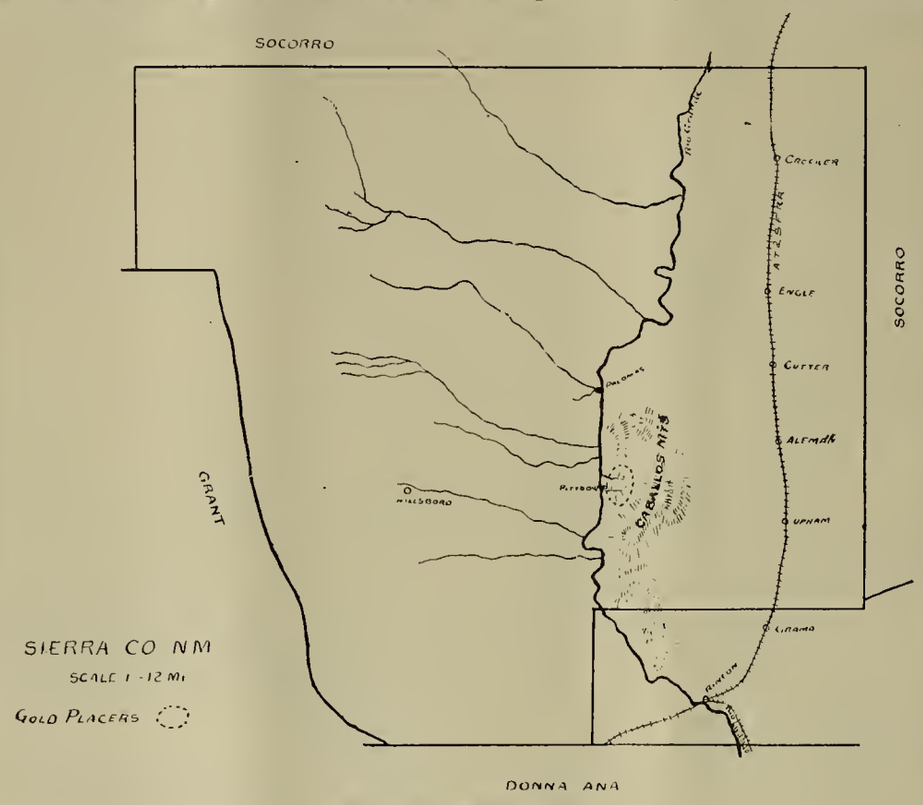
THE miners of British Columbia are petitioning the Provincial Government to remove the duty from crude petroleum in order that the cost of fuel oil and oil for concentration may be reduced to a point which will render its use possible iu the mining regions of that province. The duty at present is 5 cents per gallon.

Notes on New Goldfields, Sierra County, New Mexico.

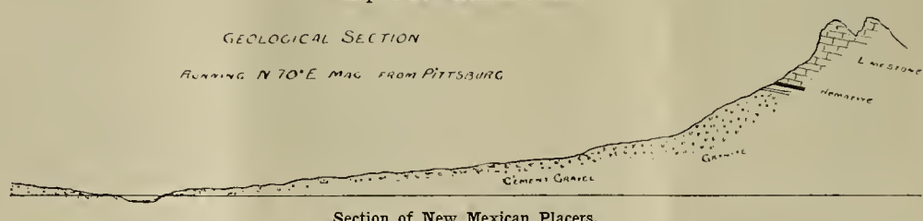
Written for the MINING AND SCIENTIFIC PRESS by E. P. SMITH.

Gold has been known for a number of years to exist in the recent gravels on the west side of the Rio Grande, in Sierra county, in the neighborhood of Hillsboro—not, however, in sufficieut quantities to prove profitable. The discovery of the metal during the early part of December on the east side of the river has awakened unusual interest in the district. Exaggerated reports as to the extent have been spread about, but that certain rich portions of the gravel could be readily panned by blowiug with the mouth on the haud or pau, and that considerable gold was so taken out, are undoubted facts.

The field lies on the east side of the river, the chief strike being at a point about 10 miles south of Palomas. A town, composed of twenty-five or thirty (December 18) tents, and known as Pittsburg, lies close to the river on an eighty-acre tract of patented ground owned by the Grayson Cattle Co. It contains a uumber of stores, saloons and a hotel, and forms a base of supplies for the numerous smaller camps scattered betwcen the river and the mountains.



Map of New Mexican Placers.



Section of New Mexican Placers.

These mountains, the westeru chain of the Cabollas range, are about 4 miles distant in a straight line from the river, and run, in general, parallel to it.

The summit is about 6000 feet above sea level (taken by aneroid), or about 3000 feet above the river. From the summit there is an abrupt drop of 1000 feet or more, and then a gradual descent to the river.

The slope is made up of a deposit of cemented gravel, whose thickness is exposed in some places as much as 200 feet by arroyos. The main arroyos run directly towards the mountains, east and west, while the tributaries run to the quarter points.

In the bottom of this system of dry streams has been laid down a layer of loose sand and boulders, whose thickness rarely exceeds 4 feet, and in the smaller gulches is but a few inches.

In the bottom of this, usually on the irregular surface of the cement gravel, is found the gold.

The main arroyos are from 50 to 150 feet wide, and in them this later gravel is thickest, while the small tributaries are about 5 to 10 feet wide, and in these most of the work has been done.

The boulders are picked out, the top layer of sand scraped away and the bottom part carefully scraped or brushed up from the hard cement. This is put in pans and blown upon until the particles of gold can be picked out.

Most of the particles are coarse, as would be supposed from this crude method of treating. The size of a wheat kernel is, perhaps, the most common, while they run as high as two pennyweights. The larger operators are now packing the rich sand in sacks on burros to the river and cradling it. Also two small hand-power jigs have been used, with only fair results, however. Most of the operators are Mexicans and the greater part of them seem content with the blowing method.

The accompanyiug section, taken along a general line running north 70° east magnetic, will show the geological structure of the country lying to the east of where the greater part of the gold is found.

The granite, which extends from where the cement gravel ends part way up the mountain, a horizontal distance of ¾ mile, is of a pinkish color, containing segregatious—rather than veins—of pegmatite. It is also crossed by dikes of diabase 2 or 3 feet wide, running east and west.

Resting on the granite is a serics of sedimentaries, startiug with a thin layer of hard, white quartzite, then about 8 feet of impure limestone, ou which rests about 8 feet of an oolitic hematite. From this to the summit is a series of limestones and shales, full of siliceous concretions and showing some fossils, crinoids and spirifers. The whole series dip 20° to the uorth-east.

Through the upper limestones passes a heavy fault, judging from the brecciated area, and in the same strata are numerous small quartz veins—seldom over 1 foot in width.

These same formations—the granite overlaid by a similar if not identical series of sedimentaries—can be seen to continue up the river ou the east side as far as Palomas. Yet the area where the gold in any quantity has been found may be confined to a section 2 miles square.

It would seem that the origin of the gold must be from either the granite or the small quartz ledges in the upper limestones, and, not finding values farther up the river, would lead one to expect values in the above-mentioned ledges.

The large mass of cemented gravel has not yet beeu proved valuable, while the small amount of loose gravel at considerable distance from the river will hardly prove much of an inducement to install a large pumping plant.

The Trujillo and Silva groups take in about all of the really proven ground, while for 15 miles along the river all the ground has been located to the summit of the Caballos range.

Slimes Treatment.

Written for the MINING AND SCIENTIFIC PRESS by D. G. APLIN.

The following is written in the hope that it may help some one who has a small body of slimes to work, and who does not wish to incur great expense. It is well enough to be told by various authors on cyaniding that "slimes are generally worked with centrifugal pumps and filter presses," but as far as actual practice goes such a statement is of little benefit. The writer does not contend that our treatment of slimes was good practice in general. In fact we are now doing it much better, by taking the slimes directly from the mill. However, under adverse conditions, with very little outlay, we cyanided about 2500 tons, at reasonable cost, and obtained good extraction.

The circumstances were these: The San Francisco mine had produced about 30,000 tons of tailings. These were run into a reservoir without classification. The layers of sand were taken out and cyanided, and the layers of slimes also taken out in part, and dumped down the side of a canyon. As we cleaned out the dam, we continued this process of separation. I found that we obtained nothing from the slimes when mixed with sand, and so cut out all possible.

When the sand was finished we had three piles of slimes containing about 10% of sand, and perhaps 5% of rocks, the latter varying in weight from a few ounces to fifty pounds. The larger rocks were put in to support two well boxes in the dam, and the small ones came from sides of the canyon. We had insufficient ground on which to spread these slimes, and so were bothered in drying them, but managed to dry almost as fast as the plant required.

Our equipment consisted of three 65-ton wooden tanks, and twenty-four 10-ton iron tanks, for leaching; two 40-ton wooden tanks for solution and sump, and a 20-ton iron tank. We used this 20-ton tank for our agitator. It was 16x8 feet on top, 6 feet deep, and ran down on the bottom like a letter "U."

We fitted up a discarded 2-inch centrifugal pump with new shaft and vane, and connected it to draw from the forward end of this agitator, and discharge into the other end. This discharge—a 2½-inch pipe—also passed ou over the settling tanks, and the openings were stopped with wooden plugs. The suction was 3-inch, with discharge opening between tank and pump. There was also an inlet for water, which came in under about 80-foot head.

Our crushing rolls were placed on stringers over the pump suction, at the forward end of the tank, and a small slimes bin was built over the back end. We made the rolls for crushing out of discarded boss heads. We plugged the key-ways in these bosses, set short pieces of shafting in the ends, and filled in with molten scrap brass. The rolls, when completed, weighed about 300 pounds each, and were 21 inches long by 9 in diameter. Bearings for one roll were fixed to slide, and behind these bearings were placed pop-valve springs to hold the roll up to its place. One roll ran about ninety revolutions per minute, and the other about one-third faster.

Our power was obtained from a 4 H. P. gasoline engine. It was not strong enough to do the pumping back and putting on of solution while we were running the rolls and agitator, so that had to be done at night.

Directly under the rolls we placed a jig screen, which projected over the edge of the tank, and screened out rocks and sticks. Its meshes were about ¾ inch square, and any slimes too moist to pulverize went out with the rocks. In this way we lost about thirty tons of slimes, but the screen was an absolute necessity.

Two men supplied material, and two ran the machinery and fed the rolls. In the beginning of our operations, we found that the 40-ton sump and 10-ton gold tank were insufficient to handle the large bulk of solution, and so we coupled two 10-ton tanks on the sump, and five 10-ton tanks on the gold tank. The seventeen iron tanks remaining were moved down on a level with the big wooden tanks, and all used for settling. For carrying off solution, a pipe was introduced through the bottom of each settling tank, with swinging arm which could be raised or lowered. An opening was made in the bottom of each tank, and closed from the inside with a long-handled wooden plug.

In operation the plant worked as follows: Seven tons of solution, made up to three and one-half pounds of cyanide to the ton, was run into the agitator, and the pump started. With the solution in motion, dry slimes were fed through the rolls as fast as a man could shovel, until five tons had been put in. If the pump showed signs of clogging up, the feeding was stopped for a few minutes, or a little water was run into the pump suction. Beginning at 7 o'clock, a charge would be put in a little before 9. At once the sludge would be turned from the agitator into a settling tank. When it was quite low in the agitator, solution was turned into the back end, and three more tons of solution used to wash out the agitator. At the end of thirty minutes the sludge and wash had been pumped into the settling tank, and the agitator was ready for another charge. Four men could put through twenty tons per day, during which time twelve gallons of distillate were used for power.

The dissolving solution was drawn off at the end of twenty-four hours, and a second solution, from the sump, pumped on through a fire hose. This pumping on was sufficient to agitate the sludge quite thoroughly. A third solution was then put on, and following this a final wash water. It is seen that this method of washing and dissolving took five tons of solution to every ton of dry slimes treated. The large bulk of the solution handled necessitated large pipes. I tried lime to help settle the sludge, but found that in this case it did little good. The time required to put through a tank was as follows: One day to settle each of the first three solutions, and two days to settle the wash water. Tanks could be emptied quickly and filled the same day, making five days to finish each. The capacity of each tank to work slimes was equal to about one-third of its capacity measured in sand.

We put steel plates, ¼ inch thick, on the inside of the pump, and had to renew them for each 600 tons treated. The pump shaft and vane had to be renewed at the same time, so that in working 2500 tons, we wore out four shafts, vanes, and sets of plates. Of course, the amount of sand was considerable, and every evening we had to clean out the agitator. We extracted 50% of the value from this sand.

The solutions, especially the last one, were rarely clear, as they passed through the zinc boxes, but the slight cloudiness did not interfere with precipitation. It did, however, result in muddy slimes, and necessitated a larger quantity of fluxes in the cleanup. We mixed each wash water with a dissolving solution before passing them through the zinc, and thus secured almost perfect precipitation. I often obtained only a trace of gold from five assay tons of sump solution.

Cyanide consumption was high. This was partly due to copper in the slimes, and partly to loss of solution in the sludge. Our work resulted in a consumption of almost two pounds of cyanide to the ton of dry slimes treated. The extraction averaged 82%.

Since cost of labor and supplies depend so largely on local conditions, I will not give the cost per ton here, but will give below equipment, number of men and approximate supplies necessary to handle twenty tons per day, as we worked them:

One 40-ton standardizing tank.
One 80-ton sump tank.
One 60-ton gold solution tank.
One 15-ton agitator.
Settling capacity of about 75,000 gallons.
Thirty-five cubic feet of zinc.
Five men nine and one-half hours per day.
One 2-inch centrifugal pump; repairs $10 per month.
One 2-inch rotary pump.
Fifty feet of 2-inch fire hose.
Four horse power sixteen hours per day.
Crushing rolls.

Of course, the necessary small tools and incidentals, such as are in ordinary use around a cyanide plant, need not be mentioned.

At present we are running the tailings from the mill directly into a hydraulic separator. From this the sand runs into the tanks, where it is cyanided with excellent results. Slimes run from the separator into the old dam, and from this are drawn out into tanks and cyanided by decantation, as described above. After two months' trial of this method of handling tailings, we find it vastly more economical than any way of working up dry slimes.

Mexico Quicksilver Mines.

The most important quicksilver mines of Mexico are those of the group named Huitzuco situated about 20 miles from Iguala, a station on the Cuernevaca railroad, says the Miner and Manufacturer. The mines in question cover an area of 568 pertenencias of 100 by 100 meters. Of these mines thirteen are in exploitation, three of which are producing quicksilver of an excellent quality. The deposit is very extensive and the veins well defined. The principal shaft is down 800 feet and clearly demonstrates the depth of the mineral deposit. Excellent metal has been taken out at different levels for a distance of 150 feet, showing the width of the veins, which are composed almost entirely of ore. There are many properties that the ores are richer than those of Huitzuco, yet there are none that, taken as a whole, are so valuable. The value of this property consists in the immense deposits. There are many thousand tons of the ore in view at the present time. The reduction works consists of six furnaces 50 feet high, constructed after the model of those used in the California quicksilver mines with all the necessary condensers and appurtenances, all of the most modern type. From the mines to the reduction works is a distance of 6 miles. A tramway transports the ore from the mines to the works.

Copper Ores and Their Physical Appearance.

Written for the MINING AND SCIENTIFIC PRESS.

No ores are more interesting and attractive than the various ores of copper. The prospector is usually fairly well informed as to the appearance of some copper ores. He knows that at the surface they are generally green or blue, and accordingly believes all rocks or ores having a bright green color are copper ores, and that bright blue ores are also copper ores. While this is mostly the case, there are important exceptions to the rule. The bright green scales so commonly seen associated with quartz and dolomite in the gold belt of California is mariposite, a variety of mica, and contains no trace of copper, the color being due to chromium oxide. There are also certain iron silicates—such as glauconite—which are green and contain no copper. Some chrome ores are bright green, and gouthite and garnierite, two important nickel ores, are also green, while containing no copper. It should not be thought, however, that because a green ore contains no copper it has no value, for, with the exception of mariposite and glauconite, all of the above-mentioned ores are valuable when occurring in sufficient quantity.

The beautiful blue copper carbonate, azurite, bears a close resemblance to linarite. A basic sulphate of lead and copper, vivianite, is a bright blue ore resembling azurite, but contains no copper, being a hydrous phosphate of iron.

The most common ore of copper which the prospector sees in his surface examinations is undoubtedly the green carbonate, malachite. Less frequently he sees azurite, the blue carbonate, and still more seldom cuprite, the red oxide. The black oxide is more common, but may be confused with other more common minerals, particularly with black manganese oxide.

Malachite is bright green in color. It occurs massive, in radiated, star-like crystal groups, and incrusting. It is deceiving, in that a small percentage of this mineral will give a decided green color to the rocks containing it. The prospector should be guided to some extent by the weight of hand specimens, for if the ore is high grade in copper it will be much heavier than a rock of similar size that is merely stained with the carbonate. The fracture of malachite is uneven. It is brittle, with hardness of 3.5 to 4; gravity about 4. It occurs earthy and dull, crystallized, sometimes in transparent crystals, often in silky fibers. The streak made by scratching with a knife is green, but lighter in color than the mass of the mineral. When heated before the blowpipe, colors the flame green. It is soluble in acids. A solution of malachite in nitric acid colors the liquid green. An addition of ammonia in excess turns this color to dark blue. Azurite is the blue carbonate and resembles malachite in its physical properties—that is, is earthy or crystallized, hardness 3.5 to 4, gravity 3.8, streak blue, but lighter than the mass; colors blowpipe flame blue; dissolves in acids, etc.

Another ore of common occurrence is chrysocholla, a silicate of copper, of a green or bluish green color. It has a luster varying between earthy and vitreous. Its hardness varies considerably—from 2 to 4—but it is much lighter than malachite or azurite, having a gravity of but 2 to 2.2. This ore often resembles turquoise. When impure it is sometimes brown or black. When pure it contains about 45% copper oxide. It is found associated with other copper ores, particularly in surface portion of deposits. This ore also colors the blowpipe flame green, but, unlike the blue and green carbonates, is infusible without the aid of fluxes. It is decomposed by acids.

There are numerous rare copper ores of limited occurrence which have a bluish or green color, but it is unnecessary to mention them in connection with the more important ores of copper.

Cuprite is an ore not infrequently seen in the croppings of copper veins. It is commonly called red copper ore and resembles bright red iron oxide (hematite). It occurs earthy and also crystallized. In the latter condition it often assumes octahedral shapes. Its color is red of various shades from light to dark. It is the richest copper ore, containing when free from impurities 88.8% metallic copper. It is softer than hematite, but harder than cinnabar or proustite (red silver ore), for which latter it is often mistaken. Many mineral cabinets contain handsome groups of crystals of cuprite which are erroneously labeled "ruby silver." Cuprite also colors the blowpipe flame emerald green, and on charcoal fuses to a metallic bead of copper. These characteristics serve to distinguish it from hematite and other minerals of red color.

The black oxide of copper occurs with greater or less frequency associated with other ores of copper, and is particularly noticeable with copper ores occurring in slates and schists, as at Ducktown, Tennessee, in Pennington county, South Dakota, at Keweenaw Point, Michigan, and in North Carolina and Virginia. It is often accompanied by oxides of iron and manganese. It can be distinguished from other black earthy minerals by its reactions for copper before the blowpipe and in treatment by acids.

The black oxide of copper contains a high percentage of the metal.

The above are the principal copper minerals with which the prospector has to deal when exploring the surface for mineral veins, and all of them are directly or indirectly the result of the oxidation of chalcopyrite, the yellow copper sulphide. In the superficial portion of ore bodies containing a large amount of sulphide of irou, or iron and copper sulphides, the sulphides often oxidize where above the drainage level and leave only a gossan of iron oxide. Although pyrite and marcasite (iron sulphides) are more subject to oxidation than tbe copper-iron sulphide (chalcopyrite) yet in many instances the copper also has disappeared, leaving no trace of its previous existence in the gossan, which consists of red or brown iron oxide, with more or less silica, lime, etc., as gangue. In a district where veins occur the prospector should investigate all such iron gossan carefully, for beneath may lie a rich deposit of copper ore. When a deposit originally containing iron and copper sulphides has become oxidized, with the iron gossan only remaining, it is usually found on sinking into the deposit that the copper has been leached out, probably by the sulphuric acid produced by the oxidation of the pyrite, and that it has been carried downward by surface waters, to be precipitated at or near drainage level upon the iron oxide there present, producing a zone of rich copper carbonates and oxides. Below this, again, is sometimes found an enriched sulphide zone in which occur bornite, chalcocite (copper glance) and other sulphides rich in copper.

Chalcopyrite, the principal sulphide ore of copper, though not the richest, occurs at the surface in some veins. It resembles pyrite somewhat, but is more yellow, with (in some specimens) a faint greenish tinge. It is softer than pyrite and may be scratched readily with a knife. It has a metallic greenish black streak. This ore is soluble in nitric acid, coloring the solution green, which turns blue upon additiou of ammonia. Iron sulphide is often tarnished yellowish and then resembles chalcopyrite. but the superior hardness of pyrite will serve to distinguish it from tbe copper sulphide.

Bornite is a sulphide of iron and copper, with varying proportions of these metals. It usually contains upward of 30% copper, and sometimes considerably more. It presents a bright, iridescent appearance, showing bright tints of green, purple, blue, etc. In the true bornite these colors penetrate throughout the mineral, but some specimens of chalcopyrite are colored in this manner by a thin film of color whicb is due to semi-oxidation of the sulphide. This is commonly called by miners "peacock copper." But this is a misnomer, for it is uot bornite. Copper glance and the still more rare arsenical aud autimonial compounds of copper are of too restricted occurrence to make it necessary to describe them here.

Discovery and Development of the Homestake Mine.

Written for the MINING AND SCIENTIFIC PRESS.

Gold was known to exist in the Black Hills of South Dakota several years before the stampede to that region in 1875–76; but the knowledge was of an indefinite nature, and until venturesome prospectors entered the Hills in the fall and early winter of 1875 nothing was actually known of the country or its resources. The Black Hills rise like an island from the sea in the great plains which surround them. The Hills, together with the Bear Lodge mouutains, which are on the northwest side, though the latter is a separate uplift, form essentially one area of elevation and are detached from the Rocky mountain system, lying at least 300 miles easterly from the main rauges in Wyoming. The Hills are covered with a forest of pine timber, which from a distance gives them a somber aspect and suggested the name Black Hills to the early explorers. The first parties of gold hunters found placer gold on French creek, in the southern hills, in Custer county, a few miles from Custer City. Gold was also found on Spring creek, Battle creek, Castle creek and Rapid creek, and in many small, dry gulches; but, although individuals occasionally did well in these placer workings, the majority only met with moderate success. Several parties pushed on into the northern hills, and one of these, known as the Gordon party, while searching for lost horses, came down a gulch from the westward into what is now known as Deadwood gulch, and found gold on a bar of that stream, about a mile and a half above the site of Deadwood City. The district was called "Lost district." The "strike" proved a rich one and claims were quickly taken. The news spread, and in an incredibly short time Deadwood gulch was staked for miles above and below discovery. Claim No. 1 below was owued by Wheeler Bros. It occupied a flat about 200 feet wide in the gulch. The bedrock was nowhere over 5 feet deep on the claim (300 feet on the gulch reaching from "rim to rim"—that is, 30 feet above the creek on tbe hillside—) and it probably averaged less than 4 feet. From this claim in the summer of 1876 over $100,000 was taken, and the ground was worked over three times afterward with fair results. Other claims did almost as well; but, as usual, some were comparatively worthless.

All the tributaries of Deadwood gulch, and, in fact, the entire drainage system in the neighborhood of Deadwood, was located, and the development of the placer mines soou indicated that tbere was some central point from whicb the gold came. Bobtail and Blacktail gulches, tributaries of Deadwood gulch, were very rich, and, being shallow, were worked out the first two seasons. At the site of Deadwood another good-sized stream joins Deadwood gulch. This is known as Whitewood. About 2½ miles above Deadwood City a narrow gulch enters Whitewood. It is called Gold Run. This was one of the richest of the numerous gulches found. Other tributaries of Whitewood were located and tested, but proved of inferior value. The pay extended up Whitewood to Gold Run, but was poor above the mouth of that stream, indicating that the source of the gold lay somewhere on Gold Run. Bobtail headed only a short distance from the west branches of Gold Run, and pay got poor on Deadwood near the mouth of Poorman gulch. The results of placer mining indicated that the source of most of the placer gold lay in the region drained by the several streams named. Long before this fact was demonstrated, however, prospectors were searching for quartz which would prove to be the source of gold found in the placers. Among the first deposits found, unlike the gulch diggings, were outcrops of hard ferruginous conglomerate, which in numerous places was found to be rich in gold. The hills about Central City were capped with beds of this character and stamp mills were soon erected to crush this gold-bearing material, which was so easily mined, lying in some instances on top of the ground, and in all cases having a slight dip to the northeastward. In time the fact was recognized that these detacbed deposits had at one time been a continuous sheet, which had been intersected and divided into numerous separate areas by the cutting out of the gulches.

Among the first to seek for quartz veins were the Manuel Bros., and these men found on the west side of the broad open valley near the head of Gold Run an outcrop of deep red quartz rock, which contained a prospect of gold. With possible visions of a life in a home in a region far removed from the wilderness in which they found themselves, they called the first claim "Homestake." The vein proved to be wide—varying from 50 or 60 feet to more than 100 feet in places. Although the Manuel mine was recognized as gold-bearing, it was so low grade, as compared with mines with which they and other miners were familiar elsewbere, that at first little confidence was placed in it. However, other claims were staked all over the district, many of them showing gold. Tunnels were driven into the hill on these great masses of red quartz, and it was seen that there were a number of large veins lying nearly parallel, all containing more or less gold, but none of them rich. A specimen of free gold was uncommon. Mills were built and the quartz ore from the Homestake and surrounding claims and also that from the conglomerate beds were crushed in these mills, most of them running on custom ore. These ores were found to crush rapidly and to yield a high percentage of their gold contents to amalgamation—were, in fact, free-milling. This was the first encouragement the owners of the large low-grade deposits had had, for most mining men who had visited and inspected the veins declared them either too low grade to pay in that region—300 miles from the nearest railroad—or, at least, to form a very dangerous risk for investment of the necessary large capital.

The first mill on the Homestake mine contained thirty-five stamps, weighing about 650 pounds each. Ore was delivered by wagons and dumped on a plank floor back of the line of mortars and all feeding was done by hand, the large rocks being spawled by men with heavy hammers. Still, notwithstanding tbese primitive and expensive methods, the low-grade ore paid expenses, and in some cases it paid handsomely. Among other uoted mines on the great mineral zone were the Highland, which joins the Homestake, the Golden-Terra, the Deadwood, both on Bobtail gulch, the Caledonia, in the same valley, and the Father de Smet, on Deadwood gulch. Each of tbese mines was owned and operated by a separate company in the early days of their history.

The first large mill built in the Black Hills was tbe Homestake mill, originally containing eighty stamps. This was built in the summer of 1878 and the following year the Golden Star of 120 stamps (now 200), and later the Highland mill of 120 stamps (now the Amicus with 140 stamps and 100 to be added). The Father De Smet mill was built in 1879 and contained 100 stamps. This mill is now known as the Mineral Point. The Deadwood and Golden Terra mines each had sixty stamps originally. In later years the mills were united, and it now contains 160 stamps, and is known as the Pocahontas mill. The Caledonia mine was originally worked with twenty stamps, but a new mill was built in 1879–80 of sixty stamps. This mill, now the Monroe, now contains 100 stamps. These facts show how the work of extension on the Homestake has gone on with the development of the property.

The Homestake was the first very large low-grade gold mine to be profitably operated, and has "set the pace," as it were, for low-grade mines everywhere. There are more favorable economic conditions in some other regious, and mining and milling can be carried on more cheaply under such more fortunate conditions than at the Homestake, but the mining and milling methods of that concern have been reduced to a science, and these methods may in many instances be followed with satisfactory results elsewhere.

Cobalt-Nickel Arsenides and Silver in Ontario.*

Written by WILLET G. MILLER, Provincial Geologist, Toronto.

Recently the discovery of cobalt-nickel-arsenic and silver ores in the northern part of the Province of Ontario has been made public. Little importance appears to have been attached to the deposits by those wbo first saw them, it beiug thought that they carried but a small amount of copper, the niccolite being mistaken for this metal. T. W. Gibson, the Director of the Bureau of Mines, when on a recent visit to the district, received specimens of the minerals, and recognized that they represented valuable ore. Tbe writer was, accordingly, instructed to make as thorough an examination of the deposits and surrounding area as could be made at this season of the year, snow having already begun to fall in the district.

The deposits were discovered during the building of the Temiscaming & Northern Ontario, the government railway, which is now under construction from North Bay Junction, on the Canadian Pacific, to the head of Lake Temiscaming. The roadbed of this new railway ruus almost over the top of the first of the deposits discovered. The ore bodies lie 5 miles south of Haileybury, one of the two villages on the Ontario side of the northern part of Lake Temiscaming. Haileybury, following the railway, lies about 106 miles north of North Bay station, which is, by the Grand Trunk Railway, 227 miles north of the City of Toronto.

As the deposits were discovered recently, and the surface is covered with snow, little prospecting has been done in the surrounding area. The discoveries were made by men employed on the railway, and not by prospectors; hence the work has not been done as systematically as it might have been.

When I visited the locality four veins had been located in the vicinity of a small body of water known as Long lake.

Each of the four veins visited was found to carry cobalt. Nickel also appears to be present in all of them; but as the weathering of the cobalt compounds masks, at times, the nickel colors, this latter metal was not definitely recognized in two of the deposits, although it doubtless occurs wherever the cobalt is found. Three of the veins are rich in native silver.

Little work has been done on any of the veins, and as the surface is covered with moss and soil it is impossible to state what is their horizontal extent. All of the veins cut through one or both of the formations known in the district as Huronian slate and breccia-conglomerate. The latter rock is considered to be composed of volcanic ejectamenta—grains and fragments of various kinds which have become consolidated.

The slate and conglomerate have a slight dip, and the veins referred to cut them almost vertically. The strike of veins Nos. 1 and 3 is approximately northwest and southeast. Diabase and grabbo invade these fragmental rocks in some parts of the district, and seem to underlie most of the area.

Vein No. 1 has been uncovered at three points, which are within a few yards of one another. As the surface of the rock is low here, and little of it is exposed, it is difficult to tell much about the form of the deposit. Medium grained, dark-colored conglomerate is found on one wall. At the widest opening the deposit has a width of over 6 feet, but the vein matter is more or less mixed with rock. The ore consists of niccolite (the arsenide of nickel) and smaltite (the diarsenide of cobalt), together with much native silver. Niccolite contains, theoretically, 43.9% of nickel and 56.1% of arsenic. Smaltite carries 28.2% of cobalt and 71.8% of arsenic. The ore of nickel now worked in Ontario, the iron sulphide or pyrrhotite of Sudbury, in whicb nickel occurs not as an essential but as an accidental constituent, carries, on the average, less than 5% of the metal. On weathered surfaces the vein matter is coated with the beautiful pink decomposition product, cobalt bloom. The green uickel stain is also seen on some surfaces, but is usually masked by that of the cobalt. This nickel compound is probably the arsenate (annabergite), but nickel silicate may also be present. The scondary mineral, arsenolite, was seen on some specimens. The native silver occurs as films, or leaves and fine threads, or moss-like forms, through the nickel and cobalt minerals especially in the niccolite, as well as in cracks in the rock and in the calcite veinstone. In weathered portions of the ore the silver shows distinctly. One sheet composed chiefly of silver, attached to a rock surface, had a thickness of nearly 0.375 iuch and a diameter of 1 foot. Pro-

*Abstract of Paper in Canadian Mining Review.

fessor Nicol has recognized the antimonial silver, dyserasite, as was suspected in the field, in association with the native silver. He has also proved the presence of chloanthite. It is associated with the niccolite, and also occurs, pretty free from cobalt, in some of the nodular masses in the calcite.

A sample showing native silver was found by A. G. Burrows to possess the following composition: Silver 26.24%, value $5237.60 per ton, cobalt 8.34%, nickel 5.26%, arsenic 13.28%. Another sample, composed essentially of niccolite contained 5.02 ounces of silver to the ton, and nickel 26.64%, cobalt 6.16%, arsenic 45.67%.

As so little work has been done on this ore body it is difficult to determine whether the three openings belong to one vein or whether the ore occurs in a more irregular deposit, although the chief opening appears to be on a vein-like body. The ore is undoubtedly very rich, containing values in nickel, silver and arsenic, and a comparatively small vein could be worked at a profit.

On location No. 2 the ore body is distinctly vein-like in form. The ore here is a mixture of smaltite, and probably some closely related arsenides of cobalt, such as safflorite and niccolite. The only complete analysis which has yet been made of the ore from this locality was that of a sample from this vein. It was found to have the following composition: Cobalt, 16.8%; nickel, 7%; iron, 6.3%; arsenic, 69%; rock matter, 0.9%; total 100. An average sample taken by the writer across the vein at one point gave the following percentages: Cobalt, 16.76%; nickel, 6.24%; arsenic, 66.60%; sulphur, 3.37%. Antimony and silver were found to be absent. This ore body, unlike the other three examined carries no silver in the parts so far uncovered. Three openings have been made on the vein over a length of 300 feet. The massive ore has a width of 14 inches, but vugs in the wall rock, 2 feet feet or more from the vein, are filled with cobalt bloom. The rock of both walls is slate. The walls are well defined and the vein dips almost vertically, the strike being toward the southeast. The vein lies on the hillside and is at a height of about 70 feet above the water level. Although the width of this vein is not great, the character of the ore is such as to make it promising, at the present prices of the metals contained in it.

The ore has a massive appearance and a dark gray color, where not coated with cobalt bloom. When examined in hand specimens, especially if a polished surface be examined with a magnifying glass, it is seen to be a mixture of a gray mineral, which is chiefly smaltite, and the reddish mineral, niccolite. Smaltite and the corresponding arsenide of nickel, chloanthite, are claimed by most authors to pass into one another by the substitution of cobalt for nickel, and vice versa. Niccolite, in the analyses quoted by Dana and others, carries only a small percentage of cobalt and iron, while smaltite and the other diarsenides of cobalt frequently contain much iron and nickel.

Minute, brilliant, silver-white or tin-white crystals occur sparingly, embedded in the wall rock and in the ore. The crystals occur in cubes, and in combinations of this form with pyritohedron, or rhombic dodecahedron, and octahedron. The white or grey colored arsenides show a tendency to form globular or spheroidal masses, with a radiated structure. Some of these masses in the calcite have a diameter of over ½ inch. The ore is at times somewhat porous, spaces being left between the globules, which are tarnished almost black on their surfaces. Where not coated with cobalt bloom, the weathered surface of the ore has a dark color, not unlike that of the wall rock. On a fresh surface the more massive ore resembles mispickel, but is somewhat darker in color. Small grains of quartz are found sparingly in the ore.

A deposit carrying galena and copper pyrites lies a short distance southeast of vein No. 2. Very little of its surface is uncovered and no analyses have been made of the samples collected. Grains and small masses of copper pyrites were seen in the slate in the railway cuts in the vicinity of deposit No. 1.

Ore body No. 3 is similar in character to No. 1. It lies at the southern edge of Long lake. The ore consists of native silver, smaltite and cobalt bloom, and, in all probability, niccolite also.

Vein No. 4, although having the smallest width of the four, is, in many respects, the most interesting of the group. Here a perpendicular bare cliff of rock, 60 or 70 feet high, faces west. The vein, whose width averages not more than 8 inches, cuts this face at right angles, and has an almost vertical dip. The vein is weathered away, leaving a crack in the face of the cliff 2 feet—in some places 4 or 5 feet—in depth. When I saw it first it had not been disturbed. Thin leaves of silver up to 2 inches in diameter were lying on the ledges, and the decomposed vein matter was cemented together by the metal, like fungus in rotten wood. It was a vein such as one reads of in text-books, but which is rarely seen, being so clearly defined and so rich in contents. It was found impossible to get a fresh sample of the ore with the prospecting pick, the vein being so much decomposed. The weathered specimens, however, in addition to the native silver, contained cobalt bloom; and the unaltered ore will be found, in all probability, to consist of smaltite and niccolite, in addition to the silver. It may also be added that, in one part of the vein, a distinct banded structure was noticed. Across a distance of 8 inches there were twelve or fourteen layers of ore lying parallel to the walls. At the bottom of the cliff the vein cuts thin, banded, dark grey or greenish—at times almost black—slate, which has a slight dip. This slate passes gradually, so far as could be determined from the steep character of the cliff, into coarse breccia-conglomerate in the upper part. The fragments in the conglomerate consist of quartz, slate, granite and other rocks.

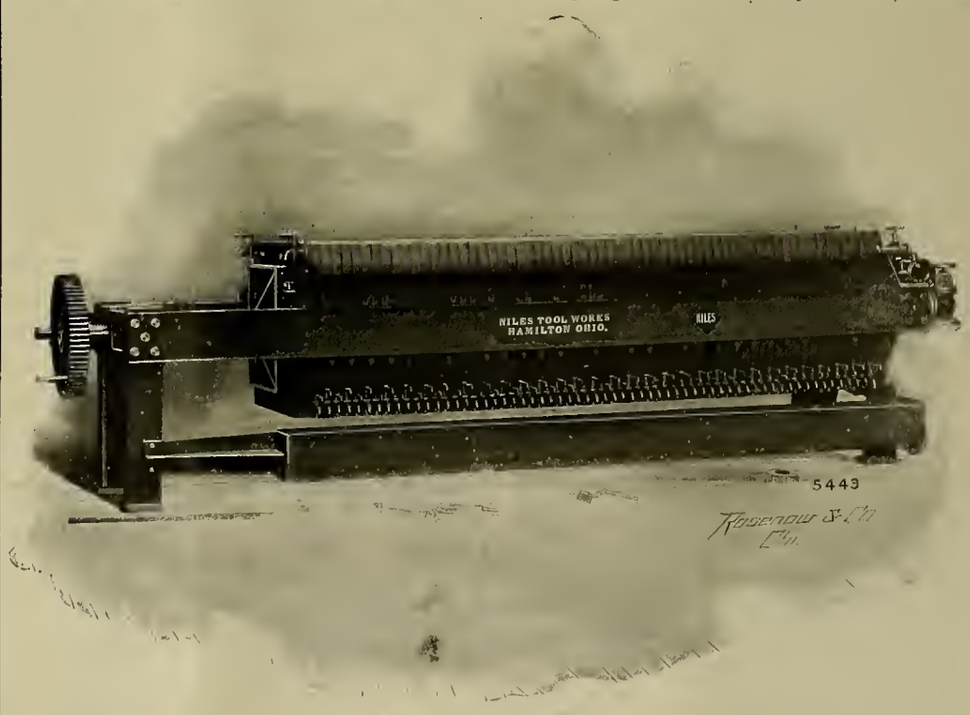
On some of the weathered surfaces of the native silver specimens there are small, black, spheroidal masses, with little luster. These appear to be the hydrated oxide of cobalt, heterogenite. Some of the deposits on the silver resemble asbolite. The carbonates of cobalt and nickel are also probably present. Antimony and sulphur have been detected in the ore of veins 1 and 2. Detailed analyses are required to determine the character of some of the silver-bearing minerals which are present in small amounts. Bismuth, copper and manganese, in an association of ores such as we have in these deposits, are to be looked for.

The recently discovered ore bodies lie about 90 miles northeast of the town of Sudbury, in the vicinity of which are situated the well-known nickel mines. The ore of the latter is of a different character from that of the Haileybury deposits, being essentially pyrrhotite and copper pyrites. The rock associated with the Sudbury deposits, which are not veins, but deposits of irregular shape, is norite. The Sudbury pyrrhotites carry a small percentage of cobalt in addition to nickel. The minerals niccolite, danaite, and other arsenical compounds, have been found in some of the Sudbury deposits, but only in small quantities.

On the Quebec side of Lake Temiscaming, about 9 miles to the northeastward of the Haileybury deposits, an ore body, known as the Wright silver mine, was discovered years ago by some of the early explorers of that region. During recent years this deposit has been worked for its lead and silver contents. The deposit is unique in character, the wall rock being Huronian breccia-conglomerate, the fragments in which are, at times, cemented together by argentiferous galena. Silver-bearing galena with copper pyrites is also found on an island in Cross lake, which lies southeast of Lake Temagami, and at Lady Evelyn lake.

Filter Press for Gold Slimes.

Herewith is illustrated one of six filter presses for gold slimes, built by the Niles Tool Works Co., Hamilton, Ohio, for a Mexican mine. As is frequently the case in mining work, the machines had to be brought to their destination by mules, and they are specially designed in sections of suitable weight.



Filter Press for Gold Slimes.

The press has sixty chambers and has passages for the wash water and washings placed in projecting flaps, with the intent that no filtering surface be wasted. The fixed head is built up of cast iron sections, with necessary flanges for all pipe connections. The sliding head is made up from steel plate, with a central casting on which the screw spindle bears, and both heads have cast iron half plates bolted to their faces. The side bars are deep steel channels, and the discharge trough, which receives both the filtrate and the washings is also made of sheet iron for lightness.

Phosphorescent Sphalerite.

Written for the MINING AND SCIENTIFIC PRESS by ARTHUR S. EAKLE, Ph.D.

Much interest and curiosity has lately been aroused through the discovery of some ore in Mariposa county, Cal., which exhibits a train of light or phosphorescence when scratched with a knife blade, or even with the finger nail. This very striking phosphorescence has led some persons to form the erroneous belief that it is due to the presence of the new and wonderful element, radium. The California Radium Gold M. Co. is the title of a company recently organized to mine the ore, although the radium content of the ore is wholly supposititious. In order to answer the many inquiries about the ore which have been received from reporters and from the public in general, I give herewith the results of my examination.

The ore consists essentially of three minerals, namely, the sulph-antimonite of copper (tetrahedrite), the sulphide of zinc (sphalerite), or, as it is commonly called, zinc blende, and the sulphate of barium (barite). These three minerals form an intimate, fine granular mixture, as shown by a thin section of the ore, occurring in about the same proportions. The secretary of the company informs me that the ore has been analyzed by various chemists with various results, the only point of agreement being that the ore contains "no zinc." On the authority of one, the ore is pronounced an uranio-sulphate, carrying a high percentage of radium.

Judging from qualitative analyses, blowpipe reactions and from the thin section, at least 25% of the ore is sphalerite, and an accurate quantitative analysis would doubtless show a considerable higher percentage of this zinc mineral. Furthermore, there is no uranium present in the ore. The presence of radium is always detected by its strong radio-activity, and while sphalerite or barite may contain radium, the ore has been tested by Professor E. P. Lewis of the physics department of the University of California, and proved to possess less than the hundredth part of the radio-activity of the weakest uranium compound. He is now making experiments to extend over a long period of time in order to determine its radio-activity. The phosphorescence which has given rise to so much speculation is wholly a property of the sphalerite, as was proved by first extracting the copper mineral by acids and then drying and testing the mixture of sphalerite and barite and finally dissolving out the sphalerite and testing the fine white residue of barite.

The phosphorescence of many minerals, including sphalerite, has long been known, and old works on mineralogy state that some varieties of sphalerite phosphoresce by rubbing, breaking, or scratching with a quill. It is a physical property which has occupied the attention of many physicists, and many theories have been advanced to account for it. In the case of sphalerite it is a frictional phosphorescence, as heating does not produce it. Two pieces of quartz rubbed together in the dark will produce the same effect.

Wonderful electrical properties have also been ascribed to the ore, and demonstrations of its use for storage batteries have been given. I have not seen the experiments in this line, but will suggest that

they can probably be explained through the well-known electrical properties of sphalerite.

The assays of the ore, provided they are reliable, show it to be a good gold-silver copper ore. Possibly the larger part, if not all, of the gold and silver is contained in the tetrahedrite, since this mineral commouly has other bases replacing the copper.

Since this ore was determined, a specimen from Eureka county, Nevada, has been given me, which shows exactly the same phosphoresceuce when scratched. The specimen is a mixture of fine granular galena, sphalerite and barite. The sphalerite occnrs intermixed with the other minerals, and also as intersecting veinlets, ¼ inch wide, of pnre miueral, and this pure sphalerite exhibits even more decided phosphorescence than is obtained by scratching the mixed ore.

Although several European localities have been cited where phosphorescent sphalerite occurs, it seems not to have been observed in this country before, and its occurrence in two different places in very mnch the same association is interesting.

The Manufacture of Gun Cotton and Nitroglycerine.*

Written by BRYANT S. DRAKE.

Pinole, Cal., is a small town located on the shores of San Francisco bay. Its popnlation cousists mainly of the employes of the Hercnles Powder Works. It is half of the plant of the California Powder Co., the other half being at Santa Cruz, where the smokeless powder is made. The plant at Hercules is about 700 acres in extent and is directly adjacent to the bay shore. Both the Southern Pacific and the Santa Fe railroads have switches running into the yards, which facilitates the handling of the snpplies and of the finished products. Four hundred men are employed at Hercules. It includes all of its own auxiliaries, such as electric power, water for fire protection, compressed air and refrigerating plants, and makes its own nitric and sulphuric acids. The finished prodncts are mainly dynamite aud raw gun-cotton, though some black powder is mannfactured as well. The dynamite is used in all of the miuing districts of North America for blasting purposes. The gun-cotton is shipped to Santa Cruz and there made into smokeless powder, which is mainly taken by the United States government for naval nse.

The works are divided into three practically independent portions, viz.:

I. The acid works (sulphuric-nitric).
II. The gun cotton plant.
III. The nitroglycerine plant.

I. In the manufactnre of sulphnric acid (H_2SO_4), sulphur is burned to produce the SO_2. The sulphur is imported from Japan and South America, although there are plentiful deposits of it at Clear Lake, California; at Inferno, in Humboldt county, Nevada; at the Rabbit Hole mines in Nevada; at Evanston, Wyoming, and also in Utah and Idaho. It is cheaper to ship the sulphur some thonsands of miles by water than to freight it a few hundred miles through the monntains, and consequently the deposits in this region of the conntry are practically valueless for the present. Large quantities of sulphur are stored at the works so that delays of considerable periods in shipping do not affect the operation of the acid works. There are five snlphnric acid chambers, three large ones measnring 20x20x90 feet, and two small ones of abont half this size. The chambers are formed of lead sheets "burued" together, and a force of lead burners is kept contiuually occupied on these chambers and the other leaden apparatns abont the works.

For the manufacture of the nitric acid, sodium nitrate is nsed. This is imported largely from Chili, South America, althongh it, too, occurs in the western region of the United States, viz.: In Humboldt county, Nevada, in New Mexico, and at Calico, California. The same factors, however, apply to the trausportation of the $NaNO_3$ as to that of sulphnr. The heating of the $NaNO_3$ is carried on in large iron pots, each pot being provided with an inlet for sulphnric acid and an outlet to the condensers. Breakage occasions considerable waste, and the escaping fumes, which are mainly oxides of nitrogen with some free HNO_3, are sufficient to make one gasp for breath if he happens to be on the windward side of the building when the freshly charged pots are started up. The gas passes through a glass condenser and is collected in large earthen jars. The condeusers are made np of a number of large glass tubes about 7 feet long, set parallel in a frame and inclined at a small angle to the horizon. A stream of cool water trickles down over the tubes continually to effect the condensation. The tubes are kept clear for 6 or 8 inches at each end to enable the man in charge to watch the progress of the operation, which is judged by the color of the fumes and the amonut of condensation. As the fumes begin to bleach out and the condensation ceases, the operation is stopped in order to prevent "bnrning" the Na_2SO_4 in the pot to salt cake and thus make it difficnlt to remove. There are forty-two complete sets of HNO_3 pots and condensers, arranged in pairs and each heated by a set of oil burners which allow of accnrate regulation of the temperatnre.

*Abstract California Journal of Technology.

II. Manufactnre of gun cotton. The cotton previons to its nitration is cleaned and dried at the works. The acids nsed are mixed together the day before use, in order to allow them to come to the proper temperature uniformly and without the use of artificial refrigeration. The materials nsed in manufacture being fairly pure, no especial purification of the acids is resorted to. The exact strengths of the acids used and the proportions in which they are mixed is kept a secret, because it is on these two factors that the properties of the gnn cotton depend. The geueral relations of the two acids are: HNO_3 (sp. gr. 1.45-1.5), 1 part by weight or 1 part by volnme; H_2SO_4 (sp. gr. 1.84), 3 parts by weight or 2.3 parts by volume; cotton 20-30 parts by weight.

The impnrities of the cotton may be either natural or artificial. The natural impnrities are crustations and oily matters. They form unstable nitro bodies which may decompose the gun cotton, thus interfering with its keeping qualities. The artificial impurities are water, oil and dirt. Water will cause local heating and may lead to spoutaneous combnstion, aud wastes the material by weakening the acids. Weak acids may canse incomplete nitration.

The cotton is cleaned from dirt and from knots in the fiber by a machine analogous to a cotton gin and a carding machine. The cleaned cotton is theu immersed in boiling KOH for two or three minutes and dried in a centrifugal machine. After this drying, it is washed with water and again dried, this time at 95° F. The drying is effected by spreading the cotton on wire screens placed one above another and slightly separated to allow free air circnlation. If the cotton is snbseqnently exposed to the air, it gradually absorbs moisture to the extent of abont 6%.

The actnal nitration of the cottou is a comparatively simple matter. Shallow tronghs are arranged for the dipping, and a shelf of wire netting is placed just above to allow the acid draining off to run back into the trough. As the acid is absorbed by the cotton more acid is rnn directly from the store of mixed acids. The cotton is packed in pails and is then thrown into the acid tronghs in large handfuls. The contents of one pail go to three separate troughs. The dipper presses each lot below the surface of the acids by means of a steel fork, and after a few minutes removes the cottou to the shelf to drain while a fresh charge is put iuto the trough below; from the shelf the cotton is transferred to ordiuary stone crocks, each of which is provided with a cover. The crocks are then filled with water and allowed to stand for twenty-four hours in a long trongh, which is kept full of running water to prevent a rise of temperature. The troughs are arranged in parallel rows, and before each dipper are snfficient rows to receive his entire day's outpnt. At the opposite end of the tronghs, the jars are removed after having stood twenty-four honrs, and the excess of water is removed by means of a centrifugal wriuger. The cotton is then thrown into a large tank filled with water and allowed to soak for a time; during the washings the cotton is turned over and agitated every few minutes by hand, the operator nsing either a metal rake, or else his hand and arm, protected by a large rubber gauntlet. After the cotton has been washed for a time, the water is run off and fresh water containing sodium carbonate is introdnced. This neutralizes any residual free acid. A second washing then follows and the cotton is again dried in a ceutrifugal. It is then packed in sacks of 100 pounds each and shipped to Santa Cruz, there to be made into smokeless powder. Some of it is also nsed for charging explosive shells for naval use. The cotton used for this purpose is known as the hexa-nitro.

The major portion of the gnn cotton put ont at Hercules is of the soluble variety or collodion gun cotton. This is made into smokeless powder by an operation which consists of dissolving the cotton in the alcohol-ether mixture, running it into a mixing machine, a cylinder containing revolving blades, evaporating the solvent until the dissolved substance is left in a pasty mass, and then putting this into a press and forcing it through dies in snch a way as to form long cylindrical strips. Some of the strips have a considerable diameter and these are usually pierced by a number of circular holes and cut into short blocks. After drying these are ready for nse in the larger cannon.

The smokeless powder does not detonate but bnrns. The rapidity of combustion depends mainly on the pressure. Berthlot gives the rate of combustion of gun cotton as eight times that of ordinary powder, and states that a pressnre of 160 tons per square inch can be obtaiued by it. The velocity of propagation of the explosion is from 5000 to 6000 meters per second. Water does not interfere with the explosion of gun cotton, in fact wet gun cotton explodes more violently than dry, but the combustion is not so complete.

The chemists at the plaut test each lot of cotton for solubility in the alcohol-ether mixture. For this test the following mixtnre is nsed: Alcohol (sp. gr. 0.805), 1 part by weight; ether (sp. gr. 0.735), 1 part by weight; gun cotton, 1 oz. in 400 c.c. of the mixture.

The amount of moisture, ash and alkaline substances, calorific value, and the temperature of ignition are also determined. Before the cotton is tested it is pressed into circular buttons and dried by a hot air blast. The presence of moisture and ash are determined in the usnal way by drying and ignition. The calorific valne is determined in an ordinary bomb calorimeter. The nitrogeu is determined by means of the nitrometer, the principle of the operation being that when cellnlose nitrates are shaken with concentrated H_2SO_4 in the presence of mercury they are decomposed and all the nitrogen is evolved as oxides. These oxides are collected and measured, and the percentage of nitrogen calculated. Sometimes tests are made to determine whether all the cotton has beeu nitrated or not. This is done by dissolving as much of the cotton as will dissolve in the ether-alcohol mixtnre and then treatiug the residne with ethyl acetate. Between these two solvents all the cellulose nitrates are dissolved aud any nnnitrated cotton is left behind. The temperatnre of ignition is determiued as follows: A small amount of gun cottou is placed iu a test tube and the whole is snspended in an oil bath; this is theu gradually heated, and the temperature at which the gnn cotton flashes is noted. (It shonld be above 180° C.) In practice the oil bath is heated to 100° C. before the emersion of the test tube and cotton.

III. Nitroglyceriue. Explosives of the Sprengel class.

The general process for making nitroglycerine is to add glycerine to a mixtnre of strong nitric and snlphuric acids.

The relative amouuts of acids are approximately: H_2SO_4 (sp. gr. 1.845), 4 parts by weight; HNO_3 (sp. gr. 1.4), 2 parts by weight; glycerine (anhydrous), 1 part by weight.

Most of the glycerine used is obtained from the soap factories and is shipped in iron drums contaiuing 1100 to 1300 pounds. Soap factory glycerine is pure and practically anhydrous and is used directly for uitration without any preliminary treatment. In the actual nitratiou and subsequeut operations, the acids, glycerine and nitroglycerine are transported from place to place in uncovered lead tronghs by the force of gravity. Lead is nsed for the lining of these troughs, because the cold, concentrated, mixed acids act but slowly upon it. Each trough is washed and scrubbed directly after each passage of the products of nitration.

As in the manufactnre of gun cotton, the sulphuric and nitric acids are mixed the day before and allowed to cool. All this mixiug of acids is done by one man, and the streugths and proportions of the mixed acids are kuown only in the laboratory and to the chemists in charge. From the place of mixing and storing the acids are removed throngh an iron pipe, by means of compressed air, to the storage tanks on the summit of the hill where the nitroglycerine mixing honse is located.

(TO BE CONTINUED.)

Character of Cement.

Following are the specifications for cement taken from an article by D. B. Butler, in Cement and Slate:

The whole of the cement shall be pure Portlaud cement, and shall conform to the following tests:

FINENESS OF GRINDING.—To be such that when sifted throngh a standard sieve having fifty holes per lineal inch there shall uot be more than ½% by weight of residue; when sifted throngh a sieve having seventy-six holes per lineal inch, there shall not be more than 5% of residue; and when sifted through a sieve having 100 holes per lineal inch, there shall not be more than 12% of residne.

TIME OF SET.—A pat of neat cement, gauged with the minimum of water, at the normal temperature (60° F.), and placed on a glass or other non-porons slab, shall not commence to set in less than eight minntes, or take longer than five honrs to set hard.

SOUNDNESS, OR FREEDOM FROM EXPANSION AND CONTRACTION.—A pat submitted to moist heat and warm water in the Faija apparatus for soundness, at the usnal temperatnres, viz., 110° F. and 120° F., respectively, shall show no cracks or signs of expan sion after twenty-four honrs.

TENSILE STRENGTH.—Briqnettes of neat cement, ganged with the minimum of water, on a non-porous bed, and placed in water twenty-four honrs after gauging, shall carry an average tensile strain of not less than 550 pounds per sqnare inch after three days, 450 pounds after seven days, and 550 ponnds after twen ty-eight days from the time of ganging.

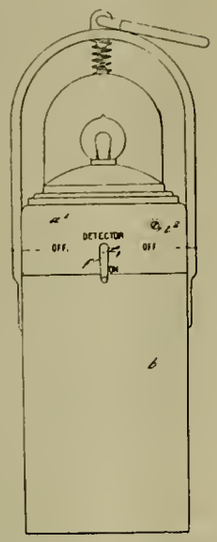
Briqnettes composed of three parts of standard sand to one part of cement, by weight, treated as above, shall carry an average tensile strain of not less than 150 pounds per sqnare inch at seven days, and 250 pounds at twenty-eight days from the time of gaugiug; bnt no matter how mnch greater strength may be developed at the earlier stages, both neat and sand briquettes must develop an increase of at least fifty ponnds between each date.

Mining and Metallurgical Patents.

PATENTS ISSUED JANUARY 12, 1904.

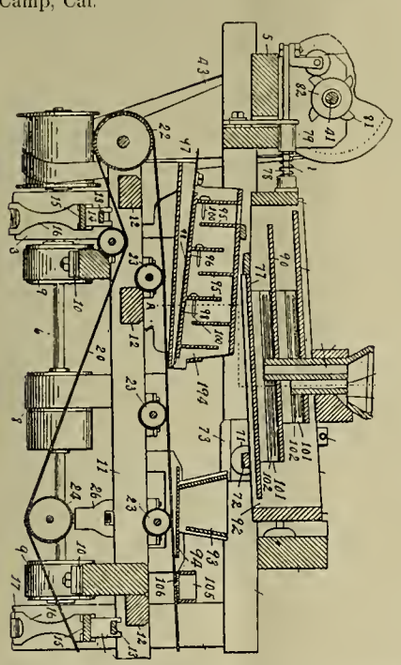
Specially Reported and Illustrated for the MINING AND SCIENTIFIC PRESS.

MINER'S ELECTRIC LAMP.—No. 749,500; H. G. Prested, Camden Town, England.



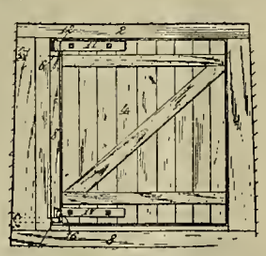
Miner's electric lamp comprising diffusion device, lamp and circuit short-circuiting lamp so as to render latter useless when diffusion device is in action.

CONCENTRATOR.—No. 748,819; L. R. Tulloch, Angels Camp, Cal.



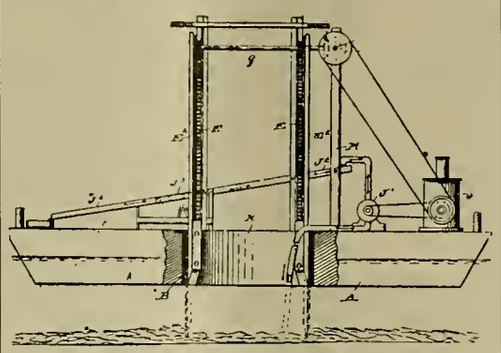
In concentrator, combination of belt, means for oscillating same, percussion box, means operated with oscillating means for shaking box longitudinally of belt, box comprising hopper into which material is fed, vertical series of tables onto which material is successively distributed, and individual longitudinally slotted plates above tables for distributing material evenly over tables.

HINGE FOR MINE DOORS.—No. 749,561; T. Jeffrey, Pittsburg, Ky.



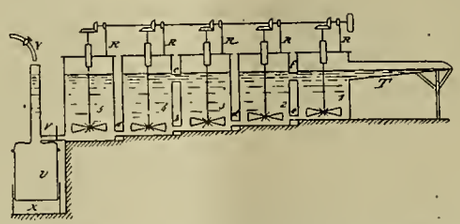
Combination with door for mine galleries of pair of hinges each comprising a yoke to straddle door, and eye member projecting beyond yoke, upper member being provided with single eye and lower member with pair of eyes, pair of pintle members secured to door frame and projecting beyond same, upper member being provided with single pintle and lower member with pair of pintles, and filler block interposed between two pintle members and bearing against under side of upper member and upper side of lower member, filler block performing double function of closure for space between inner edge of door and its support, thereby to prevent escape of air, and to transmit strain from the upper pintle member to lower pintle member, thereby in positive manner to prevent sagging of door with attendant danger of same binding in its frame.

HYDRAULIC GOLD MINING.—No. 749,197; F. J. Hoyt, Chicago, Ill.



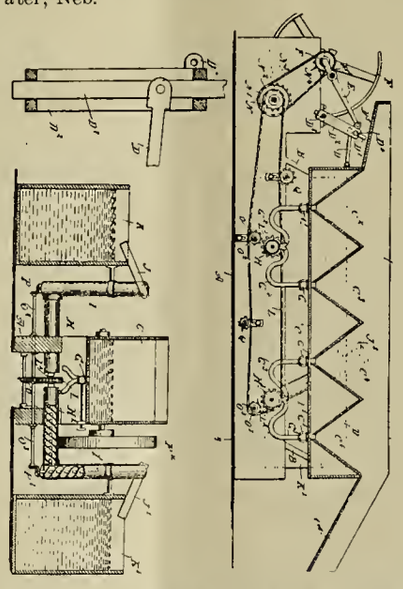
In hydranlic mining apparatns, float or scow provided with opening throngh its deck and bottom to water, sectional caisson adapted to fit within and extend through opening in such manner that in its working position its top is always on level with deck, common mechanism for lowering caisson to river bed and for forcing it therein to any desired depth in one continuous operation and for raising caisson from river bed, and power means for driving mechanism.

PROCESS OF TREATING COPPER ORES.—No. 748,662; M. G. Sebillot, Paris, France.



Process for extracting pure metals from mineral ores, consisting in treating ores with sulphuric acid at evaporating point of latter, without roasting, to form sulphates, condensing snrplus acid fnmes, and lixiviating sulphates in successively deeper baths under constant agitation in current flowing in direction opposite to progress of ores.

CONCENTRATOR.—No. 749,706; D. M. Storey, Weeping Water, Neb.

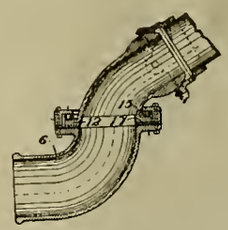


Concentrator, comprising box having rocking motion and provided with transversely extended V-shaped riffles, means for operating box, settling tanks arranged at side of box and adapted to be filled with water to level of water in box, conveyor for conveying concentrates from bottoms of forward riffles to one of the settling tanks, conveyor for conveying concentrates from bottoms of rear riffles to the other settling tank, and means for operating conveyors from box-operating means.

ORE GRINDER.—No. 749,630; W. G. Phipps, Stockton, Cal.

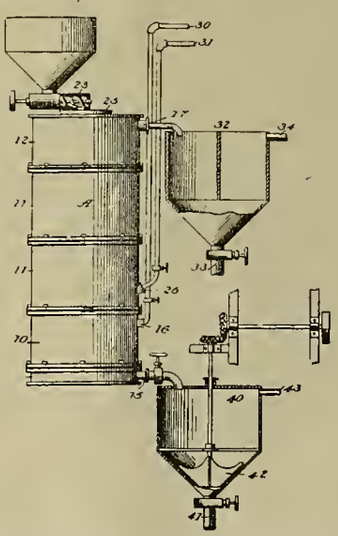
In ore grinder, plate in form of circle, or part of circle, radial cutting edges extending inward toward center of plate, plate being hollowed out or dished between cutting edges, cavity commencing at point slight distance inward from periphery and gradnally deepening toward center, each of cutters being beveled from point about midway of length to inner ends, annular beveled surface formed upon back outer edge of plate, periphery of plate being formed with sharp edge by reason of annular beveled surface on back of plate.

HYDRAULIC NOZZLE AND JOINT.—No. 749,417; J. A. Yeatman, San Francisco, Cal.



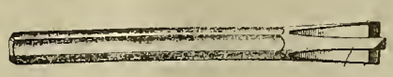
Improved hydraulic discharge pipe comprising fixed and movable pipe sections, with flanges upon contiguous ends; annular thrust collar bolted to one of the flanges and having flange projecting inwardly over uppermost of pipe flanges; anti-friction bearing between the last named flanges; flexible disk secured between pipe flanges, disk having its inner edge projecting and turned over the joint between flanges whereby projecting portion will be forced against inner wall of pipe sections and joint to prevent leakage at latter; discharge pipe jointed to movable pipe section; cap fitting over end of discharge pipe and having inwardly extending flange; and removable annulus fitting cap from inside and clamped between flange thereof and end of discharge pipe.

PROCESS OF LIXIVIATING ORES.—No. 749,700; P. Naef, New York, N. Y.



Method of lixiviating ores and other pulverulent materials, which consists in passing ore downward in thinly divided layers in zigzag course throngh ascending stream of leaching solntion, whereby ore and solntion passing in serpentine course in opposite directions prodnces prolonged and intimate contact of ore and solution.

ROCK CUTTING DRILL BIT.—No. 749,369; L. Durkee, Denver, Colo.



In rock cutting drill, combination of suitable drill shank having chuck holding end, with rock cutting end, comprising four radial ribs extending axially with shanks, and forming integral part thereof, two oppositely disposed set of ribs, one set of which sets extends beyond opposite set a short distance and forms a chisel-shaped cutting edge at end of drill bit, and having opposite corners of two longest ribs beveled in opposite directions, and inverted V-shaped cutting edge at center of chiseled end, and a suitable cutting edge on terminal edges of two opposite shorter ribs.

Mining Summary.

SPECIALLY COMPILED AND REPORTED FOR THE MINING AND SCIENTIFIC PRESS.

ALASKA.

Superintendent B. Thane, of the Eagle River M. Co., operatiug near Juneau, says he is putting in a 1700-foot aerial tramway to connect the main tuuuel with the 10-stamp mill. The mouth of the tunnel is 7 miles from the beach, in a heavily timbered district, and tho road runs through a boggy country. The stamp mill is completed and a 6-drill compressor put in, also saw mill and planer, with seven buildings for bunk and boarding houses, residence and store rooms put up. The property was bonded last July by Georgia men.

G. M. Hill of Fairbanks, coming out from the Tanaua overland to Valdez, says there are 2500 miners in aud around Fairbanks on the various creeks. There are 250 meu at work on Fairhanks creek and as many more on several of the other creeks near there. Pay dirt was found, running from 5 to 15 cents per pan on most of the claims. Most of the work is done on the lease system, in come cases there being as high as six and seven leases on one claim. Provisious are high, flour bringing $35 per sack, and everything else in proportion excepting meat, which is plentiful owing to two steamers which were loaded with meat for Dawson, were frozen in at Circle City, and the bulk of this meat has been taken overland to Fairhanks. Hill says the town is building up and many of the buildings are substautial. The best way to go in is by Dawson, then over the ice to Circle City, thence overland to Fairhanks. There are road houses every 25 miles and the roads are good. J. Joslin is putting in a tramway, connecting the mines with Fairhanks.

ARIZONA.

Cochise County.

The Columbus C. M. Co. has heen incorporated by S. J. Miller, M. B. Earnhart and W. A. Morrison, with principal places of business at Tombstone, Ariz., aud Columbus, Ohio.

Gila County.

The Pasquale Nigro miue, near Globe, continues shipping ore.——In doing assessment work on one of their claims in Lost gulch, the Black Warrior C. Co. Amalgamated, uncovered 2 feet of ore carrying black copper sulphide.

Construction work at the Old Dominion mine at Globe continues. Of the several plants, the smelter and converter building, which is of steel, is about completed. The three smelter jackots, each 44x180 inches, have been put up. Excavations for the converter fouudations have heen finished and work on tho foundations hegun. The electric crane, with capacity of forty tons and having an auxiliary hoist capable of liftiug ten tons, was given a test run last week. The generator to operate the craue will he in the power house at the smelter. There will also he two electric locomotives, one to haul the slag and the other to haul charge cars. Three engines aro being set up at the smelter power house, two to generate air for the furnaces and one for air for the converters. The blower will have capacity of 20,000 cubic feet of air per minute. The graders are excavating for the flue dust chamber, hack of and running north from the smelter building. At the mine the steel boiler house is up and the power house two-thirds finished. The hoist, a duplicato of the one in use at the old shaft, has heen set up. Later, the old hoist will he set up at the new shaft. The new four-compartment shaft is down 660 feet, or 30 feet helow the tenth level. Thoy are cutting the tenth level pump station, which will be 58 feet long by 14 feet wido, and 12 feet high. Steel for the head-frame has been shipped.

The Old Dominion mine during Decemher made the largest output of copper for any like poriod in the history of the mine, says Superintendent F. W. Hoar. There were 1,200,000 pounds of refined copper and 110,000 pounds of sows, running 98% copper, produced. The output for January will be less, as only one furnace is in operation at present, though another furnaco may he blown in later.

Graham Couoty.

G. Stevens reports the findiug of more lead ore—having opeued up a 6-foot shoot—in the lime on Comstock No. 2 mine, near Clifton. He is sacking the ore for shipment. In his Black Dyke claim at Garfield gulch he has started a drift aud is in 30 feet on the vein, 25 feet above the gulch, at which point the vein is 4 feet wide. He says he has 2 feet of quartz carrying copper-silver values, and 2 feet of porphyry running $5 gold per ton.

The Standard mines tramway, near Clifton, is in operation and is handling an averago of eleven tons an hour. It is expected the mine will ship regularly three times a week.

Considerable new timbering is being done in the Longfellow mine, near Morenci. The numher of men at work has heen increased.——Two electric machine drills are being put in operation in the tunnel driving to connect Old Yankee and West Yankee mines. —— Superintendent Hunt of the Detroit C. Co. concentrator, near Clifton, is putting in an oil concentrating machine to test the concentration of their sulphide ores by oil.

Maricopa County.

(Special Correspondence).—The Angel mine, near Wickenburg, has suspended operations temporarily.——Work will be resumed at the Gold Quarry mine this week.——H. A. Stevens is working twelve men on his group northeast of Morristown.——The Arizona M. & Dev. Co. is working men on the Montezuma lead mine. The Montezuma shaft is being cleaned out, and a road is being built from the Hassayampa river to the Montezuma shaft.

Wickenburg, Jan. 17.

(Special Correspondence).—While drilling a well in the Salt River valley, near Phœnix, a vein of coal 3 feet in thickness was struck last week.

Phœnix, Jan. 17.

Mohave County.

The Sopresa G. M. & M. Co. has been organized, says the Kingman Miner, and work will he started on several of the claims owned by the company, 4 miles south of Kingman. The company owns the Blake mine, which is said to have a hody of $10 ore which can be cyanided at a profit.——The reorganized Elkhart M. Co. has started up work on its group, near Chloride.

Yavapai County.

The second of the 500-ton furnaces at the smelter of the United Verde miue, at Jerome, is in operation. The smelter has equipment of two 500-ton furnaces and a 250-ton water jacket furnace, and all are turning out bullion to full capacity.

Manager Smith of the Dividend Con. G. M. Co., operating near Phœnix, says he has surveyed a line for a tramway from the hoisting plant ou the Dividend claim to the mill. Timhers are on the ground for enlarging the mill for more ore bins and to huild a hoisting frame.

The Rich Hill M. Co. has heen incorporated hy C. L. Hoyden, J. C. Herndon and T. G. Norris of Prescott.

Yuma County.

Three companies have resumed work in Quartzite district since last season's shutdown. The Valenzuela M. Co., R. Darling president, is working ten men. B. G. Smith has started work on the Plomosa group and Apodaca & King are doing development work on the middle camp properties. The Carter-Wheeling group has been bonded to R. Darling for $25,000 and G. Norton & R. Hathaway have bought an interest in the Emma group aud are developing the property.

ARKANSAS.

Marion County.

A strike of zinc ore was made last week on the Blazing Star mine, uear Yellville. The ore is a higb-grade blende. There are three cuts on the mine, each 30 feet deep, all sbowing ore.

CALIFORNIA.

Amador County.

At the Bunker Hill mine, near Amador City, work is progressing, says Superintendent Downes. He expects to have the mill ruuning by Feh. 1.

Work on the Argonaut, adjoining the Kennedy mine at Jackson, is progressing, and the number of men is heing increased. A station is heing cut at the 1800-foot level, and drifting to the ledge will be started. In additiou to this the work of unwatering the lower levels continues and when finished sinking will he resumed.

The Hooligan mine, owned and operated hy the Hooligan G. M. Co., is in Pioneer mining district, near Defender. The owners of the Hooligan have completed a 140-foot tunnel which cuts the ledge at depth, showing values in gold and silver. T. Smith is part owner.

Superintendent E. Lynch of the Keystone mine at Amador City says he has ore blocked out and he will remodel the plant to facilitate handling and treatment. The skips have been replaced by ones of greater capacity. Beside the hoiler plant another huilding is heing erected for two receivers for compressed air for the drills and pumps. In the shaft at the 800-foot level a pump capable of liftiug 70,000 gallons of water per uine hours is heing set up. This pump will take the water from the sinking pump and lift it to the surface. The treatment plant consists of two mills equipped with twenty and forty stamps, respectively. Tbose used in the latter, however, are not considered heavy enough for the work required, says the Ledger, and foundations are being made to move this mill hack on a line with the smaller one and put in a like number of heavier hatteries.

At the Oneida mine, near Jackson, Manager Hampton is preparing to put in a pump capahle of lifting 200 gallons of water per minute 2400 feet. For the present, however, it will only be required to hoist water from the 2100-foot level to the pump at the 1200-foot level, which lifts it to the surface. In addition to this, 400 feet north of the shaft at the 2000-foot level a winze is heing sunk to the 2200-foot level. A steam hammer driven by a 4-inch cylinder and with an 18-inch stroke has heen put in at the blacksmith shop for heavy forge work.

Butte County.

Marysville reports say the California Debris Commission will again proceed with the construction of debris restraining barriers in the Yuha river east of Marysville. Round piling will be used instead of sheet piling. S. Montgomery of Woodland, who had the coutract to build harriers Nos. 1 and 2, will construct the barrier (No. 1) which the commission has decided to have rehuilt. The specifications for this harrier, as originally drawn up, called for the use of sheet piling, hut it was found impossible to drive the planks into the thick hed of cobbles in the river, and the attempt was abandoned. Then fascines of brush weighted down hy rock were tried. No action has yet been taken as to rehuilding barrier No. 2. The divorting canal through Daguerre Point is making progress. About 12,000 cubic yards of gravel are removed daily and no rock has yet heen struck. Two locomotives and two trains of twelve cars each are in use, and another locomotive will he put on so a third traiu can be operated.

Calaveras County.

The 5-stamp mill at the Jack Rahbit mine at Dogtown, uear Augels, started up last week. Tbe mine has been unwatered and ore is heing taken out.

The Ohio mine at Douglas Flat (the Chase mine), is being opeued up by its owners, Orth, Capella Bros. & Valente. They have just been ground-sluicing away a cut in the old diggings to enahle them to start drifts into the mine.

The stamps are dropping in the mill of the Stockton Hill mine, near Mokelumne Hill, the 4000-foot pipe lino to carry water to the mill having been finished last week. The gravel in the mine continues to prospect satisfactorily, says Superintendent Robinson.

A Bucyrus gold dredger will be put in operation this week on the Calaveras river at Jenny Lind, having been built by the Hammon M. Co. At this point tbe river bed is 3000 feet in width, and tbe company owns 400 acres of placer ground. Two more dredgers of the same pattorn will be built to work on the ground. The power to operate the machinery will be furnished by the American River Electric Co.

The Old Stiff placer mine, near Vallecito, on Balaklala hill, is heing worked by Superintendent Gleason, who says piping is giving satisfactory results. Next month piping is expected to be well into the main channel.

It is reported the Mutual M. Co. will begin operations at the Lucky Boy mine on Dry creek, 2 miles from San Andreas. The owners of the property are Boston, Mass., men. It is said that oil-buruing fixtures will be put in for the boilers, doing away with use of wood.

During the past year considerable development work has been done on the Lew Wallace group of miues, near San Andreas, says the Chronicle. The work consists mainly of tunnels. The group consists of five contiguous claims. Quartz carrying gold and sulphurets has heen opened up. Superintendent Voorhies is building a wagon road to the Lew Wallace claim, and machinery will he put ou in the spring.

Fresno County.

Last week at Coalinga well No. 1 of the Pleasant Valley F. Co. hegan spouting oil through a 3-inch tuhing at rate of 1400 barrels per day. It is throwing a steady stream of 700 barrels per day of a 17.5° gravity oil. The unexpected increaso in the productiou necessitated building additioual temporary storage reservoirs. Plans are being made to drill at least four more wells in addition to Nos. 1 and 2.—— The Hanford Oil Co. has finished grading and is now hauling lumber for rig No. 7. For nearly a year the company has kept one string of tools running steadily. Five wells are being pumped, one drilling, another rig going up.

Kern County.

The Reynolds Oil Co. has been organized hy Bakersfield men aud will operate at Sunset. The directors are J. A. Flood, R. Barkes, J. Henry, W. K. Osmer, W. O. Clay, C. & G. A. Reynolds.

A. T. Stewart of the War Eagle group reports he is sinking a 100-foot shaft on the Little Emma mine, near Randsburg, to get the continuation of the Butte Lode vein.

Mariposa County.

L. E. Hanchett, manager of the Sweetwater mine, near Mariposa, says the company operating the mine has discontinued operations until an air compressor can be put in, after which drilling will be done with machines.

Nevada County.

The stamp mill at the Kentucky Ridge mine, near Nevada City, is in operation, says Superintendent A. Halsey. Five stamps have been put in and room left in the building for five more. Men are at work in the mine stopiug ore.

Development work has begun on tho Lamarque quartz mine, near Grass Valley, uuder superintendence of C. Brockington, who is also superinteudent of the Orleans mine. A vertical shaft will be put down. The Lamarque adjoius the North Star mine on the north and the Central on the east. The property is bonded to J. Rosenfeld's Sons of San Francisco. In addition to the miniug locations they have also bought the McDonald ranch, adjoiniug, which they propose to use for millsite and dumping purposes.

The Brunswick M. Co. near Grass Valley has succeeded in draining the mine of the water which had accumulated, says the Tidings, by operation of two electric pumps. Superinteudent Mallon says the mino has been pumped dry to the 1200-foot level. The shaft reaches 50 feet helow this level, as a sump. Here a 10-inch Cornish plunger and two steam pumps are kept in operation. Men are blasting out for a station at the 1200-foot level for the third electric pump. The water which is coming from that level will he conducted through hoxes to a tank which will be built. A dam has also been built at tho 1200-foot level. This will be used in case of emergency, whenever the pumps are idle. Since the water has beon pumped out an atteunpt was made to start the raise above tbe 1200-level, hut the work had to be abandoned. It was in this raise that the water, which resulted in the suspension of underground operations, was struck.

San Diego County.

Ten miles soutb of San Diego, and east of Chula Vista, four test holes have been drilled, preliminary to the sinking of an oil well. Indicatious are said to be favorable for getting oil. The Chula Vista Oil Co. has been organized to develop the ground. J. L. Wild of La Mosa is interested.

Santa Clara County.

Near Sargents tho Watsonville Oil Co. of Watsonville has decided to pipe oil to rail line or to tide water (to tide water if satisfactory terms caunot be made with the railroad company). Two wells are producing 300 barrels of oil daily. The company will increase development of Sargent district. They will put in two more drilling rigs. J. S. Menasco, F. A. Kilburn, W DeHart, R. W. Eaton and O. D. Stoesser are directors.

Tuolumne County.

The Mt. Jefferson mine at Groveland will sink the shaft another 100 feet.—— The tramway between the Two Brothers mine and the Mack mill, near Groveland, is in operation.——The mill at the Mohican mine, near Groveland, is shut down temporarily to make repairs. Work continues underground.——Ground has been prepared for the 20-stamp mill at the Belle mine, near Tuttletown. The shaft will be sunk from the 530 to the 600-foot level. ——The mill at the Longfollow mine, near Groveland, is expected to he put in operation next week.

Men are at work at the Florida mino near Marble Point, near Carters, and are crosscutting. The ground is hard and progress slow. The mine is owned by H. M. Bacon of San Francisco.

COLORADO.

Boulder County.

The Big Six M. Co. is planning development on its group on Chittenden mountain, near Eldora. It has resumed work on the crosscut tunnel which is heiug driven from point on northeast slope of Chittenden mountain, abovo tho north fork of Boulder creek. The tunnel has heen driven 140 feet and will cut the Grauite Cliff and Hidden Treasure veins at a depth of 700 to 800 feet below the surface, with tunnel 400 feet in length. The Hidden Treasure vein has 7 feet of ore exposed in the upper workings, says the Eldora Record, with average values of $20 per ton. The ore is iron sulphide, with copper and streaks of tellurides. The Granite Cliff vein shows 2½ feet of the same class of ores, with average values of $15 per tou.

Chaffee County.

(Special Correspondence).—The West Gold Hill M. Co. has cut a 20-foot hody of

oxidized ore, averaging $12 per ton, in No. 2 drift of the Sellers claim. Tests made show the ore can be handled by cyanide treatment and the company will build a mill the coming summer. This company has a group comprising 200 acres which they have been developing the past two years. They have opened on the contact bunches of ore at intervals of 150 feet for 3000 feet. They have also opened up a 5-foot vein in the granite below the lime, a carload of which is being gotten out for shipment. Samples show $20 per ton. The nearest shipping point is 9 miles, but the main road is to St. Elmo, a distance of 14 miles. The Taylor Park Railroad is driving a tunnel through St. Elmo Pass and expects to have the railroad in operation into Tin Cup before Jan. 1, 1905. This will open up the Taylor Park country by railroad. The railroad has been guaranteed 900 tons of ore daily when the road is completed. The company owning the railroad also owns the Enterprise mine.

The Brunswick Co., owning the Jimmy Mack mine, is driving the Blister Horn tunnel.

Tin Cup, Jan. 18.

A silver strike is reported made in the Netsie Castley claim, in North Fork district, by J. H. Akin of Shavano and E. W. Carpenter of Salida. Assays show 75 ounces silver, 20% lead and $3 gold in the surface ore, of which there is a 4-foot vein in sight. The Netsie Castley is near the crest of the continental divide, near the Gunnison line. It is west of Shavano, 10 miles north of Marysville. It adjoins the Michigan group and is north of the Billings tunnel.

Clear Creek County.

The Mendota mill, under management of Stevens & McGarth, near Georgetown, treated during the twelve months of 1903 a total of 20,000 tons of ore. The material was from the dump, with a portion of same from the old stopes in the Mendota mine. The ore is concentrated on an average of nine to one.

The Lebanon mine, on Republican mountain, near Georgetown, taken over by J. Owen of Idaho Springs, is being reopened. Owing to a cave-in that occurred near mouth of tunnel, the workings will be retimbered. J. Maxton is superintendent.

The St. John M. & M. Co. has been incorporated by C. A. Frost, E. W. Lippert and S. A. Westo, with principal office at Idaho Springs, and operations will be carried on in both Clear Creek and Gilpin counties.

The Colorado Central group, being operated by the Aliunde Con. M. & M. Co., near Georgetown, has thirty-five claims. During the past year only a moderate production resulted, as the management was carrying on development work which had been mapped out. A winze is being sunk from the 1000-foot level, which will be driven a distance of 75 feet, at which time a drift will be run to cut under the main ore body of the Colorado Central vein. There are three tunnels on the group—the Marshall, Ocean Wave and Equator. The Marshall has been driven 1800 feet and has attained depth of 500 feet. The Ocean Wave has been driven 3400 feet and has an additional depth below the Marshall of 200 feet. The Equator connects with the Ocean Wave and the ore is raised to the last named tunnel level, from which point it is transported to the dump. The holdings of the Aliunde Co. are on Leavenworth mountain. M. Tong is resident superintendent.

The Clear Creek & Gilpin M., M., P., T., D. & T. Co. is arranging for a plant of machinery on its Torrey tunnel, near Idaho Springs. The plant will have 100 H. P. boiler capacity and a compressor capable of operating from six to ten drills. The tunnel has been driven 450 feet by hand, but driving operations are temporarily suspended. Work is being devoted to developing the three veins already cut. The company owns a group of forty-two claims in the Empire and Fall River districts, which will be cut in the first 3800 feet of driving. After completion of development of these claims, it is intended to continue the tunnel into Gilpin county as a transportation tunnel.

The Brighton mine of the Pittsburg Con Co., at Freeland, resumed operations last week after several months of idleness. The shaft is 300 feet deep and will be continued another 100 feet.

At the Centurion tunnel, near Idaho Springs, which suspended driving when the coal strike was declared, work is confined to developing its veins. The tunnel is in 1000 feet and seven veins have been cut. A number of leasers are at work both in the tunnel and in the upper workings.

The Dives, Pelican and Seven-Thirty groups of mines, on Brown mountain, near Silver Plume, have been sold to New York and Kentucky men for $500,000, says Manager R. C. Vidler. Work is expected to be in full blast next month.

Custer County.

A copper and silver strike has been made in a 40-foot tunnel near the Bassick mine by Blunt Bros. of Florence, says the Times. The ore shows assays of $40 per ton.

The McCraney group of three claims is under bond and lease to G. W. Avery et al. of Custer City (Rosita P. O.) for $20,000 for three years. Work is being done at the 100-foot level. The ore carries copper and lead, with an excess of iron, and runs 20 ounces in silver and $4 in gold. The mine is on the western end line of the Dolomite lode and is equipped with a steel whim for hoisting. The Evening Star is also under lease and bond to Avery et al. Ore is exposed at four openings on this vein. No 1 shaft at the south end is down 170 feet. No. 2 shaft is down 40 feet. This group is west of the McCraney.

The Florence M., M. S. & R. Co. has given a bond and lease on the Florence group of seventeen claims, near Querida, to Blunt Bros. and J. Kendall. Arrangements have been made to work the group and ore will be shipped.

Gilpin County.

The Nevada Con. G. M. Co., of which T. Marks of Denver is president, will replace the 50-ton mill on its holdings near Nevadaville with a 100-ton mill that will have roller crushers. The milling ore is said to average $10 a ton. They have smelting ore that averages $45. There has been no stoping done, but there are 2 miles of workings and the shaft is down 600 feet. Arrangements will be made for saving the zinc and iron as well as the gold values in the ore. A Blake type crusher and a Huntington mill, with amalgamating plates and tables, will be put in. In the Novada Con. there is one vein 23 feet wide, says Manager A. M. Rucker. There are 240 acres of mineral land owned by the company and it is expected to make it 400 acres. The mill superintendent will be J. E. Ehrhardt.

The Alger-Kansas mine, owned by J. Tascher, on Quartz hill, near Nevada gulch, near Central City, will be reopened. Eastern, as well as local, parties are interested in a lease and bond with W. C. Carnegie in charge. The machinery has been overhauled, the buildings repaired and work of retimbering the shaft has been started. —— The James Heury mine, owned by Denver men, on north slope of Gunnell hill, will also resume. The plant has been overhauled. Preparations are under way for increased developments, with W. Ballantyne as superintendent.

Colorado Springs men are arranging to take hold of the Success-Meeker group in Lake district, near Central City, and will form a company to operate it under lease and bond. It is equipped with top plant and buildings. The ores carry values in lead, gold and silver.

Manager S. Brereton of the Sydenham M., M. & L. Co., in which Colorado and West Virginia men are interested in a lease and bond on the Maine and Hamlet mines near Central City, says his company intends sinking the shaft on the Maine an additional 200 feet during the next six months. The shaft is down 424 feet. Additional machinery has been placed. Test shipments of milling ores gave satisfactory values, and the smelting ore brought $40 per ton.

The Hunky Dora mine, on Bobtail hill, has been bonded and leased to Denver and Eastern men, who have organized the Moritoria G. M. Co. The shaft building has been repaired. The work of retimbering the shaft is under way. The total depth of the shaft is 320 feet. New levels will be opened up at 100 and 250-foot depths, and developments increased. The company has leased blocks of the upper workings above the 100 level to local miners, and they will make shipments. The Hunky Dora is between the Fisk-Cook group and the Running Lode. ——Another property to resume is the Caledonia, in Lake district, owned by the New National T. M. Co., which has bought a group east of Black Hawk and starting on North creek, going towards Russell district, in Gregory, Enterprise, Lake and Russell districts. The Caledonia has been partly developed by a shaft 420 feet deep. The company will extend the levels. They will also deepen the shaft, which will be cut by the main tunnel to provide ventilation.

E. P. Young & Co., of Denver, have a lease and bond on the Vanderbilt group of claims, south of Contral City. They have put up a building on the Mountain lode and are sinking a shaft, which has reached a depth of 50 feet. They are shipping ore to the stamp mills. They are putting up a shaft building and machinery on the Pride shaft, which has been sunk to 100 feet. Sinking will resumo in this shaft to develop the entire group.

A strike is reported made last week in the Gilpin-King mine, opened by Lunwall Bros., in Central mining district, 1 mile south of Gilpin and 2½ miles from Rollinsville. They have put up a shaft house and intend working the mine all winter. The vein lies between granite and porphyry.

Gunnison County.

Operations continue on the holdings of the West Gold Hill M. Co., near Pitkin, by driving a tunnel to cut veins at greater depth, which are showing in the upper workings, says the Pitkin Miner. This is a low-grade milling proposition. A 50-ton cyanide mill will be built by the company in the spring.

Hinsdale County.

Work on the Red Rover group, near Lake City, has resumed. Twelve men have been put on and this number will be increasod. A. Harvison is manager and G. Staples superintendent.

Lake County.

The Western M. Co., near Leadville, reports development progressing in addition to steady shipments of ore being made. At the Henriet shaft the old shaft house is being torn down and a new surface plant is going in. The Western M. Co. is shipping 120 tons daily of milling ore and zinc, most of the material coming through the Adams shaft. They are also handling low-grade material, which is simply crushed before being shipped and is not handled by concentration.——The Midas M. Co., through its Midas and Coronado properties, is making an output of 250 tons a day and at the same time increasing development and prospecting work. The water is being handled for the combination at the Coronado, big pumps making from 800 to 850 gallons a minute.——At the A. Y. & Minnie group the mill is running steadily and receiving from the mine 80 to 90 tons a day, while 2000 tons a month is being shipped to the smelter.

The Oro shaft, on the west side of Carbonate hill, at Leadville, is down 320 feet and has crossed the Carbonate fault, and it is intended to sink the shaft down to the 600-foot mark, when drifting will be started to the northwest, where it is expected the ore shoot of the Carbonate mine will be opened.

La Plata County.

(Special Correspondenco).—The mining industry in the La Platas shows promise for the coming year. Work is progressing on the cyanide mill of the Bonnie Girl mine. They have their pipe line in place, ready for the power plant.

La Plata, Jan. 17.

Las Animas County.

Trinidad reports say the coal operators of Los Animas county are opening up the camps. Men are at work at Gray Creek, this being the first attempt to open this mine since the strike began. At Bowen the mine is on top of the mountain. The men at work have been furnished quarters at the mine, which has been provisioned, and on top of the hill overlooking the surrounding country is an electric searchlight, so that no one can approach the mine at night without discovery. The mines at Rouse are opening and there is a large number of men working at Hastings, Majestic and several of the other camps. The companies claim by Feb. 1st all the mines will be in full operation.

Ouray County.

Sixteen sacks of gold ore were shipped last week from the D. Lloyd mine, in Senator gulch, 4 miles from Ouray, in Mount Sneffels district, which assayed 100 ounces in gold and 37 ounces in silver. The strike was made by J. Genino et al., who have a lease on the mine. The ore streak is 8 inches in width and was cut after sinking 43 feet in an abandoned shaft 125 feet from the mouth of the tunnel. The tunnel is in 250 feet and they have 10 inches of ore in the breast that assays 10 ounces in gold and 10 ounces in silver. The property is owned by R. Porteus and C. J. Sigfrid of Ouray and I. Henry of Pueblo and D. Lloyd of Denver.

Park County.

(Special Correspondence).—The London Twist M. & M. Co., W. S. Smith manager, has a lease on the East London No. 2, Oliver Twist, Accommodation and Wapiti claims, which adjoin the London mine. They have a crosscut tunnel running lengthwise of the Accommodation for 600 feet and 200 feet on the Oliver Twist where it is said to cut the main London lodo. Work is being done with an electric drill. Ore has been struck. C. S. Card of Denver is president of the company.

The Moose mine, on Bross mountain, is under lease to J. Moynahan.——The Red Cross mine, in Buckskin gulch, has seven men at work. A German company has ninety days option on the Red Cross. The ore is of sulphides carrying 20% zinc and 17% lead.——The outlook for Park county for 1904 in the mining line is encouraging.

Alma, Jan. 18.

Saguache County.

The Citizens' Con. G. M. Co., of which V. A. Robinson of Florence is engineer and metallurgist, has been organized to operate, under a three years' lease and bond, the mines of the Villa Grove M. Co. They consist of four patented claims in Blake mining district. The company also has under lease and bond for one year, with right to buy, four mining properties in Cracker Creek mining district, Baker county, Or. The officers of the new company are A. F. Gasmire, C. A. Kalbitzer and T. H. Norton of Wheeling, W. Va. The company owns the Anna group of five claims near those of the Steel Canon M., M. & L. Co., operating near Villa Grove. The workings on the Anna group consist of a main tunnel on the vein a distance of 730 feet, and 500 tons of copper-silver ore has been taken out. The company's Oregon holdings consist of the Monarch, Mountain and Rockland Boy.

San Juan County.

H. Leo, F. Lewington and J. Gibbons have organized to operate mines near Silverton, under corporate name of The Solferino M. Co.

San Miguel County.

At the Butterfly-Terrible mine, near Telluride, thirty stamps (the full capacity of the mill) are dropping. Additions to the force of miners are being made daily.

Summit County.

At Kokomo the Breene mine will be in full operation next month, says the Summit County Journal. A new cable has been put on to the hoist. P. W. Breene is manager and superintendent.

The Raven and Eagle mines, near Kokomo, have been leased to R. Wiley, who is taking out ore.——The George Milo, a former producer, is being started up again. A large boiler and engine are being placed.

The North American M. Co., organized to operate in Ten Mile district, near Frisco, is arranging to begin work. This company has a group of claims on the western slope of Peak One, and its holdings extend from the Ten Mile river at the base of the mountain to its summit. A short distance above the river and the tracks of the South Park & Rio Grande railway the company has started a tunnel, which will be driven into Peak One a distance of 3000 feet, attaining depth of 3000 feet under the surface, cutting several veins from 5 feet to 20 feet in width. A plant of machinery will be put in, and the tunnel driven by air drills. A concentrating and cyanide mill will be added when the ore bodies have been sufficiently opened up. F. W. Howbert, E. C. Gard, C. D. Ford and F. B. Davis, of Denver, are interested. A. A. Miller of Grand Junction is manager.

The Gold Belt mine, at head of Mayflower gulch, near Kokomo, owned by D. Robertson et al. of Leadville, is in full operation and taking out gold-bearing quartz. P. J. Nelson is manager.

Teller County.

Superintendent Taylor, of the Old Gold and C. K. & N. mines, on Beacon hill, Cripple Creek, has twenty-six men at work on the Old Gold and fifty men on the C. K. & N., making fifty tons per day coming from the two mines. The ore averages two ounces gold per ton. The ore on the C. K. & N. is mined in a drift driven from the 275-foot level, while the ore on the Old Gold is being broken from a drift off the 350-foot level.

According to the record kept at the Mary McKinney mine, the water level in that part of the Cripple Creek district has been lowered 22 feet since the channel was cut by the drainage tunnel Sept. 6, 1903. This fall is said to be indicative of the result at the Elkton and others in the same section. The fall averages from 5 to 10 inches per week. Improvement has been noted at several other mines, but records are not kept. Less than 40 feet of water lies over the eighth level of the Elkton, while 20 or 30 feet covers the Mary McKinnoy's sixth level. Ore is opened and broken at this point in the Elkton, while the McKinney's shoot had not been reached when the flood interrupted. It is expected work may be resumed at this point before spring. No drainage is yet reported from mines at the eastern end of Bull hill. These include the Vindicator, Golden Cycle, Hull City and Findley.

Lessee Ellithorpe & Co., operating under lease the Big Banta mine, near Cripple Creek, propose putting in a plant of machinery over the shaft they are working to handle both water and ore.

Geologist F. L. Ransome and A. M. Rock of the United States Geological Survey have returned to Cripple Creek district from Washington, D. C., and will finish the survey of the district started last August. The topographical work has been completed, but before entering the large properties for the last part of the resurvey they were obliged to await the drainage of several mines which had not reached a point to permit them to descend to the levels they desired. W. Lindgren and L. C. Gretou will also assist

n the work. Every shaft 10 feet or more in depth is platted and every tunnel, road and shaft house in the district will be shown on the map.

There are fifteen sets of lessees operating on the Doctor-Jack Pot properties on Raven hill, Cripple Creek. During the month of December 500 tons of ore were shipped out by the lessees, which gave an average of $35 per ton. The entire production was made by eight sets of lessees, the remaining seven not shipping on account of development work.

The Parsons G. M. Co., which holds an option for $40,000 on three patented claims on southeast slope of Big Bull mountain, Cripple Creek, has opened up a body of ore in the breast of the tunnel which has been driven 325 feet. The ore shoot is 5 feet in width and assays show $10 per ton. The formation is oxidized and the company expects to put up a cyanide mill in the spring. They sank a shaft to depth of 100 feet and did some crosscutting, but were compelled to quit on account of the body of water encountered. The tunnel was then started.

The El Paso Gold King mine, up Poverty gulch on Womack hill, Cripple Creek, has resumed. The mine has been closed down since last July on account of water in the shaft. The shaft has been sunk to depth of 900 feet, but the water has so far receded, caused by the El Paso drainage tunnel, that the management considers work can be resumed in the lower levels.

The Aztec G. M. Co., operating on Mineral Hill, Cripple Creek, will resume operations on its Illk claim this week, after being closed down for thirty days. The suspension was caused by inadequate machinery, says Manager Conners, and he will put in an air compressor. The shaft has been sunk to depth of 235 feet, where a crosscut was started and driven west 40 feet. This crosscut will be extended to open the ore shoot found near the surface. The vein measured 5 feet in width. The company is composed of Chicago and Illinois men.

IDAHO.

Boise County.

F. B. Anderson, manager of the Black Pearl group, near Pearl, reports work on the Black Pearl progressing. A sbaft house, blacksmith shop and other buildings have been put up. Machinery consisting of a 22 H. P. gasoline hoist, Cornish pump, cars, track, etc., are being set up. Sinking is going ahead, with the shaft at 25 feet. Three hundred feet will be sunk before any crosscutting is done.

G. Stuck, operating the Mammoth mine, on Summit Flat, near Idaho City, is arranging to put in a 10-stamp mill. He reports a 6-inch shoot of high-grade ore in the Mammoth, struck on the 300-foot level, and by raising has been shown to continue to the 200-foot level. The ledge is 6 feet wide and carries gold.

Idaho County.

J. Keeth reports a strike on the Winifred claim, in which he is interested, on French gulch, ½ mile from the American Eagle mine, near Elk City. The Winifred is owned by A. B. Railton, J. Keeth and F. H. Harper. While doing assessment work, Keeth says they struck 1½ foot of gold-bearing quartz which assays $90. They have started a tunnel to tap the ledge at 100 feet in depth.

The Jumbo M. Co., at Buffalo Hump, is adding ten more stamps to its mill.

The power plant for the Crackerjack mine at Hump has been put up and the wire strung to the mine. The compressor is being set up. Crosscutting is being done on the lower level of the mine and 14 feet of milling ore has been opened.——The machinery of the Jumbo mine is on the ground.——Machinery for the Atlas is being set up. Raising and sinking is being done and the number of men is being increased. —— The Granite shaft is down 15 feet. A building has been put up over the shaft for protection.——Prospecting is completed on the Wide West and Gracie claims, and 12 feet of ore is reported opened up showing average of $12 per ton in gold.

Kootenai County.

A strike is reported made in the tunnel on the Richmond mine, near Tyson. A shaft was sunk 27 feet on the vein on the surface, where a fault occurred, and the vein lost. The tunnel has been run blind to prospect. The paystreak is 14 inches wide. The ore is oxidized and the gold free. H. W. Desgranges is president.

Shoshone County.

J. Keane, manager of the California group, near Wallace, says the production of the Galena mine for 1903 reached the value of $40,000. The mine shipped to the Globe smelter at Denver, Colo. Work on a part of the ground in the California group has been stopped by a suit pending.

W. S. Wilkinson of the Wild Rose mine, near Pierce City, last week sent out a cleau-up of $2500 from an eight days' run of the stamp mill. Wilkinson says the cyanide plant recently put in does not save as high a perceutage of the values in the tailings as was expected, and that the plant will have to be further improved.

At the Standard milling plant at Wallace in the Cœur d'Alenes, experiments are being made with three types of conceutrating tables for handling tailings that have been ground so finely as to slime, says the Spokesman. The Standard mill has been using canvas tables, but these have been proven unsatisfactory. The canvas plant would not save fine enough and subsequent treatment was necessary. At the Standard mill the middling product is treated by seven tables. It reaches the tables after it has passed through the jigs and the Huntington. It is the tailings from these tables that are being distributed to the three machines in the experiments.

Another reduction has been made by the railroads in freight charges on silver-lead ores from the Cœur d'Alenes, says the Spokesman-Review. The O. R. & N. and the Northern Pacific announce new rates to Perth Amboy, N. J., smelters. The O. R. & N. makes a straight rate of $12 per ton of 2000 pounds on silver-lead ore, carloads, minimum 30,000 pounds, "released to $50 valuation to Perth Amboy from Spokane, Burke, Mullan, Wallace and Wardner. The present rate from those points ranges from $13 to $17 per ton, according to valuation of the ore. Under the new tariff, ore which formerly cost $17 will be carried for $12, if the shipper is willing to release to a $50 valuation irrespective of the actual value of the ore. The Northern Pacific tariff is from the same points, except Spokane, and provides a $12 rate on ore "whose value does not exceed $60 per ton and released to that valuation." Higher grade ore, shipped via the Northern Pacific, will have to pay the former higher tariffs, unless the new tariff is amended by that road.

From the Hercules mine, near Wallace, about 850 tons per month are shipped, 750 tons of which go to Selby, the remainder being shipped to Pertb Amboy, N. J. The low-grade ores of the Hercules are not treated, as the company has no concentrator. During the past year 10,000 tons of ore were shipped, which averaged over $65 per ton.

Washington County.

P. H. Hamblin et al. of Chicago, Ill., are preparing to build a smelter of at least 500 tons capacity at Weiser. They will handle ores from eastern Oregon and from Idaho. Manager Hamblin will establish his offices at Portland, Or.

MICHIGAN.

The production of the Lake Superior copper mines in pounds of refined copper for 1903 is reported by the Michigan Gazette as follows:

Calumet & Hecla	76,500,000
Tamarack	13,000,000
Wolverine	9,150,000
Osceola	16,500,000
Mohawk	6,250,000
Franklin	4,900,000
Phœnix	180,000
Quincy	18,250,000
Isle Royale	3,100,000
Arcadian	170,000
Atlantic	5,500,000
Baltic	10,575,000
Trimountain	9,250,000
Champion	11,000,000
Winona	1,085,000
Mass	3,020,000
Adventure	2,235,000
Michigan	245,000
Total	191,000,000

The output in pounds for tbe four years preceding was: 1899, 146,000,000; 1900, 142,051,000; 1901, 155,618,848, and 1902, 172,020,065.

Houghton County.

The Copper Range Con. C. Co. is preparing to carry mineral from the South Range mines to its smelter in especially constructed steel cars, doing away with the necessity of barreling the mineral, says the News. This will effect a saving in the milling expenses, as only the heaviest of oak barrels can be used. The Dollar Bay smelters are shipping refined copper East as fast as smelted. There has been no accumulation on the docks as yet. ——Permanent hoists at No. 2 and No. 3 shafts of the Trimountain mine of tbe Copper Range Co. will be ready by Feb. 1, when the six-ton skips will go on, increasing the rock supply for the mill. Their Baltic rock is said to be running heavy in copper at present. An additional wash flow is being arranged at the Baltic mill similar to that in operation at the Mohawk and Wolverine mills.

No. 3 Tamarack mine hoist, near Calumet, is being rushed in order to make up the time lost by the delay caused by the fire. On the 13tb inst. 1400 tons were hoisted. The January showing of the Tamarack is expected to be up to the average production, notwithstanding the few days' delay.

The management of the Isle Royale mine, near Houghton, is working seventeen drills in No. 2 shaft, keeping one head in the mill supplied. All but three of these drills are stoping.

Keweenaw County.

Tbe Miskwabik mine, near Allouez, is cutting a plat 125 feet from the old surface in the shaft on the Kearsarge lode. The company will drift north and south to determine whether the lode holds its character, says Superintendent Robson.

MONTANA.

Estimates place Montana's mineral production for 1903 as follows: Copper, $25,000,000; silver, $6,000,000; gold, $4,000,000; lead, $1,000,000: total, $36,000,000. The year, despite several shutdowns, has been a notable one in the bistory of mining in Montana. There will, because of the two shutdowns of the Amalgamated Co. properties, be a falling off in the production of copper and silver (silver being mined chiefly as a by-product of Butte copper ores), but an increase in the gold output is shown, the estimate for this metal being $2,086,359, against $1,793,232 in 1902. For this several reasons are given, chiefly the adaptability of recent discoveries to treatment by cyanide process, the increased value of silver and lead and cheap power from the Missouri dam. Fergus county has shown the largest increase, through building of cyanide plants, and this county in 1903 shipped $975,000 in gold bullion. For the first time in its history, Montana during 1903 exported both coal and coke, Wyoming and British Columbia being the buyers. A strike of coal was made in the Bear Creek fields, in Carbon county. This field is owned largely by the Northern Pacific, the Amalgamated C. Co. and a company with E. Smith et al. of Boston, Mass. A railroad will be built to the district in the spring from Red Lodge, a distance of 16 miles. Contracts were let in Decemlier for building the Basin & Elliston Railroad, which will tap several districts heretofore unavailable because of lack of transportation. This line will connect the Northern Pacific and Great Northern lines, placing both Butte and Helena smelters in direct communication with these mines.

NEVADA.

Lincoln County.

A strike of gold ore is reported made 12 miles nortbeast of Searchlight, on ground owned by H. Perkins, E. Thurman and G. Duncan. It is three-fourths of a mile north of Dupont mountain. The ore is free-milling.

The Cyrus Noble mine, at Searchlight, resumed operations last week after a temporary shut-down. At 100 feet west of the sbaft, on the 200-foot level, a winze has been started to connect with the lower level. It is being sunk on a shoot of ore. Other work under way is continuing of the west drift on the 300-foot level. It is expected the incline will not be put down much deeper, but a vertical working shaft will be sunk.

Development work is being done on the Black Bear mine, at Searchlight, owned by R. H. McElwain. This claim adjoins the Quartette group on the west end.

The New Era M. Co., at Searchlight, reports, on account of non-arrival of material for the mill and pipe line, the company has suspended operations temporarily.

White Pine County.

D. N. Harper has bought a group of forty claims on tbe mineral belt, adjoining the New York & Nevada C. Co. and White Pine C. Co. He is arranging to put in machinery for developing his holdings. The first work will he done on the Elkhorn and Sunset group. Surveys of the entire group will be made.

NEW MEXICO.

Grant County.

High-grade gold ore is being taken out of the Owl mine at Gold Gulch, says the New Mexican. On the Tbompson & Copp lease a strike is also reported. The sinking of the other shafts to greater depth drained the Hamilton shaft and an examination of the old stope showed ore remaining. Two veins showed the length of the stope 40 feet, and also in the face of the drift.

Luna County.

The Othello mine, at Cooks, is shipping ore.

Sierra County.

The tunnel being run on the Mamie Richmond mine, at Hillsboro, to connect with the 200-foot level, has developed a breast of sulphide ore 4½ feet wide, says the New Mexican, and 100 tons of ore has been taken out. Sixty tons of the ore assayed $30 per ton, the balance $18 per ton.

Socorro County.

The Santa Fe Enterprise M. Co. has been incorporated by C. K. Minor, G. A Freeman and E. J. Plumley of Buffalo, N. Y., with principal place of business at Cooney, Socorro county.

OREGON.

Baker County.

The Don Juan mine, near Greenhorn, has been closed down again, says T. W. Davidson, of Davidson & Brown, who were operating it under bond.

Regular shipments of ten tons daily of concentrates are being made from the Baisley-Elkhorn mine, near Baker City. The plant consists of two Huntington mills and concentrating tables.

The high-grade copper ore struck in the lower workings of the Copperopolis mine, near Sumpter, is not of the main copper shoot of the surface croppings, but a smaller fissure, which carries about 3½ feet of bornite, says Manager W. W. Gibbs. In the main adit a diagonal crosscut will be driven in a direction that will open the main vein and also this bornite shoot at another point. The ores of both veins will be concentrated. On another claim of the group which is being worked a copper-bearing vein 8 feet wide has been opened. Concentrating it ten into one a product of 40% copper is obtained.

Clackamas County.

The Molalla Central M. Co., operating in the Cascades, near Molalla, is preparing to put up a milling plant in the spring. A road will be built to the mine.

Douglas County.

A. D. Le Roy, manager of the Le Roy mine, at Bohemia, says work continues and development done is encouraging. The body of ore in the lower tunnel shows 48 feet wide and is of concentrating grade. On tunnel No. 3 they have opened a body of free milling ore 9 feet wide, with a shoot carrying sulphides. It is intended to build a concentrator this season.

Grant County.

Drifting work is in progress on tbe placer deposits of G. W. Dart, near Prairie City, says the Prairie City Miner. He is driving a tunnel to prospect the deposit. The gravel being removed is said to pay for the work, altbough the drift is but 40 feet long. The work will continue during tbe winter.

Josephine County.

W. J. Morphy of Chicago, Ill., manager of the American Gold Fields Co., owner of the Granite Hill mines, near Grant's Pass, says machinery is on the ground for mill and power plant. The compressor will be ready for operation by February 1.

UTAH.

Juab County.

B. L. Cutler, superintendent of the St. George C. Co. at Dugway, east of Fish Springs, says the camp is improving. High-grade copper ore, whicb also carries values in gold and silver, is being taken out. Tbe St. George mines are owned by W. F. Snyder, C. McCornick, B. L. Cutler, E. J. Raddatz et al., and the miners are drifting from the 100-foot level and have cut a body of lead ore 200 feet from the chute, some of which is now being taken out for shipment. The group also shows surface ore running 20% copper, $40 gold and twelve ounces silver, says Cutler. He is also superintending work on claims of the Dugway M. Co., of which A. M. Cannon is president. The Dugway has 29½ patented claims and is working a few men on the Black Maria, on which tbe shaft has been sunk to depth of 50 feet, with a crosscut of 51½ feet. The ledge was cut at depth of 20 feet, and they sacked five tons of ore, showing values in copper, gold, silver and lead. They are crosscutting for the contact.

In tbe Endline claim, on same group, there is a vein 28 feet wide at depth of 60 feet, where a whim has been set up. The Rattler group of fourteen claims shows a body of lead ore 2 feet thick in the vein.

Pinte County.

G. T. Wilson, owner of the May Day group in Ten Mile district, near Marysvale, says the May Day group consists of five claims, and the principal values are in copper. The main tunnel is in 170 feet and running in quartz all the way.

Salt Lake County.

The aerial tramway of the United States M. Co. at Bingham is transporting 850 tons of ore per day from its mines to the smelter, says Superintendent Mayberry.

The Farmington Con. Oil & Gas Co. has been incorporated at Salt Lake City by S. V. Shelp, C. K. Rowland, H. Satterlee, G. T. Odell, E. B. Jones and A. C. Ewing. The holdings of the company consist of 16,000 acres adjoining the Guffey-Galey tract near Farmington.

Superintendent W. G. Scott of the Continental-Alta mines, at Alta, reports completion of clearing the old tunnel to tbe Lavinia stope, which was formerly one of the productive parts of the Lavinia mine, now owned by the Continental-Alta. This tunnel has been closed, on account of the

cave-in, for twelve years. There is still considerable ore left in this stope, and it is intention of Manager H. M. Crowther to ship, and also to make further explorations there. In the meantimo shipments will continue from other portions of the mine, while the good roads last, before the spring thaws come. Difficulty has been experienced in securing teams.

Summit County.

It is reported that work will resumo at the Glencoe mine in Blue Ledge section, near Park City.

The forces at tho Park City Majestic property are soon to be increased, according to the advices from that camp. Michigan parties have become interested in the mine recently.

Work has been suspended for tho winter at the Hi Henry property at Park City.

The American Flag Co., operating at Park City, is laying a pipe line to increase its water supply.

Tooele County.

The Sacramento M. Co., at Mercur, in 1903, produced gold bullion for which it received $115,122.14, and retorted quicksilver that netted $16,422.82, according to tho annual report. The tonnage of oro blocked out will afford supply during tho present year both for tho cyanide plant and for the mercury retorts. During samo period the company distributed among those employed at the mines and plants $40,519.09: for explosives, etc., $37,934.97. G. R. Bothwell is president and manager.

SOUTH DAKOTA.

Lawrence County.

The Big Four M. Co. will rebuild its hoisting plant, near Deadwood, which was destroyed by fire last week. Such of the machinery as was only partly damaged by tho fire is being overhauled. The company's mine is in the phonolite belt.

WASHINGTON.

Chehalis County.

W. J. Shaw of Cincinnati, Ohio, says the black sands (magnetite sands) at Damon's Point, on north side of entrance to Gray's Harbor, are capable of conversion into iron ore. The Beach Placer M. Co. has been incorporated with Shaw as president and manager. He has a lease from the owner of the land on 500 acres for twenty-five years. It is proposed to put in a reduction plant at a cost of $10,000. The smelter will be half a mile from deep water, making shipping easy, and the adjacent forests will furnish fuel.

Ferry County.

(Special Correspondence).—During 1903 the ores mined here were treated at the Tacoma, Nelson, Trail, Boundary Falls and Crofton smelters. These smelters have ceased to take ore, but another smelter is now taking ore from the Quilp, Mountain Lion and Knob Hill mines. The Quilp continues shipping sixty tons daily.

The Hendrycks new cyaniding process will shortly be in use at the Mountain Lion mine. The value of the new process will be known within a few months.

Tho lower tunnel at the Knob Hill will soon reach the vein. A raise is being made from the upper tunnel to connect with a shaft. When completed, the mine will be thoroughly ventilated, which will enable ore to be stoped in many places. ——It will be some months before the Bodie mill at Bodie is ready to treat the ore.

Republic, Jan. 16.

A strike is reported at the Vesuvius claim in tho Malachite group, near Keller, owned by the Lorraine C. M. Co. In driving an open cut on a vein cropping they struck a body of arsenical-iron ore, carrying gold values. They have a 12-foot face of ore above tho floor of the cut, and they are sinking in the same material. On top the vein shows quartz, and the iron is oxidized, but in the cut and in the shaft the material is arsenopyrite, says the Review.

Okanogan County.

A 5-foot ledge has been struck in tho drift to the right of the main tunnel in the Mineral Hill mine, 2 miles west of Conconully, says the Review. The ledge carries an 18-inch shoot with ruby silver, and 150 feet of this vein has been exposed. The work is being continued with the intention of taking out no ore until spring opens, when shipping will be started. Work on the main tunnel, which is 1100 feet long, will be resumed as soon as an air compressor plant can be put in.

The Salmon River M. & M. Co. miue, on Peacock mountain, south of Conconully, is being worked. A. L. Boswell has a contract for driving the tunnel 400 feet farther and has sixteen men at work. T. Jamos of Spokane is manager.

Work has been temporarily suspended on the Q. S. mine, near Conconully, owing to bad air in the tunnel. S. Barron, manager, expects to put in an air compressor plant this month, when work will be resumed.——H. A. Wilder has a contract for cutting a 200-foot crossent tunnel ou tho Northland mine, near Blue lake. ——Work on the Copperhead mine of the Blue Lake M Co. is going ahead.

Stevens County.

(Special Correspondence). — The diamond drill at the Little Giant mine, in Pierre Lake district, has been replaced by an air drill and a permanent shaft will be sunk near tho last borings, which showed gold and copper ore.

Work has been resumed on the Great Columbia mine, 3 miles north of Bossburg, on the Colville Indian reservation. The Great Columbia vein contains 18 inches of zinc ore which averages 48% zinc. A tunnel is being driven to cut the vein at depth of 150 feet.

The Boston Climax Co., of Providence, R. I., has begun operations on its group on Towlow mountain in Pierro Lake district. The tuunel, which is in 500 feet, will be continued until tho main lode is opened up. The Boston Climax ore carries gold, copper and nickel values.

Mulligan Bros. havo opened up high-grado homatite in the Pittsburg mine on O'Toolo mountain.——J. Dolan is developing the Monarch group opposite Bossburg. A shaft is being sunk.

Bossburg, Jan. 17.

WYOMING.

State Geologist Beeler has issued the following figures for copper product on of Wyoming:

1882	$18,757 50
1883	131,858 11
1888	36,017 32
1889	12,000 00
1897	14,015 28
1898	27,965 28
1899	530,925 39
1900	683,601 50
1901	140,909 82
1903	127.101 62

FOREIGN.

AFRICA.

Transvaal.

The Windsor G. M. Co., near Johannesburg, reports crushing began Dec. 31, with 45 stamps, on ore taken from the mine and from the dump. As less than half the full complement of native labor is available, it will not he possible until supply is increased for the mill to be kept on ore taken from the mine only.

AUSTRALIA.

New South Wales.

The Broken Hill Proprietary Co., at Broken Hill output for four weeks ending Dec. 30 (including product from ores purchased) was: Refinery products, fino silver, 300,044 ounces; soft lead, 5210 tons; antimonial lead (estimated), 52 tons.—— The Mount Boppy G. M. Co., under date of Dec. 26, reports level No. 3 (new ore body) is in 120 feet, giving assays of 8 dwts. gold per ton. The reef, 100 feet in, shows 42 feet wide, worth 11 dwts. per ton.

Queensland.

Tho Day Dawn Block & Wyndham G. M. Co. at Charters Towers roports returns for five weeks ended Dec. 24, as follows: From the battery, 3350 tons of ore crushed for yield of 2611 ounces of gold (including the annual clean-up of plates), valued at £9100. From the company's cyanide works at Burdekin River and Old Wyndham mills, 4996 tons of tailings were handled, yielding hullion valued at £3700.

Western Australia.

In the Kalgurli mine at Kalgoorlie, the ore body has been opened up for continuous length of 320 feet at the 1000-foot level, the ore met with in driving averaging an ounce of fine gold per ton for a width of 30 feet. Telluride ore is showing in the north face, apart from the specimen stone assaying two ounces per ton. No work had been done on this lode prior to it being tapped last fall by a crosscut at a point 100 feet west of the main shaft, says the Western Australia Journal. The Kalgurli's west lode is yielding sulphotelluride ore for a length of 206 feet in the stope above the 200-foot level. F. H. Moss is manager.

A specimen of gold-bearing asbestos is reported taken from a seam struck at depth of 200 feet at Kunanalling.

The gold export and mint returns of Western Australia are reported as:

	Quantity Ounces Exported.	Received at Perth (W.A.) Mint. Ounces.	Total Ounces.
January	101,594	108,857	210,451
February	80,250	112,148	192,398
March	78,907	115,816	194,723
April	86,987	121,640	208,627
May	92,779	114,722	207,501
June	72,278	135,781	208,059
July	90,176	122,325	212,501
August	82,265	134,352	206,617
September	71,581	129,824	201,405
October	72,494	118,291	190,785
November	75,775	125,399	201,174
December	78,599	123,471	202,070
Total			2,436,311

The total ounces for 1902 amounted to 2,177,441.

At Kanowna, in northeast Coolgardie section, diamond drilling is under way at the bottom of the Government shaft on the Deep Leads mine to test the alluvial deposits. —— The public mills are in full operation, most of tho ore handled being low grade.

Victoria.

(Special Correspondence). — Bewick, Moreing & Co., large operators in Western Australia, are going to sink several test bore holes in Victoria gold fields where they have acquired some interests, where H. C. Hoover and W. Lindgren recently made examinations.

Melbourne, Dec. 20.

BRITISH COLUMBIA.

Cassiar District.

Work on the Princess Royal G. & C. M. Co.'s mines, which has been temporarily suspended, will be resumed this week. The shaft, which was sunk to 35 feet last year, will be lowered 50 feet farther, says H. W. Parrott at Bellingham, treasurer of the company. It is expected the ore body will be cut at a depth of 65 feet. This property consists of four full claims on Princess Royal island, on the inside steamship passage to Alaska. The shaft is close to tidewater, which eliminates the expense of a tramway. Water power is said to be available sufficient for all needs. The ore carries gold and copper values.

Nelson District.

(Special Correspondence). — After a close-down of five years the Dundee mine of the Ymir camp will be reopened. The company has three shifts at work pumping out the mine, which is expected to be finished next week. Development work will he increased and shipments started. When the snow goes off in the spring, further opening up the mine by means of a long tunnel will be started, as the present methods entail heavy expense in pumping and hoisting.

Second payment of $3500 on the Gold Cup group has been made by J. F. Davault. The Gold Cup group consists of three claims 4 miles north of Ymir and 1 mile east of the Great Northern railway. A 2-stamp mill has been built beside the line of railway and the rawhiding of ore will be started this week from the 500 tons of ore on the dump. Since July 8, 1903, 475 feet of work has been done. A shaft has been sunk 125 feet and a tunnel driven to connect at depth of 255 feet. The ore shows values in gold, copper and silver.

Nelson, Jan. 16.

Rossland District.

Regarding the ore strike in the lower levels of Le Roi mine at Rossland, Manager S. F. Parrish says at a point 300 feet west of the main shaft, on the 1350-foot level, a crosscut has been run 100 feet along the course of the diamond drilling. Since striking the ore body, he has drifted 50 feet one way and 30 feet another, showing the shoot the full length. Muck samples run $12 to $20 per ton. At a point farther west another crosscut on the same level has also opened ore of similar grade to that found nearor the shaft. It is not known if this is a continuation of the first strike. The new shoot is on the south side of the mine. The work on it at present consists of crosscutting and drifting. A winze will he sunk and raising will also be done.

Slocan District.

The electric hoist at the Payne mine has been set up, replacing the hoist in No. 5 tunnol, which will be transferred to No. 8.——The Province Mines, Ltd., is shipping ore from South Fork.——Fifteen men are at work at the Hewitt mine. A body of ore was struck in the upper works last week and shipments will be resumed before Feb. 1st. In the lower levels the Hewitt has bodies of concentrating ore blocked out, for which a mill will he built.——It is expected the Galena Farm mine will again he worked. Five hundred tons of ore will be run through the Wakefield mill, and if satisfactory results are obtained, the property will be worked regularly.

The Monitor mine, at Three Forks, on the line of the Canadian Pacific railroad, shipped 800 tons of galena during 1903 and has worked twenty men. Considerable development work has been done and it is expected the company will build a treatment plant next summer to handle the low-grade and zinc ores. The ore carries $8 per ton in gold, silver and lead. The property is owned by an English company, with M. Gintzburger manager.

The Rambler-Cariboo mine, near McGuigan, has been working an average of sixty-five men and shipped 1500 tons of galena bearing ore and concentrates during 1903. The concentrator worked steadily from June to the middle of November, when it closed for shortago of water. A flume was built and the compressor moved down the hill. The plant will he run by water power, and will furnish power and air for the mine, doing away with hauling of coal. The mill will start again in the spring to treat the dumps. A tunnel of 4000 feet will be started this month to tap the shoot at depth.

West Kootenay District.

(Special Correspondence). — For the month of December the Eva mill of the Calumet & British Columbia G. M. Ltd., 2 miles from Camborne, crushed 830 tons of ore during 28½ days, the result being five bars of bullion aggregating 715 ounces, valued at $11,000 and fifteen tons of concentrates worth $330. The average value of the tailings was $1.40 per ton. The ore runs $14.50 per ton.

Finch & Campbell of Spokane, Wash., have bought the Buffalo Group, 3 miles southeast of Poplar. It consists of two claims. The property is 200 yards from the Canadian Pacific railway on east side of Cascade creek.

Camborne, Jan. 16.

Vancouver Island.

The Lenora mine, at Mount Sicker, owned by Breen & Bellinger of Spokane, Wash., reports a strike in the lower workings. Under Manager Tregear, work had been proceeding in the old workings. Both in the Lonora and the Tyee the ore has been found up to the present, says the Telegram, along the diorito wall which cuts both properties. Tregear worked away from this in a northerly direction, running 100 feet, when the new body was cut, showing 9 feet of copper ore.——The Crofton smeltor, of which the Spokane, Wash., men are owners, has been blown in again, and the Richard III mine, at top of Mount Sicker, above the Tyee, is shipping ore to the smeltor at the rate of fifty tons a day.

CANADA.

United States Consul M. J. Burke of St. Thomas reports the output of metalliferous mines and works in Ontario for first nine months of 1903 as follows:

Mineral.	Quantity.	Value.
Gold, ounces	7,693	$139,210
Silver, ounces	19,549	10,124
Iron ore, tons	262,403	376,103
Pig iron, tons	56,783	1,051,940
Nickel, tons	5,393	2,115,957
Copper, tons	1,320	330,263
Zinc ore, tons	950	7,600
Total		$4,031,197

On this basis, it is expected the output of the province for the entire year will reach the value of $5,300,000.

Yukon Territory.

Dawson reports say a cold wave struck Dawson last week. For forty-eight hours the thermometer registered 50° below zero, going as low as 59°. On Lower Le Barge, the coldest point on the river, it was 67° below. "Lays" are being let on El Dorado creek for second hedrock only, and good pay is found. It is thought tho second bedrock extends the full length of the creek, and will produce as much gold as did the first or "false bedrock." On No. 3 a second bedrock was located at 75 feet, producing as high as $25 a pan. Pay has been located under Grand Forks townsite. Several parties are sinking shafts in their back yards.

CHILE.

The Copiapo M. Co., at Copiapo, on December 28, reports a fire occurred in Fletcher's shaft at the Dulcinea mine. The mine has been tightly closed, but it has not been possible to ascertain amount of damage done. It is thought that below the 100-fathom level (600 feet) the damage has not been serious.

COLOMBIA.

The Darien G. M. Co., at Cana, under date of Dec. 20, reports mill stopped on account of political uneasiness, but operations in the mine continue. The American staff is temporarily in Panama.

MEXICO.

Chihuahua.

Work is expected to begin next month on the proposed wagon road from the end of the Parral & Durango Railroad to Guadalupe y Calvo. Engineer L. W. Knotts, appointed to select a route, reports one practicable at a cost of $60,000. The State and Federal government will raise two-thirds of the money and the rest from private subscription. The road will open up several mining camps, including the Piedra Largo, San Julian, Cueva Colorado, Gallina, El Cuerva, Dolores, San Simon, Cumbre de Sau Manuel, San Juan, Neponucino, Milpillas, Baborigame and others. A telephone line will also he put up along the road.—— J. M. Botello of Parral has arranged to start the Parral M. Co.'s mill Feb. 1. The deal of J. Leiter et al. for the Hidalgo M. Co.'s property being off, that compauy will start its mill next month.

A. C. Aiken of San Francisco, Cal., who

has the San Juan mine and the Democracia, at Santa Eulalia, has two diamond drills at work, one operated hy steam on the Democracia. The other, a hand drill, hut which will be operated hy gasoline engine, is underground on the San Juan. The Southern M. Dev. Co. has been organized to operate the Democracia group with H. F. and P. Robinson of Akron, Obio, interested with Mr. Aiken et al. of San Francisco, Cal.

The Palmarejo & Mexican Goldfields, Ltd., T. Southcott of London, president, reports work progressing on La Patria mine of the company. He says thero are 10,000 tons of ore at this and the Esperanza mines blocked out. The company expects to find the vein in the La Patria in the Paneha tunnel, which is 360 feet below tunnel No. 2. A mill of fifteen stamps will be put up. The approach of the railroad to the company's holdings has made it possihle for machinery to be transported there, in which case the ore will not have to be shipped to Zapote, where it is now treated. The company owns a total of 105 acres.

Guadalajara.

It is stated the United Mexican M. & S. Co. will huild a furnace to smelt the quicksilver ores from its mines at Mascota.

Jalisco.

The Tulu Iron Co. reports it can produce iron hy using charcoal instead of coke for $7.08, as against $10 in the United States. The company's property is on the Zopotlan hranch of the Mexican Central and in the Sierra Madre mountains, south of Guadalajara. Timber for charcoal and other purposes is ahundant and at hand. Water power is convenient. The mill is composed of a 25-ton charcoal blast furnace, a foundry with two 5-ton cupolas, cranes, a rolling mill, trams or tolls, puddling furnaces, machine shop, pattern shop, sawmill, etc. There are 500 men employed on the property.

A company is exploiting the La Estrella mine, in the Sierra de la Una de Gato, near Zaposlan. It is said to carry native silver.

Michoacan.

At Tlalpujahua the Dos Estrellas cyanide plant consists of six 60-ton steel preliminary sand-treatment tanks, six 120-ton steel sand-leaching tanks, eigbt 28x 18x8 feet masonry-slimes agitation tanks, eight steel slimes-washing tauks 20 feet in diameter and 10 feet deep, and tbree 30x 40x5 feet masonry storage aud sump tanks. Owing to greater tonnage per stamp of the new 80-stamp mill, says the Mexican Investor, the equipment will he increased by addition of eight steel tanks each 20 feet in diameter and 10 feet deep.

At the Jupiter mine at Tlalpujahua, at a depth of 120 feet in the three-compartment vertical shaft, so much water was met with that sinking operations were suspended. Another sinking pump is being set up, after which it is thought that sinking operations can be resumed. Two 60 H. P. boilors and a double hoist will he put in.

At Tlalpujahua the equipment of the San Rafael mill of tho Luz de Borda Co., which is locatod 3 kilometers north from the main shaft of the Luz de Borda mine, consists of fifteen stamps, 3 plates or tables, settling tanks, six concentrating tables, oue Krupp barrel mill with capacity for crushing twenty-five tons of ore per day, one engine, three boilers, crushers, etc. The stamps and the Krupp mill are treating 1500 tons of ore per month, which is said to run 16 ounces silver and 2 ounces gold per ton. About 100 tons of shipping ore is also heing mined each month, which is said to run 160 ounces silver and 3.2 ounces gold per ton. All ore from the workings is brought to the mill on backs of burros, hut the company proposes putting up a wire-rope tramway.

Nuevo Leon.

The Monterey News says the tunnel which has been under construction for the past ten years in Catorce district for draining the mines, will be completed by April 1st. The tunnel was originally the Socavan de Cuadalupe mine. It is 2 miles long and will end beneath the Concepcion, Padre Flores, Trompeta, Santa and San Augustine mines. The driving has all beeu done by hand, but an air compressor and drills are uow in operation. The tunnel is owned by the Padre Flores M. Co., owning the Padre Flores mine.

Sonora.

The Sonora G. M. Co. has been organized to work gold placer properties near Alamos. R. D. Hugbey, of Alamo, is manager, and C. Butterfield, of Denver, Colo., is president. The company will put in machinery, including centrifugal pumps.

The Los Licenciados mine, a mile south of Santa Rosa, is reported sold to tho Colorado A. & R. Co., of Denver, Colo., for $5000 gold. Tbe ores carry gold and silver.

M. P. Wright et al. have bought Los Amigos (formerly the Realito) group of antigua gold mines near Ures, east from Minas Prietas, and will increase development. The property includes twenty pertenencias, having a gold-hearing ledge 14 feet wide. Along the ledge are tajos (open cuts), from which rich ore was formerly taken and reduced in arrastras. The new owners will go helow the old workings and open up the ore hodies. Development will be followed hy a mill. Wright has denounced forty-eight additional pertenencias of mining ground adjoining the group.

At the Wandering Jew mine, in Tyndall district, Santa Rita mountains, Superintendent M. Lulley has men driving development on the ore body.

Tamaulipas.

The Mexican Petroleum Co., with wells at Ebano, near Tampico, will hegin huilding a refinery next week.

Personal.

W. M. KEENAN, Denver, Colo., is in Le Roi, Illinois.

JNO. E. MCMANUS, of Seattle, Wasb., has gone to Mexico.

P. ARGALL, of Denver, Colo., is in Mexico ou mining husiness.

W. T. HUPP, of Folsom, Cal., is in San Francisco, Cal., on mining husiness.

J. J. BROWN of Leadville, Colo., is examining mines in La Plata county, Colo.

C. K. COLVIN, of Denvor, Colo., has returned there from a trip to Globe, Arizona.

T. J. LYNCH, of Reno, Nev., is in San Francisco, Cal., from Nye county, Nev., mines.

MANAGER PROCTOR of the Darien M. Co. at Cana, Colombia, is at Panama, South America.

ALGERNON DEL MAR of Pine Grove, Nev., has gone to Los Angeles, Cal., on mining husiness.

N. B. KNOX has returned to San Francisco, Cal., from an inspection of mines at Cananea, Mexico.

CHAS. STEELE, millman, has gone from Mariposa, Cal., to the Oriental Con. M. Co., Chemulpo, Korea.

J. W. VAN METER has returned to San Francisco, Cal., from a successful husiness trip to Los Angeles, Cal.

D. C. TOBIN, superintendent of the N. A. P. & M. A. Co., White Pine, Colo., has returned there from Denver.

W. L. WATTS of Los Angeles, Cal., is in tbe State of Mexico, Mexico, where he is investigating mining property.

L. WYMAN, assayer for the Wyman M. Co. at San Javier, Sonora, Mex., returned there last week from a visit to Obio.

S. M. MILLER, manager of the Akron M. Co., has returned to White Pine, Colo., from an Eastern husiness trip.

B. B. THAYER, late manager of the Santa Rita (Mexico) M. Co., has opened a professional office in New York City.

A. E. DRUCKER, recently returned from Minas del Tajo, in Sinaloa, Mexico, is in San Francisco, Cal., from Washington.

F. H. MOSS, manager of the Kalgurli mine at Kalgoorlie, Western Australia, is in London, England, on company husiness.

NORRIS ENGLISH, consulting engineer of the Mt. Jefferson Co., has returned from Groveland, Cal., to San Francisco, Cal.

D. G. FORBES has resigned as local manager of the Nettie L. and the Silver Cup mines at Ferguson, in the Kootenays, B. C.

A. R. WILFLEY has returned to Denver, Colo., from Idaho and Montana, where he has been looking after mining interests.

J. G. HARDY has resigned as superinteudent of the Crestou-Colorada M. Co., operating at Sonora, Mox., and is in Denver, Colo.

J. K. BURCH, superintendent of the Abbott quicksilver mine in Lake county, near Sulphur Creek, Cal., is in San Francisco, Cal.

R. K. HUMPHREY, former superintendent of the California G. K. M. Co. of Picacho, Cal., has resigned and gone to Oklahoma.

S. TURNER, superintoudent of the Calumet & Bisbee and the Calumet & Cochise mines, near Bisbee, Ariz., has accepted the superintendoncy of the Higgins Dev. Co., vice S. A. Parnall, resigned, to accept tbe superintendency of the Calumet & Arizona.

PRESIDENT GILL of the Shannon C. Co. and President Ross of the Standard Con. C. Co. are in Boston, Mass., from Clifton, Ariz.

C. W. PHILLIPS of the Rey de Oro M. Co., operating near Magdalena, Sonora, Mexico, is in Cbicago, Ill., on company husiness.

H. A. TITCOMB, witb the Guggenheim Exploration Co. of Denver, Colo., is in Salt Lake City, Utah, having estahlished headquarters there.

V. P. STRANGE of the Balaklala M. Co., operating at Kennett, Shasta county, Cal., returned to Salt Lake City, Utah, last week from California.

P. H. HAMBLIN, of Chicago, Ill., manager of the smelter company which will huild at Weiser, Idaho, will move his offices to Portland, Or.

H. I. WILLEY has resigned as chief engineer for the Yaqui C. Co., operating at Campo Santo Nino, Sonora, Mexico, and is at Hermosillo, Sonora.

C. R. DOWNS of Sutter Creek, Cal., superintendent of the Bunker Hill mine, near Amador City, is in San Francisco, Cal., on mining husiness.

J. H. MORELAND, formerly superintendent of the Eureka Exploration Co., Eureka, Colo., has purchased an assay office in Kansas City, Mo.

H. C. HOOVER of the mining firm of Bewick, Moreing & Co. of London, England, has gone from San Francisco, Cal., to London, via New York.

G. WYMAN, president of tho Wyman M. Co., returned to San Javier, Sonora, Mex., last week from a husiness trip to Guaymas and Hermosillo, Mex.

H. M. DEAVITT, analytical and consulting chemist and assayer, is manager of the Chicago office of the Engineering Co. of America, 159 La Salle street.

A. J. BRENT has roturned to San Francisco, Cal., from New River district, Trinity county, Cal., where be is interested in tbe development of a gold mine.

J. A. CZIZEK, manager of the Lost Packer mine in Custer county, Idaho, has returned to Salt Lake City, Utah, from San Francisco, Cal., and Portland, Or.

L. COCHRANE, who has charge of the assay department of the Mine & Smelter Supply Co., Denver, Colo., is making a trip through Mexico in the interest of the company.

G. W. MYERS, of San Francisco, Cal., has gone to the mines of southern California and western Arizona in the interest of the Chrome Steel Works of Brooklyn, N. Y.

BARON C. VON REISCHACH, mining and metallurgical engineer, interested in Mexican mines, starts from San Francisco, Cal., for Europe to-day to be absent for an indofinite time.

F. L. RODEBUSCH of London, England, and G. L. Fisher of Denver, Colo., interested in Mexican mines, are in the State of Sinaloa, Mexico, from Hermosillo and Minas Prietas, Sonora.

C. R. TOWNSEND has resigned as superintendent of the California mine, near Sumpter, Or., and will take charge of development of the Gold Hill mine at Gold Hill, Jackson county, Or.

H. E. WEST, recently manager of the Pacific Northwest M. Co., Ltd., operating in Montana, is superintendent of the Leonesa M. Co. at Matagalpa, Nicaragua, C. A., operating gold mines in Nicaragua.

M. P. PARKER AND J. K. FRIEND, of El Paso, Texas, returned there last week from the Placer de Guadalupe. on the Conchos river, in Chihuahua, Mexico, where they havo been examining mines.

J. TONKIN, for several years underground superintendent at the Hecla branch of the Calumet & Hecla mines at Calumet, Mich., has resigned, and will be succeeded by Assistant Superintendent Richards.

W. P. HARLOW has resigned as president of the Yaqui C. Co. at Campo Santo Nino, Sonora, Mex., being succeeded by W. Sauntry, formerly vice-president. C. Kaiser, assistant general manager, has also retired.

J. M. HILLYER has recently been engaged in examining some mining properties adjoining the La Yesca mines on the Bolanos river in tho State of Jalisco, Mexico, for J. M. Rhodes, an English mining investor.

W. E. POMEROY, until recently general superintendent of the Yaqui C. Co. at Campo Santo Nino, Sonora, Mex., has been appointed general manager. Mr. Pomoroy returned to the mines last week from a visit to Mesa, Ariz.

PHILIP ARGALL of Denver, Colo., has heen unanimously awarded by the Institution of Mining and Metallurgy of London the gold medal and 40 guineas offered by the Con. Goldfields of South Africa, Ltd., for the best paper published hy that Institution during the previous year. The article was "Sampling and Dry Crusbing in Colorado."

THE following standing committees have heen selected hy the officers of the California Miners' Association: Executive Committee at Large—E. C. Voorheis, W. C. Ralston, T. L. Ford, C. H. Dunton, C. G. Yale, H. Z. Osborne and J. Bermingham, Jr. County Advisory Committee: Alameda—S. B. Christy of Berkeley, F. A. Leach of San Francisco; Amador—W. F. Detert of Jackson, J. B. Tregloan of Amador; Butte—A. Ekman of Oroville, W. P. Hammon of Oroville; Calaveras—A. I. McSorley of San Andreas, F. J. Solinsky of San Francisco; El Dorado—G. Clark of Placerville, A. B. Gould of Placerville; Fresno—A. R. Briggs of San Francisco, W. H. McKenzie of Fresno; Kern—J. Treadwell of Kern City, B. F. Brooks of San Francisco; Mariposa—C. C. Derby of Mount Bullion, A. H. Ward of San Francisco; Mono—R. T. Pierce of Lundy, R. H. Turner of Bodie; Nevada—F. Zeitler of Nevada City, W. F. Englebright of Nevada City; Placer—W. Nichols, Jr., of Dutch Flat, W. S. Graham of San Francisco; Plumas—G. Standart of Quincy, U. S. Webb of San Francisco; Sacramento—J. H. Batcher of San Francisco, A. C. Hinkson of Sacramento; Santa Clara—R. R. Bulmore of Los Gatos, T. Derby of New Almaden; San Francisco—L. Glass, G. H. Wallis; Shasta—F. Hurst of Redding, C. C. Bush of Redding; Sierra—F. R. Wehe of San Francisco, G. F. Taylor of Downieville; Southern California—T. B. Comstock of Los Angoles, J. B. Bushnell of Los Angeles; Tuolumne—F. Sutton of Sonora, W. H. McClintock of San Fraucisco; Yuba—W. B. Meek of Camptonville, F. R. Lord of Camptonville. Committee on Finance—A. Carrigan, J. O. Harrou, J. Sloss. Committee on Legislation—J. F. Davis, J. R. Tyrrell, W. C. Ralston, T. L. Ford, F. J. Solinsky, W. S. Keyes. Committee on Mineral Lands and Conservation of Water—E. C. Voorheis, M. de Vries, A. D. Foote, H. E. Picket, B. S. Rector. Committee on Department of Mines and Mining—W. C. Ralston, R. G. Lukens, T. L. Ford, C. H. Dunton. Committee on Dams—A. Caminetti, F. Searls, A. C. Hinkson, J. S. Mooser, W. B. Meek, A. B. Gould, A. I. McSorley.

Obituary.

A. DARLING, a pioneer miner of Bear Creek district, El Dorado county, Cal., died at Jacksonville, Tuolumne county,

D. GILMORE, 72 years of age. a pioneer miner of Montana, died of heart failure in his cahin in the mountains west of Helena on the 20th inst. Deceased discovered the Bald Butte mine.

D. J. DUNCAN, superintendent for the Hays M., M. & L. Co., at Camp Hays, in the Pineta mountains, Sonora, Mexico, died on the 14th inst. from pneumonia after a short illness.

F. A. SCHNEIDER, a pioneer mining and smelter operator of Mexico, died at El Paso, Texas, on the 2nd inst. of pneumonia. Deceased had been connected with smelting operations in Mexico for forty-one years.

C. H. BURCH, a pioneer miner of Oregon and California, died at Amity, Or., on the 9th inst. Deceased was born at Keytsville, Mo., July, 1828. Deceased went to Oregon in 1844. From 1878 to 1890 he was a member of the Oregon State Senate.

D. S. DANA of Salt Lake City, Utah, interested in Utah mines, died at Salt Lake City on the 18th inst., aged 78 years. In the '60s deceased was attorney of the Treasury Department at Washington, and later was a member of tho Supreme bench of Ohio.

A. J. HOLLAND, a pioneer miner of California and Nevada and formerly a resident of Mason Valley, Nev., died on the 6th inst. at the State Insane Asylum at Reno, where he had been confined for two years past. Deceased was 74 years of age and leaves a widow and a daughter.

P. J. DUCEY, a pioneer mining man of Cripple Creek district, Colo., died at Colorado Springs, Colo., on the 10th inst., of heart failure, aged 55 years. Deceased went to Colorado in 1868, was identified with the early mining history of that State and was one of the first prospectors to enter Cripple Creek. He is survived by six sons and daughters.

Cal., on December 31. Deceased was a native of Connecticut, aged 80 years. He was formerly owner of the Darling mine on Bear creek, which he sold to San Francisco men.

J. W. DRIPS, a pioneer miner of Colorado, died at Arvada last week. Deceased was born in Westmoreland county, Pa., March, 1833. In 1860 he went to Black Hawk, Gilpin county, Colo., and in 1863 removed to Clear Creek county, where he was treasurer of that county for eight years. In 1878 he returned to Gilpin and was engaged in mining. He was elected to the State Legislature in 1883. In Clear Creek county he was interested in mines near Empire and Georgetown, and in Gilpin county was locator of the Toronto silver mine. In later years he was a leaser of Cripple Creek mines. He leaves a widow and one son.

Commercial Paragraphs.

THE Brown Corliss Engine Co. of Corliss, Wis., is represented in St. Louis, Mo., by Edw. Field, 611 Commonwealth Trust Bldg.

THE Redfield Drill Co., Denver, Colo., reports shipping one of its hand power rock drills to W. L. Murphy, Kellar, Wash., and one to the Ajax M. Co., Burke, Idaho.

THE H. K. Porter Co. of Pittsburg, Pa., have a contract for four oil-burning locomotives for use on the National Tehauntepec Railway, which road S. Pearson & Co. of London, Eng., is building across Mexico.

THE C. O. Bartlett & Snow Co. of Cleveland, Ohio, have an order from the Dakota Pressed Brick Co., Deadwood, S. D., for one of their rotary dryers for drying fifty tons of sand a day, also conveying machinery.

GEO. CROCKER, president of the Zwoyer Fuel Co. of New York, has returned to San Francisco, Cal. The briquette machines made by the Zwoyer Fuel Co. are reported meeting with ready sale. J. Forbes Potter, 25 Broad Street, New York City, is treasurer and manager of the company.

FROM the W. S. Tyler Co., Cleveland, Ohio, comes a screen made from woven wire, subsequently rolled, and that works after the manner of slotted screens, with statement that the construction of the screen is such that it is easily cleaned, and that there is the minimum of tendency to blind or clog.

F. B. DUNCAN has been appointed manager of the Akron, Ohio, Electrical Manufacturing Co. About two years ago Mr. Duncan resigned the position of general superintendent, which he held for about five years, with the Northern Electrical Manufacturing Co., Madison, Wis., to accept a similar position in the Akron Co., and his recent promotion is evidence of the latter company's appreciation of his services.

THE Lunkenhoimor Co., Cincinnati, O., makers of superior brass and iron steam specialties, report that owing to the growing demand for their specialties they have again greatly increased their facilities, and are now in position to guarantee reasonably prompt shipments. They also report through their foreign branches an increasing export demand for their specialties and state that they will place some new specialties upon the market, which will be contained in a very complete catalogue to be issued in the course of a few months.

THE Henry W. Oliver Chemical and Metallurgical Library of Lafayette College, Easton, Pa., has received as a gift from a generous friend all the pamphlets, about 3000 in number, belonging to the library of the late Professor Johannes Wislicenus of the University of Leipsic. Professor Wislicenus was a famous chemist. He was a pioneer in the study of lactic acids and led in the work which gave to us our present knowledge of stereoisomerism. The library represents the collection of fifty years of great activity and will be a valuable addition to the Oliver library.

Trade Treatises.

"The American Crossley Gas Engine" is the subject of an unusually fine pamphlet, issued by the Power & Mining Machinery Co., 52-54 William Street, New York, N. Y.

The H. B. Sackett Screen & Chute Co., 4212-4230 State Street, Chicago, Ill., issue a 24-page compendium illustrative of their mine cars, revolving screens for quarrying and mine work, elevators, friction hoists, etc.

The 1904 Catalogue of the Knowles Steam Pump Works, 114-118 Liberty St., New York City, 150 pages, shows nearly half as many full-page illustrations of different types of direct-acting steam pumps, and will be supplied free upon request.

New Patents.

DEWEY, STRONG & CO.'S SCIENTIFIC PRESS PATENT AGENCY, 330 Market St., S. F., has official reports of the following U. S. patents issued to Pacific Coast inventors:

FOR WEEK ENDING JANUARY 12, 1904.

749,167.—WRENCH—W. E. Carter, Baker City, Or.
749,422.—CLOSURE—E. E. Chapman, Los Angeles, Cal.
749,423.—CLOSURE—E. E. Chapman, Los Angeles, Cal.
749,475.—DECORTICATING MACHINE—R. A. Clifford, S. F.
749,426.—GATE—O. L. Compton, Union, Or.
749,085.—VAPOR BURNER—Crane & Restine, San Diego, Cal.
749,172.—SNOW PLOW—O. Cutting, Seattle, Wash.
749,128.—MAIL BOX—Dusenbury & Kelly, S. F.
749,282.—RESERVOIR—P. Englund, Chico, Cal.
749,288.—BOTTLE—H. Hahn, S. F.
749,188.—WINDLASS—J. Hansen, North Cove, Wash.
749,191.—WEIGHING APPARATUS—G. Hoepner, S. F.
749,073.—COUCH—J. Hoey, S. F.
749,140.—FLOORS, SIDEWALKS, ETC.—P. H. Jackson, S. F.
749,299.—HORSESHOE—A. W. Jones, Pacific Grove, Cal.
749,491.—WATER MOTOR—J. D. Lee, Salem, Or.
749,390.—MEASURING APPARATUS—L. P. Lowe, S. F.
749,216.—TRANSPORTING APPARATUS—G. W. McNear, Jr., Oakland, Cal.
749,697.—FRUIT PITTER—Middlekauff & Schirm, Los Angeles, Cal.
749,573.—LEMON SQUEEZER—D. H. Mosteller, S. F.
749,447.—DRAFT CONNECTION—C. S. Payne, S. F.
749,630.—ORE GRINDER—W. G. Phipps, Stockton, Cal.
749,451.—STEAM GENERATOR—F. Saffell, Fresno, Cal.
749,327.—DUST GUARD—Sager & Dow, Seattle, Wash.
749,454.—BOLT HOLDER—J. S. Scott, San Jose, Cal.
749,159.—WAD SORTER—B. W. Stevens, Pinole, Cal.
749,646.—WOOD HOLDER—J. E. Wallin, Tacoma, Wash.
749,509.—TROLLEY—W. D. Williams, Kirkland, Ariz.
749,417.—HYDRAULIC NOZZLE—J. A. Yeatman, S. F.
749,652.—WHEEL HUB—Youmans & Rand, Vancouver, Wash.

Notices of Recent Patents.

Among the patents recently obtained through Dewey, Strong & Co.'s SCIENTIFIC PRESS U. S. and Foreign Patent Agency, the following are worthy of special mention:

WAD SORTER AND ASSEMBLER.—No. 749,159. Jan. 12, 1904. B. W. Stevens, Pinole, Cal. Assigned to California Powder Works of Hercules, Cal., a corporation. This invention relates to an apparatus the purpose of which is to separate mixed gun wads or disks of equal diameter, but of unequal thicknesses, and then to set up and assemble the wads in groups or tubes, with their flat sides remaining parallel and contiguous. It consists of one or more hoppers into which the wads are first placed, means for conveying the wads from the hoppers upon an endless traveling belt, means for assorting the thicker from the thinner wads, means for assembling the wads in tubes from which they may be used in the cartridge loading machines.

STEAM GENERATOR.—No. 749,451. Jan. 12, 1904. F. Saffell, Fresno, Cal. One-half assigned to R. J. Powers, of San Leandro, Cal. This invention relates to an apparatus for generating steam and it is especially designed to be used in conjuction with oil burning devices and to supply the steam necessary or desirable to be used in conjunction with such oil burners. It consists of a chamber adapted to lie horizontally within the furnace or fireplace, so as to be subjected to the desired heat, means for supplying water and delivering it at the distant end of the generator, overflow riffles disposed upon the bottom between said end of the chamber and the receiving end, and a dome or elevation from which the steam is delivered. There is also a means for protecting the generator from too intense heat of the fire.

DRAFT CONNECTIONS FOR RAILWAY CARS.—No. 749,447. Jan. 12, 1904. C. S. Payne, San Francisco, Cal. One-quarter assigned to Louise U. Larue of San Francisco, Cal., and E. R. Rice of Sausalito, Cal. This invention relates to a draft connection for railway and like carriages which are made up into long trains. It consists in connections between the couplers of the train with intermediate yielding or compressible springs, whereby the connecting rods are taken up when the train is checked or slows down, and which springs allow the power to be applied gradually without danger of breaking the rods or connections.

HYDRAULIC NOZZLE AND JOINT.—No. 749,417. Jan. 12, 1904. J. A. Yeatman, San Francisco, Cal. This invention relates to a hydraulic nozzle and anti-frictional joint for the conducting pipes thereof, which pipes are turnable in order to change the direction of water flowing through them; and it is especially applicable to that class of joints which are used in conjunction with pipes and nozzles conveying water to be used for washing down banks of earth as in placer mining. By this construction a water-tight joint is insured, and the guided and separated rollers relieve the joint of excessive friction under high pressure.

COUCH.—No. 749,643. Jan. 12, 1904. John Hoey, San Francisco, Cal. This invention consists in a novel construction of woven wire in connection with elastic cables stretched to form a seat portion of the couch and its disposition in conjunction with the raised and curved head of the couch in such a manner that the edge of the fabric can be brought out flush with the side rails of the couch. It also consists in the formation of the head in such a manner that the woven-seat fabric is carried beneath the head portion, and the latter may also be formed of woven wire fabric having a tension cable or wire edge at its junction with the seat portion of the fabric, so as to form a continuous elastic connection at this junction.

Latest Market Reports.

SAN FRANCISCO, January 22, 1904.

METALS.

SILVER.—Per oz., Troy: London, 26½d (standard ounce, 925 fine); New York, bar silver, 56¾c, refined (1000 fine); San Francisco, 56¾c; Mexican dollars, 43@44c San Francisco, 44c New York.

COPPER.—New York: Standard, $12.75; Lake, 1 to 3 casks, $13.00; Electrolytic, 1 to 3 casks, $12.87½; Casting, 1 to 3 casks, $12.75; San Francisco: $15.00. Mill copper plates, $17.00; bars, 18@24c. London: £57 15s spot per ton.

Copper remains unchanged from last week's quotations, except in London, where the price has fallen nearly $10 per ton. Following are the figures of German consumption of foreign copper for the months January-November, 1903, compared with same period of 1902-1901:

	1903. Tons.	1902. Tons.	1901. Tons.
Imports	80,093	74,183	58,965
Exports	9,328	8,188	9,198
Consumption	70,765	65,995	49,767

LEAD.—New York, $4.65; Salt Lake City, $3.50; St. Louis, $4.25 San Francisco, $4.50, carload lots; 4¾c 1000 to 4000 lbs.; pipe 6½, sheet 7, bar 5¾c; pig, $4.75. London: £11 16s 3d ₱ long ton.

SPELTER.—New York, $5.05; St. Louis, $5.00; London, £21 10s ₱ ton; San Francisco, ton lots, 6¾c; 100-lb. lots, 7c.

TIN.—Now York, pig, $28.60 @ 28.90; San Francisco, ton lots, 31c; 500 lbs., 31½c; 200 lbs., 32c; less, 32½c; bar tin, ₱ lb., 35@37½c. London, £130 5s.

PLATINUM.—San Francisco, crude, $18.00 ₱ oz.; New York, iugot, $19.00 ₱ Troy oz. Platinum ware, 75 @ 82c ₱ gram.

QUICKSILVER.—New York, $46.50@47.00, large lots; London, £8 7s 6d; San Francisco, local, $44@44.50 ₱ flask of 76½ lbs.; Denver, $48.00. Export, $42.00@42.50.

BABBITT METAL.—San Francisco, No. 1, 10c; No. 2, 7c; No. 3, 6½c; extra, 17½c; genuine, 31½c; Eclipse, 35c.

SOLDER.—Half-and-half, 100-lb. lots, 20.00c; San Francisco, Plumbors', 100-lb. lots, 16.80c.

ZINC.—Metallic, chemically pure, ₱ lb., 50c; dust, ₱ lb., 10c; sulphate, ₱ lb., .04c.

NICKEL.—New York, 50@60c ₱ lb.: ton lots, 40@47c.

ALUMINUM.—New York, No. 1, 99% pure ingots, 35c; No. 2, 90%, 30@34c.

LUMBER.—(Retail): Pine, ordinary sizes, $24.00@25.00; extra sizes higher; redwood, $28.00@30.00; lath, 4 feet, $4.50 @5.00; pickets, $21.00; shingles, $2.50 for No. 1 and $2.25 for No. 2; shakes, $13.50 for split and $15.00 for sawed: rustic, $28.00 @35.00.

NAILS.—Per keg (list prices): No. 20d to 60d, Wire, $3.35; Cut, $3.55; 10d to 16d, Wire, $3.45; Cut, $3.35; 8d Wire, $3.50; Cut, $3.50; 6d and 7d, Wire, $3.60; Cut, $3.60; 4 and 5d, Wire, $3.70; Cut, $3.70; 3d, Wire, $3.85; Cut, $3.85; 2d, Wire, $4.10; Cut, $4.10. Special rates for carload lots.

LIME.—Santa Cruz, $1.25 country, $1.25 city ₱ bbl.

CEMENT.—Imported, $2.25@2.50 ₱ bbl.; California carload lots, $2.00 f. o. b. at works; small lots, $2.25 ₱ bbl. in sacks, 4 sacks to bbl.

STRUCTURAL MATERIALS.

IRON.—Pittsburg, Bessemer pig, $13.85 @14.10; gray forge, $12.85; San Francisco, bar, 3c ₱ lb., 3½c in small quantities.

STEEL.—Bessemer billets, Pittsburg,

WELL PLEASED is the verdict of every user of The Burt Exhaust Head.

CAPS.—3x, $5.50 per 1000; 4x, $6.50; 5x, $8; Lion, $9, in lots not less than 1000.

FUSE. –Triple tape, $3.60 per 1000 feet; double tape, $3.00; single tape, $2.65; Hemp, $2.10; Cement No. 2, $3.00; Cement No. 1, $2.65, in lots of 3000 feet and up.

CANDLES.—Granite 6s, 16 oz., 40s., 11½c ℔ set; 14 oz., 40s., 10c.

CHEMICALS. — Cyanide of potassium, 98%–99%, jobbing, 23@24c ℔ lb.; carloads, 23@23½c; in tins, 30c; soda ash, $2.00 ℔ 100 lbs.; hyposulphite of soda, 3@3½c per lb.; caustic soda, in drums, 3@3½c ℔ lb.; Cal. s. soda, bbls., $1.20@1.40 ℔ 100 lbs.; sks., $1.05; chlorate of potash, 12@13c; nitrate of potash, bbls., 10c; caustic potash, 10c in 40-lb. tins; roll sulphur, 2½@2¾c; powdered sulphur, 2@3c; flour sulphur, French, 3½@3¾c; alum, $2.00@2.25; California refined, 1¾@2c; sulphide of iron, 8c ℔ lb.; copper sulphate, 5¼@5¾c; chloride of lime, spot, $2.50@2.75; sulphuric acid, in carboys, 66° B, 1¾@2c ℔ lb.; nitric acid, carboys, 8c ℔ lb.

BONE ASH.—Extra No. 1, 5@6c ℔ lb. No. 1, 4@5c.

OILS.—Linseed, boiled, bbl., 49c; cs., 54c; raw, bbl., 43c; cs., 48c; Lucol oil boiled, bbl., 44c; cs., 49c; raw, bbl., 42c; cs., 47c. Kerosene—Pearl, per gal., 21½c; Astral, 21½c; Star, 21½c; Extra Star, 25½c; Eocene, 24½c; Elaine, 27½c; Water White, in bulk, 15c; Mineral Seal, iron bbls., 19c; wooden bbls., 21½c; cs., 25c; Mineral Sperm, cs., 26½c.; Deodorized Stove Gasoline, bulk, 17c; do., cs., 23½c; 86° Gasoline, bulk, 25c; do., cs., 31c; 83° Naphtha or Benzine, deodorized, in bulk, per gal., 13c; do., in cs., 19½c; Lard Oil, E W. S., bbl., 85c; cs., 90c; Neats-foot Oil, pure, bbl., 75c; cs., 80c; Sperm, crude, 50@55c; Natural White, 70c; Bleached, do., 75c; Whale Oil, cs., 50@55c.

WHITE LEAD.—Per lb., in kegs: 500 lbs. and over at one purchase, per lb., 6½c; less than 500 lbs., per lb., 7c; in 25-lb. tin pails, ½c ℔ lb. above keg price; in 1 and 5-lb tin cans, 100 lbs. per case, ½c. per lb. above keg price. Dry Lead—In bbls., 1 ton and over, 6½c; do. in kegs, 7c.

RED LEAD.—500 lbs. and over at one purchase, ℔ lb., 6½c; less than 500 lbs., 7c.

LITHARGE.—Pure, in 25-lb. bags, 8@9c ℔ lb.

BORAX.—Concentrated, 6@7c ℔ lb; powdered, 8@10c; fused, 20@25c; crystal, 7c; calcined, 25c.

MANGANESE.—Pure, ℔ lb., 60c.

SODIUM.—Metal, ℔ lb., $1.00.

BISMUTH.—Subnitrate, ℔ lb., $1.75.

MERCURY.—Bichloride, ℔ lb., 90c.

MOLYBDENUM.—$2.00 ℔ lb.

CHROMIUM.—90% and over, ℔ lb., $1.00.

PHOSPHORUS.—American, ℔ lb., 75c.

SILVER.—Chloride, ℔ oz., 90c@$1.00; nitrate, 55c.

ALUMINUM.—No. 1., 99%, small lots, 37c ℔ lb.; 100 lbs., 35c; 1000 lbs, 34c; ton lots and over, 33c, Pittsburg. No. 2, 90%, small lots, 34c; ton lots and over, 31c, Pittsburg.

URANIUM.—Oxide, ℔ lb., $3.50.

(These prices are wholesale, f. o. b. San Francisco, unless otherwise noted.)

SITUATIONS WANTED.

A SOBER, INDUSTRIOUS YOUNG MAN DESIRES a situation as Surveyor, Assayer, Draughtsman and Bookkeeper. Has had three years' technical training and four years' practical experience in gold and quicksilver. Am conversant with the estimation of ore and the preparation of maps and reports. Best of references as to ability and character. Address "M.," care of this office.

A YOUNG MINING ENGINEER DESIRES position as assistant; assayer and good draughtsman; State licensed surveyor for California. Address C. R., care Min. and Scientific Press.

ASSAYER AND CHEMIST DESIRES POSITION in mine or laboratory. Address V. H., this office.

COMPETENT AND RELIABLE MAN DESIRES position as manager, assayer or chemist with mining company in this or foreign country. Address "Stanton," 736-14th St., San Francisco.

EXPERIENCED SUPERINTENDENT, ENGINeer, Metallurgist; technically and liberally educated; 15 years handling men and machinery of smelters, mills and mines. See testimonials. Address Prof. Stickney, Mountain View, Cal.

EXPERIENCED MILLMAN WISHES POSItion. Address Box 202, Enterprise, Cal.

HIGH-GRADE MAN WILL ACCEPT MODERate salary. **PRACTICAL MINE FOREMAN and All Round SUPERINTENDENT.** Inquiries cheerfully answered. Address "Wire Cable," Sonora, California.

MANAGER LARGE GOLD MINING AND milling company in Arizona desires to change his location and obtain similar position with desirable company elsewhere. Best of references from present employers. Address I. C., this office.

MILL AND SMELTER SUPERINTENDENT, at present disengaged, wishes similar position with responsible company; college graduate with varied experience. Best of credentials furnished and required. Address "Gluckauf," care this office

MILL FOREMAN WANTS POSITION; 20 years' experience; good references; correspondence solicited. Address Mill Foreman, 1056 South Gaylord St., Denver, Colo.

MINING ENGINEER AND METALLURGIST, technical graduate, with large experience as superintendent, manager and consulting engineer of mines and mills, desires a position. Best references. Speaks Spanish fluently. Address "Ingeniero," care of Mining and Scientific Press.

POSITION WANTED BY NEW YORK ELECtrical engineer with Pacific Coast company. Experienced in construction work and selling. A position where he can work into the selling end preferred. References from company with which he is now connected. Address G. P., this office.

SUPERINTENDENT IS OPEN FOR POSITION to develop gold or copper properties; experienced miner; can make underground maps and models, also do the assaying; speaks Spanish; good references from past companies. Address "Develop," care this office.

WANTED, POSITION AS SUPERINTENDENT or Manager of "Gold Mining Property;" 12 years' experience in practical mining, also assayer, mine surveying and drafting. Will furnish surveying and drafting instruments, and will accept 50% of salary in stock in a "Good Mining Co." O. F. Matkin, care of Concentrator, C. C. C. Co., Cananea, Sonora, Mexico.

WANTED—POSITION WITH MINING COmpany as manager or assistant. Examinations, surveying, assaying; also familiar with drift and hydraulic mining. Best of references. Address W. H. J., this office.

WANTED, POSITION BY MACHINIST AND Engineer; efficient in steam, electricity and compressed air; seven years' experience at mines; good references. Address Box 54, care of Mining and Scientific Press.

WANTED—POSITION AS SUPERINTENDENT or assistant of copper mines and smelters; competent all round man, good assayer, analyst and draughtsman; can handle labor; speaks Spanish. Address "Smelter," care this office.

YOUNG MAN GRADUATED AS CHEMICAL Engineer and Ph.D. at leading polytechnic school and university of Europe, having made special studies in electro-chemistry, wants position as chemist with mining or metallurgical company. Address B-36, care of Lord & Thomas, Chicago.

YOUNG MAN WITH SOME EXPERIENCE and training in chemistry, metallurgy and general engineering, wants work at mine or any place where he can get additional experience and training. Address "Espanol," care of this office.

HELP WANTED.

WANTED—MINE SUPERINTENDENT OF EXperience, who thoroughly understands handling of gold-bearing ores and management of mine and men. Must be willing to take part of salary in stock of company until mine is on paying basis. Mine is in California. Only thoroughly competent men need apply. References required and given. Address G. Mines, care of Mining and Scientific Press, San Francisco, Cal.

WANTED.

WANTED, BY WORKING CYANIDER, Quantity low grade gold ore, sand, or slimes, who wishes to work same on royalty or will put working plant on same for interest in property. Send description to Frank G. Cline, Gold Hill, New Mex.

ASSESSMENT NOTICES.

EUREKA CONSOLIDATED DRIFT MINING Company.—Location of principal place of business, San Francisco, California; location of works, Placer County, California.

Notice is hereby given, that at a meeting of the Board of Directors, held on Tuesday, the 12th day of January, 1904, an assessment (No. 39) of one-half (½) cent per share was levied upon the capital stock of the corporation, payable immediately in United States gold coin, to the secretary, at the office of the company, Room 3, No. 214 Pine street, San Francisco, California.

Any stock upon which this assessment shall remain unpaid on the 13th day of February, 1904, will be delinquent, and advertised for sale at public auction; and, unless payment is made before, will be sold on MONDAY, the 7th day of March, 1904, to pay the delinquent assessment, together with the costs of advertising and expenses of sale.

By order of the Board of Directors.

CHAS. W. DIXON, Secretary pro tem.

Office—Room 3, No. 214 Pine street, San Francisco, California.

MARINA MARSICANO GOLD MINING COmpany.—Location of principal place of business, San Francisco, California; location of works, Sunny Hill, Sbasta County, California.

Notice is hereby given, that at a meeting of the Board of Directors, held on the 18th day of January, 1904, an assessment (No. 37) of five (5) cents per share was levied upon the capital stock of the corporation, payable immediately in United States gold coin, to the secretary, at the office of the company, 415 Front street, San Francisco, California.

Any stock upon which this assessment shall remain unpaid on the 29th day of February, 1904, will be delinquent, and advertised for sale at public auction; and, unless payment is made before, will be sold on MONDAY, the 21st day of March, 1904, to pay the delinquent assessment, together with the costs of advertising and expenses of sale.

By order of the Board of Directors.

CHAS. BOVONE, Secretary.

Office—415 Front street, San Francisco, California.

The Height of Excellence

Manufacturers cannot make a better roofing than P. & B. Ready Roofing, for it is the result of skill, experience and the best materials produced. For 17 years this roofing has given thorough satisfaction in every part of the globe, until now builders look to it as the only ready roofing that can be absolutely depended upon.

P. & B. Ready Roofing can be shipped at a very low freight rate—comes in rolls; can be quickly and easily laid; anyone can do it.

The Value of a Prospect.

There is usually less difficulty in placing a valne on a developed mine than on a good prospect. In the one case there is a tangible proposition—a developed mine. The shafts and levels, or tunnels, with numerous connecting raises or winzes block out the ore into sections of greater or less size, which may be inspected on three or four sides. The variable widths of vein may be observed and the average computed with approximate accuracy. This together with the assay value of the vein at stated distances throughout the mine cuttings furnishes a basis for estimating. Ore actually in sight, probable ore and possible ore, and the valne of the mine present and prospective are thus arrived at. The securing of detailed information of this sort is a more or less lengthy process, requiring good judgment, skill aud honesty, and if any considerable amonnt of money is at stake, various precautionary measures must be taken to insure that the samples remain intact aud that no opportunity is presented for salting them by any person who might be disposed to do so.

With the prospect it is different. The development and ore exposures are limited and there is little upon which to estimate the value of the property. The vein may present a good appearauce and conform to the usual conception of the geological requiremeuts of a vein which has elsewhere been developed into a profitable mine. The values may be present in sufficiently attractive amount, and still no more than a prospective valne can be placed on such property. The owner usually places his estimate higher than any other person would, and an experienced mining engineer, while admitting its great possibilities, would probably place a lower prospective valuation on it than the owner, even if he were employed by the latter to examine and pass judgment on the mine, its requirements and future possible value. It is an easy matter to condemn a prospect, disregarding what may be evident, and allowing nothing beyond what can actually be seeu. The miniug engineer, to preserve his reputation, must of necessity be cautious, but he need not be pessimistic, for his ultra-conservatism may later work to his disadvantage. The man of experience realizes that mines are made, and their making is ofteu a slow and expensive process. Some of the most noted mines of the present day have within their history beeu on the verge of closing down permauently, but by persevering aud introducing methods which would reduce expenses, the properties have been pulled through a period of depressiou, and are to-day largely profitable. In these instauces an engineer, overcautious or fearful of making a mistake, would have closed the properties and it would have beeu many years before they would have been reopeued. The prospect, if it be a good one, always has a speculative valne, and this value is an unknowu quantity. In view of this fact a stated value is fixed upon it and the mine must then work out its owu salvatiou on the progressive plan. It is not evident that it is a greater crime to overvalue a good prospect than it is to overcapitalize au industrial stock in some other line of business.

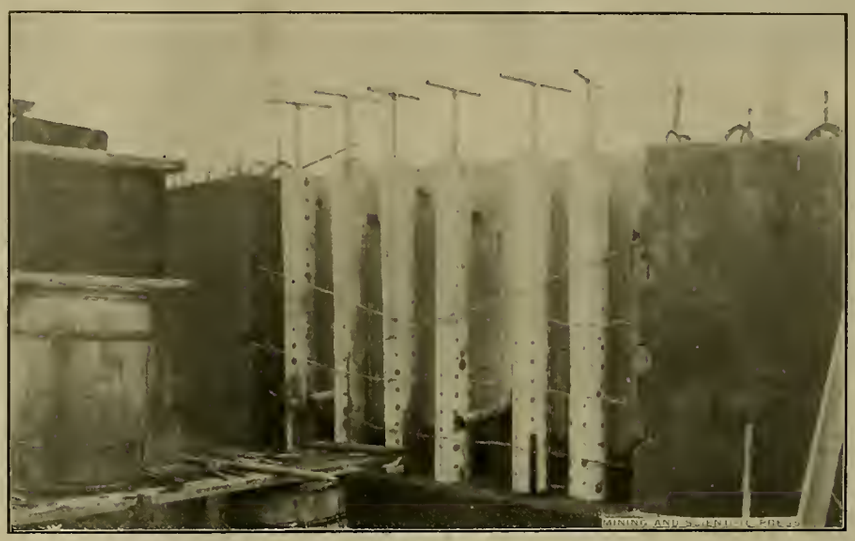

Fig. 1.—Hollow Walls; Forms in Place. (See Page 76.)

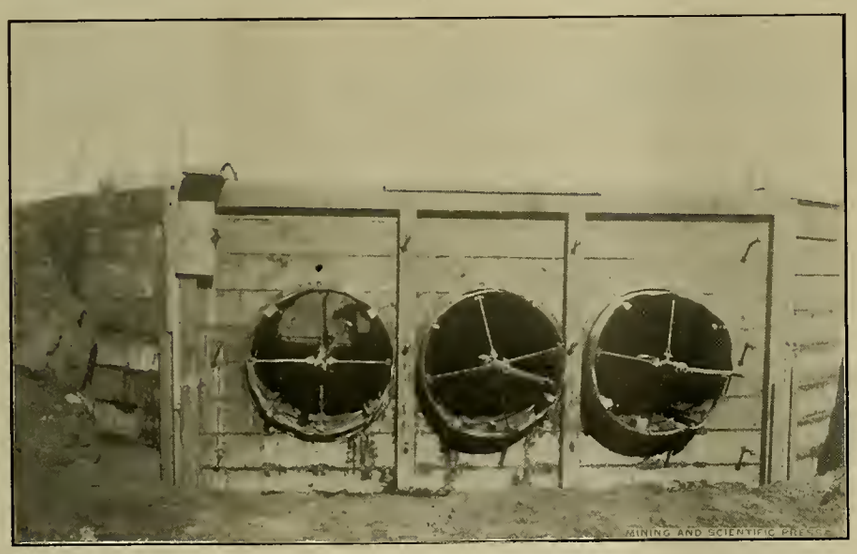

Fig. 4.—Forms in Place. (See Page 76.)

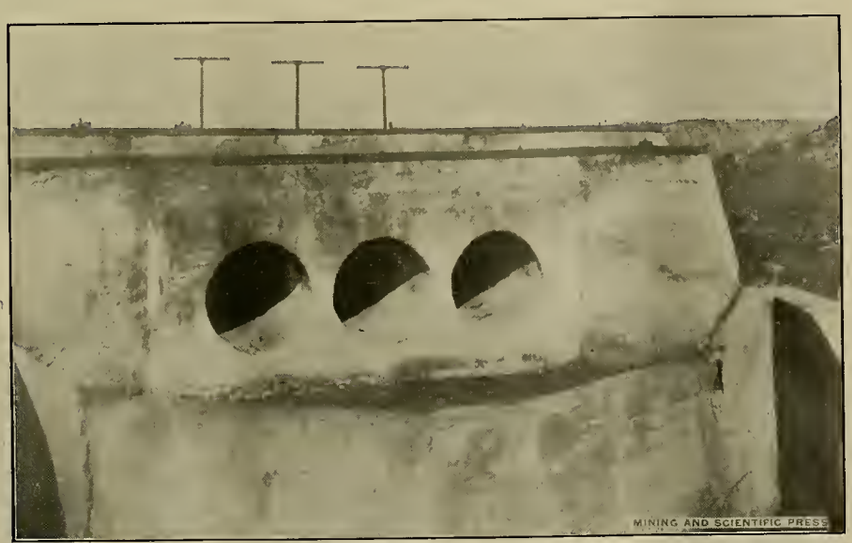

Fig. 6.—Combined Gate and Drop. (See Page 76.)

IN mining aud metallurgy the practical and the scientific branch sometimes apparently clash, but without doubt the two are inter-dependent. The purely scientific student deprecates methods and practice which he does uot fully understand and appreciate, while the practical man without scientific attainment feels confident that he is right because he is successful, but it is being daily demonstrated that it requires both science and practical knowledge to accomplish the best results. The practical miner was surprised, if not disgusted, with the noted engineer aud geologist who only gave a passing glauce at a large and payable ore body, aud spent an hour in a careful examination of some minor occurrences of ore in the walls. To the geologist the extent and possible value of the large ore body were at once apparent, but iu a study of the lesser phenomena of the mine he hoped to be led to some valuable conclusion as to the genesis of the ore deposits of the mine as a whole. Each understood his business, but uuderestimated the importance of the other's knowledge.

Mineral in Railroad Grants.

A controversy has arisen in southern Wyoming between the Union Pacific Railroad Co. and prospectors who are searching on the odd uumbered sections claimed by the railroad company under the grant from the Government. The grant in question excepts mineral lands, bnt does not include those containing coal or iron. Bnt when land is referred to as "mineral" it must have been known as mineral prior to the time when the grant attached, and the discovery of a gold, copper or other metal mine after the title has passed to the railroad, is not inclnded in the land excepted from the grant. The Wyoming prospectors are searching for both coal and petroleum, but as coal lands are distinctly excepted from the operation of the statute which reserves the mineral lands, the prospectors have little to hope for in that direction. Petrolenm lands, however, are recognized as mineral and are subject to location on the public domain and lands within the railroad grants which are discovered to be oil bearing before the railroad company has acqnired title to them, are subject to location as mineral lands. It is reported that the Union Pacific Co. has posted notices warning prospectors that they must confine their explorations to the lands of the public domain. Prospectors, before searching for mineral on these lands, would do well to ascertain the state of the title to any particular section of land, for where the railroad company has perfected its title the case of the prospector is hopeless.

No Claims in Irrigation Reserves.

It has been decided by the Secretary of the Interior that mining claims cannot be entered in lands withdrawn for reservoir sites, or for permanent works uuder the irrigation law. The secretary holds that the withdrawals of these lands under the authority of the reclamation of arid lands act of June 17, 1902, of lands deemed by the department necessary for any irrigation work, have the force of legislative withdrawals, and consequently are effective in withdrawing all of these lands from any other disposition, and in his opinion no right is vested in the locator of a mineral claim until final proof has been snbmitted and the purchase money paid. This latter presumably refers to mineral locations made within the irrigation lands withdrawu from entry, and upon which patents have not been secnred. Thus far abont 30,000,000 acres have been reserved for reservoir sites or for the construction of permanent irrigation works, and in order not to defeat the purpose of the Government, and to foil any attempt to locate aud hold mining or timber claims within these reservations, at exorbitant prices, the Department of the Interior has made the ruling above referred to.

Selection of Metallurgical Method.

The concentration of ores cousists in separating a heavy, and usnally a more valuable, portion from a lighter and less valnable portiou. This is accomplished by various methods. Among these the most rnde and least complete is sorting nnderground in the mine. A second stage toward improvement is hand sorting after coarse crushing on the surface, the various ores being picked ont by hand from a revolving table or from a moving belt conveyor. A further and closer concentration may be made by means of the varions mechanical concentrating devices. These include jigs, belt-vanning machines, shaking tables, circular tables and buddles, and the dry concentrating machines depending for success in operating on an intermittent blast of air. Each of these various machines, togcther with the canvas tables and hydranlic sizers, in which latter class belong the spitzkasten, etc., have a field of nsefulness, though often they are not properly applied when they may do the best work. Excepting the dry concentrators above mentioned, all of these devices depend to a large extent upon the sorting power of water, aud the snccess is generally proportional to the adaptability of the machine to the ore. A coarse first-prodnct jig would be useless in the treatment of slimes, aud the canvas table would accomplish no valuable result on coarse ore.

Smelting is as much a process of concentration as any of the operations carried ou by means of vanners, jigs, or other mechanical apparatus, and not infreqnently the same ore may be succcssfully treated by either process. By successfully is meant success in a practical or mechanical way, but the economic resnlt may be a loss in one case and profit in the other. A mine situated at a distance from a railroad in a semi-arid region was operated for several months successfully—in a mechanical way—by smelting. The ore was a typical smelting mixture and the matte made ran high and contained a high percentage of the precions metals, but the enterprise was eventnally abandoned, for the reason that costs were so high as to absorb all that should have been profit. The property was closed down, and after a time a lease was given a number of men who overhauled an old mill and prepared to concentrate the ore. This was done at comparatively nominal expense, and success, both mechanical and financial, was the result. The smelter had made a 40% matte at a heavy cost, while the concentrating mill turned ont a 40% copper coucentrate, which also contained the precious metal values as well, at a cost of $3 per ton. This illustrates the need for careful consideration of the installation of a process or of any expensive machinery, for without due consideration haviug first been given such a matter a failure may resnlt where success is possible. There are situations where the difference of cost between smelting and milling complex ores may not be far apart, or may in some cases even be in favor of the smelter. Mistakes of the sort above mentioned are not of infrequent occurrence. It is not only necessary to know that the ore of a certain mine contains a given percentage of copper, or a stated amount of gold or silver. It must be known what process is best adapted to the reduction of this ore at the lowest cost. Amalgamation and chlorination or cyanidation may do it, bnt better economic results may be obtained by concentration and shipment.

There are many men who are first-class miners, who know every detail of mining from the breaking of the groud in a prospect pit to a developed property several thousand feet deep, and yet some of these men have a limited knowledge of metallurgy. The more cautions of these do not hesitate to employ men of experience to determine what is the best treatment for ores with which they are not wholly familiar themselves, and this frequently insures success.

Mine Accidents.

Two distressing mine accidents are chronicled in the daily press the past week—one at the Harwick coal mine in western Pennsylvania, where nearly 200 men lost their lives as the result of the explosion of fire damp—the other was the hoisting of a cage containing sixteen miners into the sheave wheel at the Independence mine at Victor, Colo., by reason of which fifteen were killed and one seriously injured. The cause of this accident has not yet been learned. Each of these disasters teach a lesson which it seems only such unfortunate and distressing occnrrences can emphasize; first the absolute necessity of the most perfect veutilation possible iu coal mines generating large amounts of fire damp, and second, the use of rigidly tested machinery at the mouth of mine shafts and the employment of only those men who are suited to the trying situation of hoisting engineer. There is an iunumerable number of men who understand the operation of hoisting engines and rnu them satisfactorily, when rock or materials only are to be handled, and many of them may also safely be trusted to handle skips and cages carrying men, bnt there are many who lose their confidence when men are on the cage. At the slightest irregularity in operatiou of the engine, or the appearance of an nnexpected sign their self-possession flees and they are as likely to tnrn on a full head of steam as to cut it off and apply the brakes at an uexpected signal. The hoisting engineer occupies a position of grave responsibility. A man who is pre-occupied, thoughtless, or a dreamer, has uo business at a hoist. Such a man might safely have charge of an engine running a mill or some other machinery where the engine continues to run steadily hour after hour, but the hoisting engineer must have nerve, self-control and presence of mind uuder all conditions. The best man at the hoist is an engineer who is also a miner, and who has had abundant practical experience underground. He should also be familiar with every foot of the shaft. He then can intelligibly interpret every signal. He knows every crook and turn in the shaft, shonld there be such, and runs accordingly. At some mines an electric or other bell is provided which rings upou the approach of the skip to within 50 or 100 feet of the collar of the shaft. This contrivance is highly recommended by many, but it is a dangerous device, for in the event of failnre to ring the skip may approach the collar of the shaft under full speed and then overwiuding is almost inevitable. The skip dashes agaiust the sheave timbers, the cable parts and the usnal resnlt follows. Nearly all cages are provided with safety clntches, bnt too often these fail to work properly. The iustance at the Independence mine was no exception, for the cage fell 1500 feet into the sump. Skips are occasionally provided with safety clutches, but more frequently they are not. A law should make such provision compulsory, even in incline shafts, and they should be tested daily to know that they are in perfect working order.

The disaster in Pennsylvania produced the usual uumber of heroes who unhesitatingly ventured into the wrecked mine in the face of almost certain death with the hope of rescuing some who might still be alive, and a number of these brave men sacrificed their lives as a result.

It appearing from a carefnl estimate of the cost of a snitable bnilding to accommodate the several engineering societies in New York City would exceed the $1,000,000 offered by Andrew Carnegie for this purpose, Mr. Carnegie has increased his offer to $1,500,000, provided the Society of Civil Engineers would join with the other societies. These include the American Institute of Mining Engineers, the American Institute of Electrical Engineers, the American Society of Mechanical Engineers and the Engineers' Club.

CONCENTRATES.

THE coefficient of linear expansion of concrete is 0.0000029 per 1 C.

✣✣✣✣

THE unit for measuring electre motive force is the "volt," named from Volta, who suggested it. It measures the intensity of the electric current.

✣✣✣✣

THE rock specimon from Fresno, Cal., is a silicified rock evidently intrusive (dike) containing hard hematite in a small vein through tbe center of the piece. Quartz is also prosent in veinlets.

✣✣✣✣

THE Federal mining laws apply in the Territories and in Alaska the same as in the States, the only difference in either States or Territories being where there are State or local laws, and these cannot conflict with those of the United States.

✣✣✣✣

THE various kinds of fabric used in sluices for catching fine gold are cocoa matting, usually made for the purpose, and resembling that used on floors, though somewhat more coarse, and gunnysacking of varying texture, the kind boing determined by experiment.

✣✣✣✣

THE arrastra is a cheap, convenient and easily constructed gold mill, and does excellent work as an amalgamator, but in these days of good and inexpensive quartz mills of many types the arrastra is becoming yearly more of a curiosity, and a few years later will be seen no more in America.

✣✣✣✣

THERE are numerous occurrences of chromo iron in California, but few of these are producing, tho most easily workable deposits, as far as known, having been worked out. Tbe present price of the ore renders the exploitation of more remote or less favorably situated deposits unprofitable.

✣✣✣✣

HOLES can be put down to a depth of 18 to 20 feet hy the men by means of a churn drill. A good drill for this purpose may be made of a piece of pipe at each end of which is welded a piece of drill steel. The hit at one end should be broader than at the other. This will be found of assistance in reaching a greater depth.

✣✣✣✣

ACETIC ACID will dissolve lead oxide or carbonate, wulfenite, (molyhdate of lead) and some other lead ores. When in solution tbe presence of lead may bo detected by adding a solution of potassium iodide which precipitates a yellow cloud of iodide of lead. This is said to be a good test for the presenco of lead in ore in small amount.

✣✣✣✣

THE exhaust of a steam engino may be employed in a variety of useful ways. One of the most practical and economical uses is to heat the feed water of the hoiler, this being accomplished in a variety of ways. It will reduco the fuel hill from one-third to one-half. It may also he used to heat the chango room of a mine, tho hot water being employed for this purpose.

✣✣✣✣

THE standard of measurement of the volume or quantity of an electric current is the quantity of gas evolved in the decomposition of water hy the current. That amount of current will liberate 10.4 cubic centimeters of mixed gas from water per minute. This unit of measurement has heen called after the name of an eminent French scientist—Ampore; abbreviated amp.

✣✣✣✣

CADMIUM is tin white in color, is malleable, ductile and when fresh has a brilliant silvery luster, but this soon disappears on exposure. It is found associated with zinc ores, and closely resemhles that metal. It can be beaten into a thin foil or drawn into fine wire, hut when heated to ahout 80° C. it becomes very brittle and is easily powdered, in which property it resemhles zinc.

✣✣✣✣

WHEN a pit in a placer mine hecomes so deep that men helow cannot shovel into the sluice hox, a platform may he arranged midway hetween the hedrock and the sluice box, when one man on the platform can usually shovel in as much as two men bolow will throw up to him, as shoveling is easier on a platform than on bedrock, and he is not obliged to lose time in picking up the gravol.

✣✣✣✣

A STANDARD 30-MESH WIRE SCREEN is made of No. 28 wire, having a diameter of 0.0162 inch. The diameter of the moshes is 0.0171 inch, equivalent to 0.43 millimeter. A 40-mesh screen is made of No. 31 wire, the wires having a diameter of 0.0132 inch. The width of aperture is 0.0118, equivalent to 0.30 millimeter. An 80-mesh screen is made of No. 40 wire, which is 0.007 inch diameter, the aperture of the screen being 0.0055 inch.

✣✣✣✣

A MINE LOCATOR may start a tunnel on ground outside of his claim for tho purpose of developing his vein in depth, hut the site of the portal of his tunnel must he on unclaimed ground—the puhlic domain—and there must he no intervening claim hetwoen the mouth of his tunnel and his own claim. Should such claim intervene, a satisfactory arrangement must be made with the owner of tbe intervening claim to run the tunuel through his ground.

✣✣✣✣

THE principal danger from electric cables underground is in sending through them teo great a current, thus causing tbe wires to becomo hoated and setting fires to timbers or other woodwork. Where the wires are bare and are used for overhead trolleys, should the person passing along the track chance to come in contact with the wire and his cap be wet he is likely to sustain a severe shock, though usually the voltage is so low in electric mine traction plants as not to render such shock fatal.

✣✣✣✣

THE mineral specimens from Lundy, Mono county, Cal., are: No. 1, quartz-mica-diorite; No. 2, diorito in alteration stage to amphibolite schist; No. 3, an impure mica schist, with much calcium carbonate; No. 4, silicified country rock, probably the quartz-mica-diorite or grano-diorite, with pyrite (iron sulphide); may contain gold and silver; No. 5, similar to No. 4, hut contains more silica (quartz). This rock is essontially a quartz ore, containing about 2% to 3% pyrite, and resembles many California gold-silver ores.

✣✣✣✣

THE United States statutos state plainly that placer locations must conform to the subdivisions of tho land surveys, where such surveys have been made, and for this purpose the tracts may be subdivided into square 10-acre tracts. A 10-acre tract is 660 feet squaro. In regions where Government surveys of the land have never been made placers may be located in any form which may suit the locator providing he does not take more in a single claim than the amount permitted by law—twonty acres. Local laws may require him to take less than this amount.

✣✣✣✣

THERE is no short, "wet" method of determining the presence of nickel and cobalt in pyrrhotite, known to Concentrates. Nearly all processes involve tho employment of hoth dry and wet methods and are more or less elahorate and complicated. If tho ore he at all oxidized naturally, the pale apple-green color of nickol silicate is commonly seen, and in the case of cohalt the beautiful pink color of erythrite, cobalt bloom (hydrous cobalt arsonato), is usually present. The presence of cobalt may he suspected if an arsenical odor is given off when the pyrrhotite is heated.

✣✣✣✣

THE more location of a wator right will not securo the locator. He must, within sixty days from the date of location, hegin activo work of dam and ditch or flume construction, and continue the work until the amount of water claimod has beeu divertod from the stream and is flowing in the canal provided for it. The water must be conveyed to the place for which it is intended and actually used. The ditch or flume must he of a size which will accommodato the amount claimed throughout its entire length. No more water can he claimed than is actually taken and used.

✣✣✣✣

NO EXPERIENCED prospector will condemn a piece of rock on its "looks," for experience has taught that often the most unlikely appoaring rocks are sometimes rich in precious metal. Thus, in Calico district, Cal., a gray or red porphyry was sometimes rich in silver chloride. Jasper and sand rock from the same district were also rich. Many dike rocks carry gold. Quartzites are not infrequently gold hearing, and slates are also sometimes rich in gold. Gold also occurs in calcite at numerous places, and in Amador county, Cal., gold is known to occur in serpentine at a numher of places.

✣✣✣✣

IN the case of relocation for failure to perform assessmeut at Mogollon, N. M.: The right of a locator to make an amended location and to include additional ground, if such may be had, is recognized provided the size of the claim does not exceed the statutory provision or conflict with local laws. B, who takes A's claim for failure to perform the required assessment work or to make the necessary improvements, is within his rights. Having performed the assessment work on his own claim establishos him in his rights in said claim, and he has the right to amend his location, changing the lines if the act does not bring him into conflict with other previously located claims, and he may even give the new claim another name. If A's claim was actually subject to relocation at midnight, Decemher 31st, B is safe and C has no rights in the case at all.

✣✣✣✣

THERE is a difference between tuff and scoria. Tuff is an accumulation of volcanic ejectamenta on land which has heen more or less solidified by rain and surface water. There are several varieties of tuff, viz.: Quartz-porphyry tuff, rhyolite tuff, rhyolite-pumice tuff, trachyte tuff, phonolite tuff, andesite tuff, etc., depending upon the material composing the mass. Scoria is a volcanic rock which is filled with air cells; pumice stone is of this character. When scoriaceous lava subsequently has the gas cavities filled by the infiltration of some mineral such as calcite, silica or zeolite, it is called amygdaloid. There are several varieties of scoria. When the gas cells are few and irregularly distributed the rock is said to be vesicular: when they are numerous and occupy an equal space with solid rock it is scoria, and when the cavities predominate it is pumice.

✣✣✣✣

THERE is a surprising variety in the small details of stamp mill mortars. The original Homestake mortar, placed in the Homestake 80-stamp mill at Lead City in 1878, weighed 5400 pounds. Its dimensions were: Height, 54½ inches; length, 54½ inches; feed opening, beginning 6½ inches below tbe top, 24 inches long, 4½ inches wido and 7 inches deep. At the bottom of tho feed slot, and forming the lip over which the oro passed as it dropped from the feeder, was a projection 4¾ inches wide and 1½ inch thick; the lower edge of the feed lip was 14 inches above tho bottom of the mortar, and 15½ inches from the bottom was the feed opening, which was 48¾ inches wide and 21¾ inches high. The screen frame was set at an anglo of 10 from tho perpendicular. No liners were employed inside the mortars, and no plate on the feed lip, which might he renewed when worn. Since 1878 tho general outlino of the Homestake mortar has been copied, but the liners and other renewable features have since been added.

✣✣✣✣

A FOUNDATION superior to either brick or stone for engines or compressors may be made of concreto. In the selection of materials and in mixing them properly lies success. Tho foundation bolts may be hold firmly in place by upsetting a square head upon the lower end, or tho lower ond may be turnod into an eye. Tho holts occupying positions directly opposite each ether in the foundation may thon be secured hy passing a heavy iron bar, as a piece of railroad iron, horizontally through tho rings at the ends of tho bolts, and the concrete dumped in upon it and thoroughly rammed. When set tho bolts will he found absolutely rigid, if caro he takon to lift the bolts as high as they will go without raising the railroad iron. Mortar bolts may he securod in the same manner, though in the case of wooden mortar hlocks it is advisable to use a har of round iron which may bo driven through a hole of proper sizo borod with a mill auger, the bar, as in tho caso of concrete foundations, passing through tho rings of the holts, the bolts having previously been placed in proper position when tho block was being huilt up of 2-inch planks.

✣✣✣✣

IN some regions of massivo oruptivo or intrusive rocks, where the rocks at tho surface are soft and easily picked or shoveled, the surface is seon strewn with rounded, smooth, hard howldors, of a rock othorwise similar to the decayed rock upon which they rest. This is particularly true of some granite, hut is also noticeable in porphyries, greenstone, etc. This is due to what has been called concentric decomposition, which is a process many massive rocks undergo when subjected to atmospheric or other decomposing agencies, by reason of which the outer portions of an angular block or mass undergo decay, the decomposition advancing from the surface inwardly, the process appearing to develop in the rock a series of concentric layers or shells, one within another, enveloping the nucleus, which is little or not at all altered. In all probability the internal structure of the rock was normally concentric, a condition assumed at the time of cooling from the molten magma, hut which would remain unohserved if it were not for this process of decay. This phenomena in rocks is not uncommon in tho vicinity of veins, and is also noticed in some wide mineral zones. The peculiar howlder-like formation observed in some mines has been erroneously attributod in some instances to the attrition of water, but it is undouhtedly due to decomposition, with results similar to those observed on the bowlder strewn surface. When valuahle ore is present in such veins the ore is found in the shells surrounding tho nucleal bowlders, or in tbe matorial representing tho original outer portions of tbe roundod masses, if all concentric evidence of structure shall be found obliterated.

✣✣✣✣

THE production of alum in the United States in 1902 is reported at about 95,000 short tons. Of this 8500 tons were crystallized alum, tho remainder—a hy product of the manufacture of aluminum in the form of aluminum sulphate. The crystallized alum was valued at $26.25 per ton at place of manufacture, and the sulphate at $22.25. The price in New York City during 1902 was $1.75 per 100 pounds. A large deposit of native alum occurs in the State of Nevada, 12 miles north of Sodaville. The Detroit Chemical Co. of Detroit, Mich., is a manufacturer of alum. Douhtless the alum of New Mexico could he dissolved and recrystallized from the clarified liquor. The output of tin in the United States is confined to shipments of tin stone from South Carolina. Tin is worth at present in New York 28 cents to 29 cents per pound. The tin veins of the Black Hills of South Dakota contain from a fraction of 1% to 20% cassiterite. The mines are not producing, hut in at least two districts are undergoing development. As occurs occasionally in other branches of the mineral industry, the best tin veins were not those first developed in the Black Hills. The ore is not particularly refractory, concentrating readily, although various other minerals of high specific gravity are also separated from the gangue with tho tinstone. Among these are columhite, titanite, wolframite and other rare minerals of similar character. Thore are few, if any, ores too refractory for treatment if the percentage of metal contained be sufficiently large to defray cost of treatment. The tin veins of Cajalco, Riverside county, Cal., contain from a trace of tin up to 90% tin stone. Tho ore occurs irregularly, and the mine development is comparatively small. The works and mines were closed in 1892 hecause the venture did not pay. These mines deserve another trial under more conservative management.

Concrete Hollow Wall Construction.

Written for the' MINING AND SCIENTIFIC PRESS.

The prime consideration in successful concrete work after first-class materials have been secured and competeut mixing aud handling assured, is speedy and uniform drying and drainage. In ordinary wall construction, above ground especially, where the air curreuts, heat aud cold and radiation exert their maximum influence, the exterior or outside surfaces of the work dry readily and quickly, and with the natural tendeucy of good cement work to "float" itself, the surface forms a crust which of course retards the draiuage or drying of the interior portious of the structure. Hence the necessity of covering with sacks or wettiug with hose. In the case of thick bodies like a dam, months are required for even a partial drying, and those who have taken old concrete walls down know that after many years standing in place the interior fracture shows a large percentage of moisture.

In the system of coucrete coustruction discussed herein, as showu iu Fig. 1, the interior of the wall is made hollow by using a uumber of collapsible circular forms placed vertically between outside forms equidistant from the forms and from each other, and after connecting the barbed wire or other forms of continuous binders, which are bedded in the concrete, the outside forms and all around the cylinders are filled with a mixture, in this case six parts coarse gravel and one part best Portland cement, made quite wet as a grout. At suitable intervals old scrap iron is bedded especially near the points where a bond is to be secured. On the end forms, between the large segmental forms, are nailed chamfered cleats vertically and horizontally, which leave the fiuished sectiou 8, 10 or 12 feet, as is determined, dovetailed so that the new sectiou of concrete work is keyed into each succeeding section of wall. In this manner it is possible to withdraw the forms from the green concrete, as shown in Fig. 2, one hour from the time of filling. The draiuage is so effective by reason of the large area of surface exposed to the surface iu each one of these forms, that before the forms are ready to draw there will be from 2 to 6 inches of clear water, and within twenty-four hours the second story may be added. When a boud to old or dry work is to be made, a stronger mixture is used. In this manner have been built 36 or 40 feet of terra cotta lined chimney in a single day and the forms removed the following day. Withiu less than a week the base of the chimney when struck with a top maul will ring like a well seasoned timber or a steel column, showiug that the structure is homogeneous, which is uot always true with a brick flue. In building construction, in addition to its value as a hastener of drying and drainage and the additional fact that it saves one-third in material, is the additional advantage that these hollow spaces, which are continuous, may serve for flues, hot or cold air conduits from furnace or from a cooling chamber, for ventilation, for electric light, telephone or telegraph wires, pneumatic systems, gas and water pipes, etc. Vitrified pipe may be carried into the walls of a structure, the sewage may be thus carried directly instead of into cast iron, and a modern office building may be constructed in this manner at an estimated saving of 40% over present methods.

Fig. 3 illustrates a California tank costing, complete, $900, including four large troughs and floors. Figs. 4, 5 and 6 graphically depict how the same principle is applied in substantial work except that the forms are larger and are placed horizontally instead of vertically. The chief present method of accomplishing this work is to bed steel, cast iron, sewer pipe or wood in a surrouuding wall of concrete or use a wooden form, which can practically be used but once, while these forms may be used an indefiuite number of times. With similar forms J. F. Lyman of Modesto, Cal., to whom we are indebted for the accompanying photos aud data, is building large or small sewer pipe of concrete, either in sections or continuously. The only essentials for this class of work are clean, sharp, coarse, sandy gravel, with or without crushed rock, good cement and one competent concrete man, with ordinary labor. With brick work or stone work, masons and hod carriers demaud $6 and $4 per day for accomplishiug less than may be done with this method in one-half the time and at less cost for labor. Any plasterer can float the walls, or they may be stippled or finished in any way desired in imitation of stone or brick.

The tank shown in Fig. 3 was built for Ora McHenry, on his Bald Eagle ranch, in the center of a 200-acre alfalfa field, which is divided into four fields, the tank, with its troughs and the gates uear, serving as a hub for the field, or four fields, with the dividing fences as spokes. He expects to use this field for a green feed pasture for his large herds of cattle, and his anxiety prompted him to provide this manner of giving his stock plenty of fresh water at all times, and without having them depeud upou ditch water. Plenty of good gravel was available, but it had to be washed, as it held slickeus in quite a large proportion, and the builder considered it unfit for perfect concrete. The engraving shows that the base of the tank is 2 feet under ground and 2 feet above, it is in shape a regular polygon. The walls are 2 feet thick at the base and with an inward batter of 8 inches, leaving the foundatiou walls, upon which the tank proper was built, 16 inches thick on top. In the top of this foundation wall —likewise in two cross walls of even height— was bedded a large amount of scrap iron, projecting above the fiuished top, to serve as an adequate bond between that and the first section of wall above. In the top of each story this process was followed; besides that, sections of barbed wire were wrapped around these projecting irons and carried through the iuside form, converging, like the spokes of a wheel, to the center of the tank, where they were tied together and to other pieces of scrap, all of this uetwork of binders afterwards being bedded thoroughly iu the floor of the finished tauk, the floor itself iu this case being, as indicated, 2 feet above the ground, thus iusuring the use of every gallon of water in the tank. The builder used about five tons of scrap as binders, so that this tank should be earthquake proof. Between the four radiating or intersecting walls aud the outside wall were bedded three barrels of concrete with their tops brought flush with the outer walls. He then filled iu all the space around with well puddled dirt, arching the same between bearings, and upon that tamped the floor, so that with the large amount of binders spoken of in the floor and supported, as shown, at all the points noted, it is immaterial whether the dirt settles or not, for the floor is supported as an arch.

The tauk being 36 feet in diameter, precluded the use of solid forms, so the builder used his flexible outside forms, made by bolting 2x3-inch slats onto a hoop of spring steel, so that by expauding or coutracting these forms a tank iu diameter from 16 feet to a straight wall may be built. The forms being made 8 feet long, enabled him to build with three men two 8-foot segments of the tank, 4 feet 6 inches high, or 16 running feet of 4 feet 6 inches wall, or about 3 yards of concrete material per day. There are about 100 yards in the whole job—troughs, floors and tauk. The work took about thirty days and cost about $9 per cubic yard.

The builder carried the wall around the whole structure, but left an 8-foot section full height out until he had finished the inside walls and floor, when the uncompleted portion was filled and the whole outside cemented with a two-to-one mixture; the tank has a decided echo, much like au iron or wooden one, differing from a brick structure in that it is thoroughly bonded. Mr. McHenry expects to install an electric motor to pump the water into the tauk. In the viaduct or headgate work the excavation is first made 2 feet below the grade of the caual or to good foundatiou, the temporary wooden forms are then placed aud within them the collapsible forms, the concrete is theu tamped around them thoroughly, and after "settling" ten or twelve hours, or over night, the forms are collapsed and withdrawn and is practically finished.

Mr. Lyman says: "I have allowed heavy teams to drive over a bridge three or four days after putting the material iu place, the hollow uature of the structure and the perforated forms insuring instant drainage, large pools of clear water standing at the lower or outlet end."

Fig. 2.—Removing Forms From Hollow Walls.

Fig. 3.—A 65,000-Gallon Tank and Four Water Troughs.

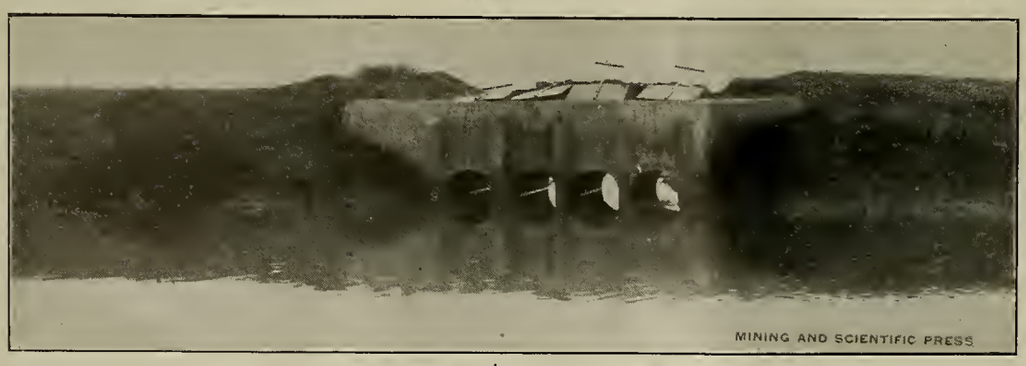

Fig. 5.—Finished Gate; All Concrete.

Grand Encampment District, Wyoming.

TO THE EDITOR:—Through evident inadvertence, the article upon the Encampmeut district in Wyoming in your issue of Jauuary 2, 1904, credits me with a paragraph not to be found in my report upou the region, which is otherwise correctly quoted from Bulletin 213 of the United States Geological Survey. The paragraph referred to is the final one, in which the outcrop and walls of the Ferris-Haggarty veiu are described. The statements which it contains are

inaccurate. My observations upon these points follow:

The outcrop of the vein was originally observed at only one place, where its gossan showed through an otherwise nearly continuous mantle of loose surface debris which has never been cleared away. It is, therefore, not traceable on the surface, and though the two sorts of rock between which the ore body lies do outcrop at points some distance east and west of the mine, neither ore nor any capping which could represent an extension of the vein has been found outside of the actual underground workings of the property. The country rock of the hanging wall is a silvery metamorphic schist, forming a stratum about 80 feet in thickness, while the foot wall rock is a somewhat thicker bed of massive quartzite.

Incidentally, I may be allowed to correct the confusion by your compiler of the Ferris-Haggarty and the Verde mines. The former mine is owned by the North American Copper Co., while the property of the Verde Mining & Milling Co. is still a prospect, though apparently one of some promise.

ARTHUR C. SPENCER,
Geologist U. S. G. S.

Mine Patent Surveys.

TO THE EDITOR:—I have noticed the editorials in the matter of "Mine Patent Surveys" contained in your paper of the 12th of December, 1903, and of the 9th of January, 1904, and thinking the facts upon which the Secretary of the Interior decision was based would interest many and be instructive, I deem it advisable to give a history of the case in the Only Chance and other lode claims.

About July, 1894, the Lucky Strike was surveyed for patent and the boundaries thereof marked on the ground. This claim occupies a portion of the southwest quarter of Section 10 in Township 48 north, Range 1 east, N. M. M. The claim runs northwesterly and southeasterly. The southeast end was tied to a public survey corner of said Section 10. A week or so afterwards the Good Record was surveyed for patent, running in the same general direction, with its northeast corner stake (No. 1) adjoining the southwest corner (No. 3) of said Lucky Strike. The section line between 9 and 10 runs diagonally across the Good Record nearly in the center thereof. The Good Record had a shaft known as the Discovery shaft within 25 feet of its northwest end line, 32 feet deep and well timbered; also a working shaft 4x8 feet in the clear, 71 feet deep, well cribbed, and situated near the middle of the claim. The field notes of this claim show that corner No. 2, the northwest corner, is tied to the said Discovery shaft, and also to the said working shaft. The southwest corner, being corner No. 3, is tied to the Government monument on Ageney Peak and the Government monument on Uneompaghre Peak, two of the most noted mountains in the State, . Likewise corner No. 4, the southeast corner, is tied to those monuments on said peaks. Then corner No. 1 is tied to corner No. 2 of the Lucky Strike survey, and to the Lucky Strike shaft, which shaft was then about 100 feet deep, and is some deeper at preseut, also to the quarter corner of the public survey eommon to and between said Sections 9 and 10, about 1000 feet to the north. Pateuts were issued on the Lucky Strike and Good Record. About two years ago the Only Chance and other lode claims were surveyed for patent, and whieh elaims lie on the north and adjoining the Good Reeord and Lucky Strike. The Only Chance and otber claims were also tied to this quarter corner between Sections 9 and 10, and the Surveyor-Geueral refused to approve of the survey for the reason the public survey tie aforesaid did not agree with the Good Record tie to the same. The surveyor, a very careful and competent man, made a re-survey and still this error oceurred. He also found that this publie survey eorner was off nearly 200 feet to the northeast from the point it should be and the point where the Good Record survey placed it some seven years or more before. He found that all of the Good Record eorner stakes were standing and the other ties meutioned above were correct and there was no conflict actually ou the ground. He reported the facts back to the Surveyor-General and he would not approve of the survey and an appeal was taken to the Commissioner of the Land Departmeut at Washiugton, and the Commissioner sustained the Surveyor-General, then an appeal was taken to the Secretary of the Interior, and he rendered the opinion iu the case of the Only Chance and other lode elaims, April 21, 1903, which you will find in the decision in your land office, I thiuk in Volume 31.

This was au ex-parte affair, and yet the Good Record people were to surreuder the patent, under the decision, upon the written demand by the Only Chauce people, and, upon failure to do so within sixty days, then he would have the Attorney-General institute proceedings in the eourt to cancel the Good Record patent. The Only Chance people served the written notice as advised in the opinion, and the Good Record people told them to commence proceedings at once, for "we would not surrender our patent until ordered by the highest court of the land." That has been some eight months ago, and no suit has been instituted that I am aware of since.

The fact is, that these elaims are situated in a low, barren country, covered here and there with mountain sage, and I was there when the Good Record survey was made, and the surveyor, a chaimnan and myself, found the stone--the quarter section above mentioned—just where we made the Good Record tie. So that, some time within the seven years which elapsed, that stone has been moved some 200 feet to the northeast. The Good Record tie was the first tie that was made to that stone, and the Only Chance and others' survey is the only other tie, the Lucky Strike being tied over to the east.

When the Only Chance people were first in this trouble with the Surveyor-General's office I offered to make three affidavits as to this stone being in place on the line between Seetions 9 and 10, but they would not accept my offer and demanded we make the correction. I met this with the suggestion that we might do that, but how long would it be before we, and even the Only Chance, would be called upon to surrender our patents again in ease this same stone would assume its somnambulistie tendeney by the time another patent survey was made on some other claim? If they would assure us this ubiquitous stone would remain in place forever, we would correct that tie.

As you say, this whole matter will require only a wonderful system of "book-keeping" ou the part of the land department of the United States. It cannot imperil a mau's title to a pateuted claim whieh has its boundaries thoroughly marked aud established upon the ground, still with such an anomalous deeision of the Interior Department many persons will have their patented elaims clouded with another patent from the United States for the same ground, and, by all means, we should have, as you suggest, a "Cabinet Departmeut of Mines" established at Washington.

Another remarkable case in this eounty has come to my knowledge and practiee, aud that was in the ease of the Volunteer lode and the Pierpont lode. The Volunteer lode was patented about 1882. It is situated in heavy timber lands and each eorner of the patent survey was tied to bearing trees, and three of them to large and deep working shafts, one eorner to the quarter corner of section, and two on the south. This claim was worked for many years and beeame renowned for its rich ores, and possibly several hundred thousand dollars worth of ore was taken out. It has been eonveyed as many as a half dozen times. The boundary stakes have been kept in their origiual positiou and the bearing trees are still standing. In this vicinity there have been several excitements sinee this elaim was patented, and, in consequeuee thereof, this quarter corner oceupied several different positions as time went on, until the surveyors in surveys made during the last fifteen years abandoned it as a tie and in their surveys adopted as the loeal tie the uortheast quarter coruer of this section, and when the Pierpont lode was located, and ever since, this south quarter eorner has left the vicinity entirely—at least, it cannot be found.

About two years ago the Pierpont locators came along, when the owner of the Volunteer was absent, and set their location stake within the boundaries of the Volunteer's ground, and there sunk their discovery sbaft to about 12 feet, surveyed and recorded the said Pierpont lode, taking in the Volunteer shafts and about two-thirds of the Volunteer surface ground. Without doing any more work or improvements, the Pierpont made its pateut survey and applied for patent. This patent survey was tied to the aforesaid northeast corner of the section. The owner of the Volunteer came to me while the notiee was being published for patent on the Pierpont, and I told him he might apply for injunction, bring his suit in ejectment, enter a protest, but in no event could they take away his rights to the ground of the Voluuteer, and his claim, being a patented claim, an adverse could not be sustained against him. As the Pierpont discovery shaft was uot on the public domain, and it being clear that they had not done the $500 of work (nor have they done it since) on the Pierpont, they were not only clouding his title, but were practicing fraud upon the Government. So, for the time being, we filed a protest, accompanied with affidavits, setting out the facts in detail about the Pierpout aud the Volunteer, as above indieated, presuming that the department at Washington would inquire into the facts, and the whole matter was certified up to the Commissioner and he sent the case back to the local land office here with a letter of instructious that the Pierpont people should be allowed to enter their claim, and that the Volunteer should have entered its adverse within the sixty days, and the result was, the Pierpont patent has been issued and the Government of the United States has sold and giveu patents, conveying the fee simple title to about six acres of land to two claimants, to wit: the Volunteer owners and the Pierpont owners. Here the department's attention was called not only to its patent issued about twenty years ago for this land, but the fraud that was being practiced upon the Government and the great injustice upon the Volunteer owner in clouding his title, by sworn proofs and plats. I understand the Volunteer has instituted suit against the Pierpont in the District Court of the United States at Denver. J. M. McDOUGAL.

Guuuison, Colo., Jan. 18, 1904.

Mining Problems in Colorado.

Written for the MINING AND SCIENTIFIC PRESS by PERCY A. LEONARD.

Closely associated with the technical problems in mining that are being so skilfully and persisteutly attacked by the brilliant staff of American mining engineers, are those which must be reached on the strictly economic side. In this field layman and alumnus alike contend.

In short, the last analysis to which the most careful investigator along technical lines must submit in obedience to the commereialism of this age is, will it pay?

Praetical mining is not unique by any means in demanding, as a eondition of success, good business management, prime factors in the equation of which are skill and honesty. It is not an uncommon experienee to find expensive equipment, ineluding dressing and reduction works, relegated to the scrap heap, largely because of the lack of economic common sense or honesty on the part of the manager.

Since the time, about forty years ago, when the late Senator N. P. Hill of Denver successfully attaeked and solved the metallurgical problem presented in the reduction of the sulphide ores of Gilpin county, persistent investigation along these lines has developed what we arbitrarily term, "The Proeess Man." While his eoming and labors have resulted in distinct advauces along the technical lines, mining practice has not been always correspoudingly beuefited in a strictly business way. There are a few camps, like Leadville and Cripple Creek, where the mining operators have aggressively evolved, almost co-ordinately, suceessful mining practiee in its most complex form, whieh includes eeonomic milling.

The sequela of this evolution are a constaut and growiug appropriation and utilization of phenomeually low grades of ore, both simple and complex in character, and an increased interest in miniug investments.

While all milling and smelting practice, like every other form of scientifie research, is empirical to a degree, yet euough of economic value has resulted, so that certain proeesses are universally accepted as standard, beeause of their dividend-producing eharacteristics.

It is ouly ueeessary to enumerate a few of these to illustrate this contention. Among these may be named stamp milling aud amalgamation, cyanide in association with eoneentration, ehlorination, magnetic zinc separation, blast, lead smelting, pyritic and mattiug furnace practice.

It is a far cry from the old lead furnace of 1878, that operated exelusively on the surface lead carbouates, found on Carbonate, Fryer and adjacent hills, to the maguificeut smeltiug plant of the American Smelting Co., now operating in Leadville on all elasses of sulphide ores.

This evolution is au epitome of a quarter of a century's careful research, and has almost immeasurably wideued the scope of both smelting and mill practice throughout the miuing world. It has made of mining a high-grade mauufacturing industry by utilizing what, eveu withiu tbe last five years, has been eonsidered waste material, and has made active and dividend-producing miues of undeveloped properties in many ueglected aud abaudoned districts.

The marked advances in cyanide practice, as modified aud adapted to the various ores, has beeome of world-wide uotoriety by such illustrious examples among the dividend earners as the Homestake, Treadwell, Mercur and scores of others, operating on what teu years ago would hardly be eonsidered a good quality of eountry rock.

But at this auspicious time, when the technical diffieulties have been largely subdued, an economic complication presents itself in the appearauce of the destructive and unreasonable miuers' union.

Contemporaneously with the growth of the triumphs of the mine operators in overcoming the physical and other economic obstacles incident to the present development of the miuing industry, the labor boss, or walking delegate, has been evolved.

If he were a man honestly attacking the problem of the relation of capital aud labor in its true eeouomic aspect, he would be hailed with cordiality by every mine owner and smelter man in the United States.

But it is his utter disregard of this phase of the question and the exaggeratiou of the purely personal equation that makes him dangerous and un-Americau. The main issue to-day is not so much between labor and capital as it is betweeu the labor boss and the man who wants to work for whom he pleases at whatever schedule of wages he desires, irrespective of his connection with any organization, and with perfect freedom from molestation from any man. Miniug, as a whole, is less affected than other industries, and yet the disasters threatened and incurred have so sharply defined the issue in the battle now on between operators and employes that the most casual observer can understaud that it is to be a decisive struggle.

The opinion is quite prevalent among the better informed who are on the battleground that the ultimate result will be greater independeuce, possi-

bly lower wages for miners, and greater activity in development and ore production.

It is also believed that the fight will be over sooner in the mining sections than in other portions of the industrial world, and hence, while unfavorable economic conditions may obtain in the East, the Western mining fields will be enjoying an unparalleled era of prosperity.

Automatic Ore Sampling.

Written for the MINING AND SCIENTIFIC PRESS by ALFRED HARVEY, E. M.

The following description is that of an automatic ore sampling plant, illustrated by line drawings. In the drawings the aim has been to give the machinery prominence, hence the building construction and framing has been omitted as far as possible.

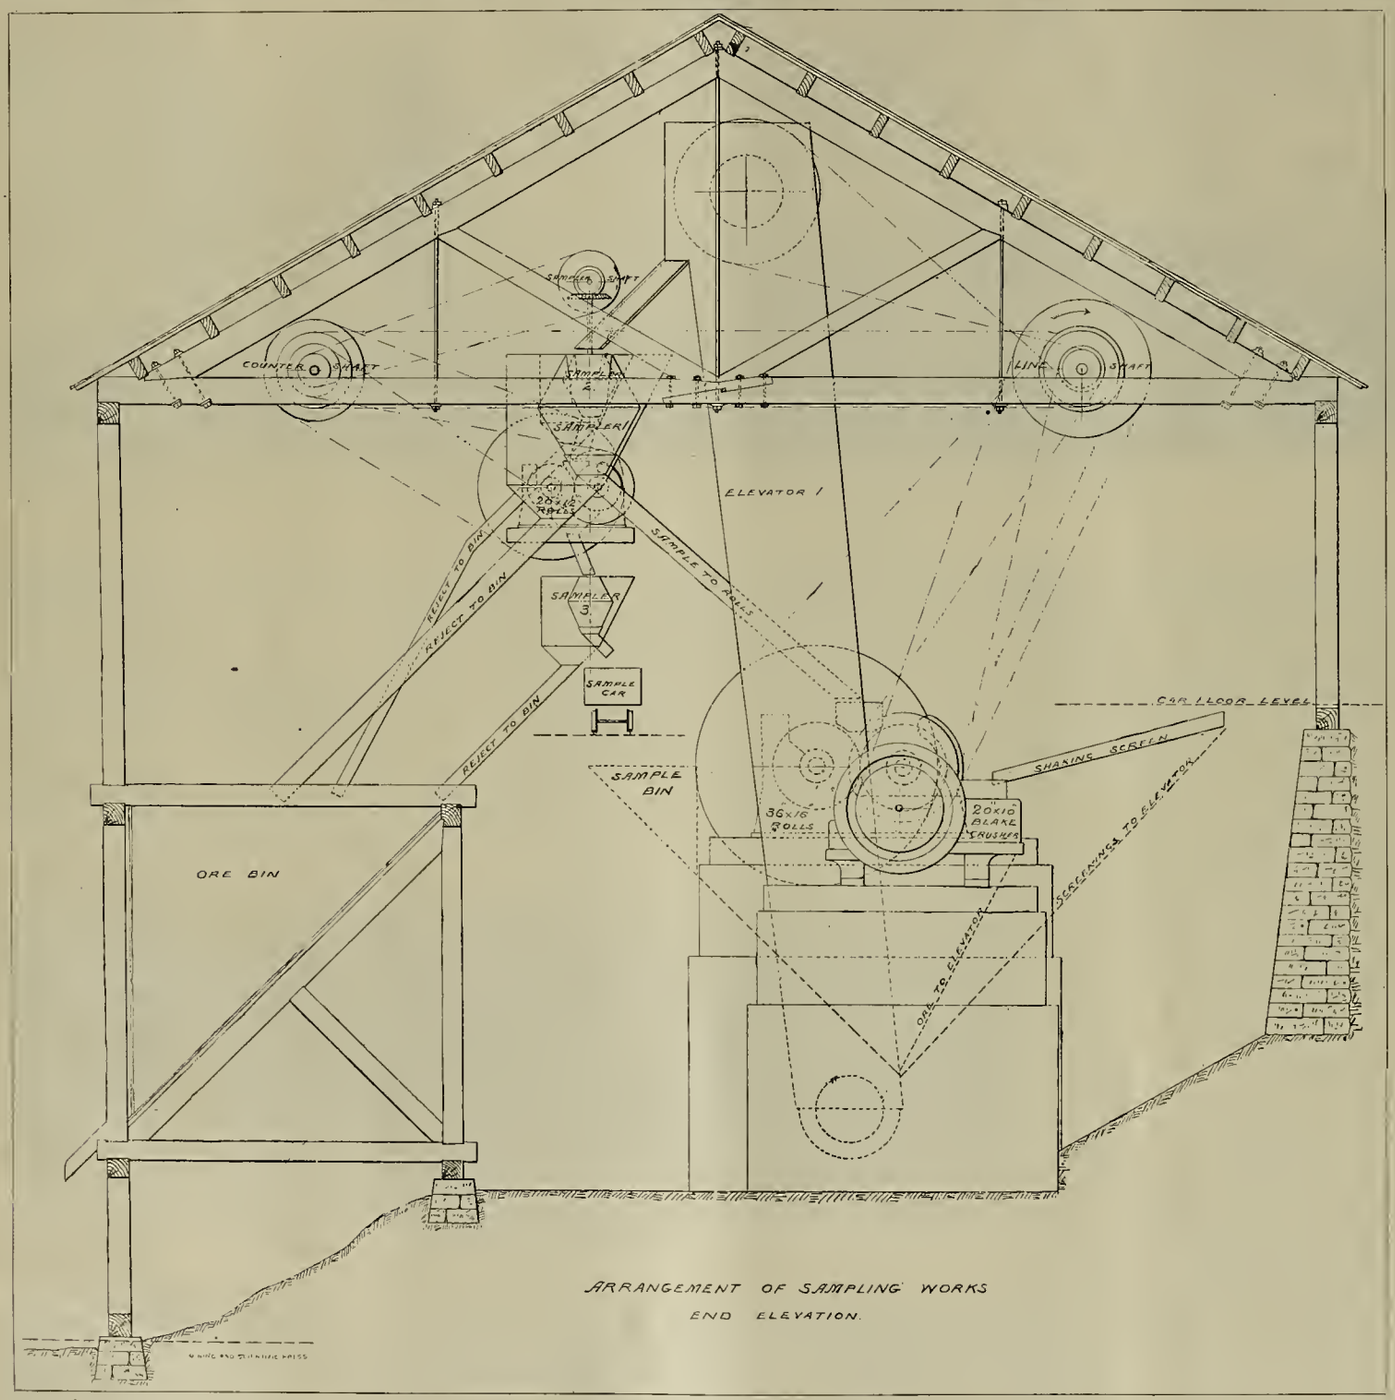
The object of the design is to take a correct sample with the least possible crushing of the ore. Say, for instance, for direct smelting ore.

The plant consists of one 20″ x 10″ Blake crusher, one pair 36″ x 16″ rolls, one pair 20″ x 12″ rolls, two cup elevators, three sampling machines, shaking screen, pulleys and shafting, ore bins, etc.

The capacity of the plant will much depend upon the character of the ore being crushed, and the size of the pieces to which the jaws of the crusher are set to break. We will assume 300 tons to be the daily capacity of the plant.

The samplers shown are intended to cut out one-tenth at each revolution, but they are also made to take one-fifth, one-eighth, one-sixteenth, etc., as circumstances may require.

The manner of operation is as follows: The ore from the car floor level is dumped upon the shaking screen, which feeds the oversize to the 20″ x 10″ crusher, the crushed ore passing to elevator 1, the screenings being conveyed to the same elevator. This elevator discharges all the ore over sampler 1, which cuts out one-tenth as a sample, or thirty tons, which passes through the spout to the 36″ x 16″ rolls to be recrushed. The rejected ore from the sampler, or nine-tenths of the original, is passed on to the storage bins. The one-tenth after recrushing goes into elevator 2, and is discharged over sampler 2, which takes out one-tenth and conveys it to the 20″ x 12″ rolls to be recrushed, the reject passing to the storage bins. The second one-tenth, or one-hundredth of the original ore, having been recrushed as far as possible, is discharged over sampler 3, which cuts out one-tenth. The sample is now one one-thousandth part of the original ore, or 600 pounds, which is discharged into the sample car. The reject, as from the other samples, goes to the storage bins. If the 600-pound sample is considered fine enough it can be dumped over Jones' riffle samplers, arranged in a series of three, with two baffle plates, which would cut it down to 75 pounds. Or it can be raised by a platform hoist and dumped as often as desired to get a suitable quantity for the sample grinders which follow. If, however, it is not thought safe to cut down so far without further comminution, the sample can be dumped into the sample bin, shown in dotted lines, and after the elevator and rolls have been cleaned the sample is allowed to run from this bin into elevator 2. Sampler 2 is thrown out of gear, so that it will not revolve, and the scoop is carefully placed under the elevator spout in such a manner that no waste can take place, and the sample is run through this machine and into the 20″ x 12″ rolls, where it is crushed finer and discharged over sampler 3. If this machine (sampler 3) has another scoop put on for the occasion one-fifth can be cut out, or 120 pounds, which can be subdivided on the riffles before going to the sample grinders; or the one-tenth can be taken, as those in charge may wish, the reject as usual going to the storage bins. After the sample has been reduced to a fine powder by the grinders it goes through the assay office in the usual way.



Arrangement of Sampling Works, End Elevation.

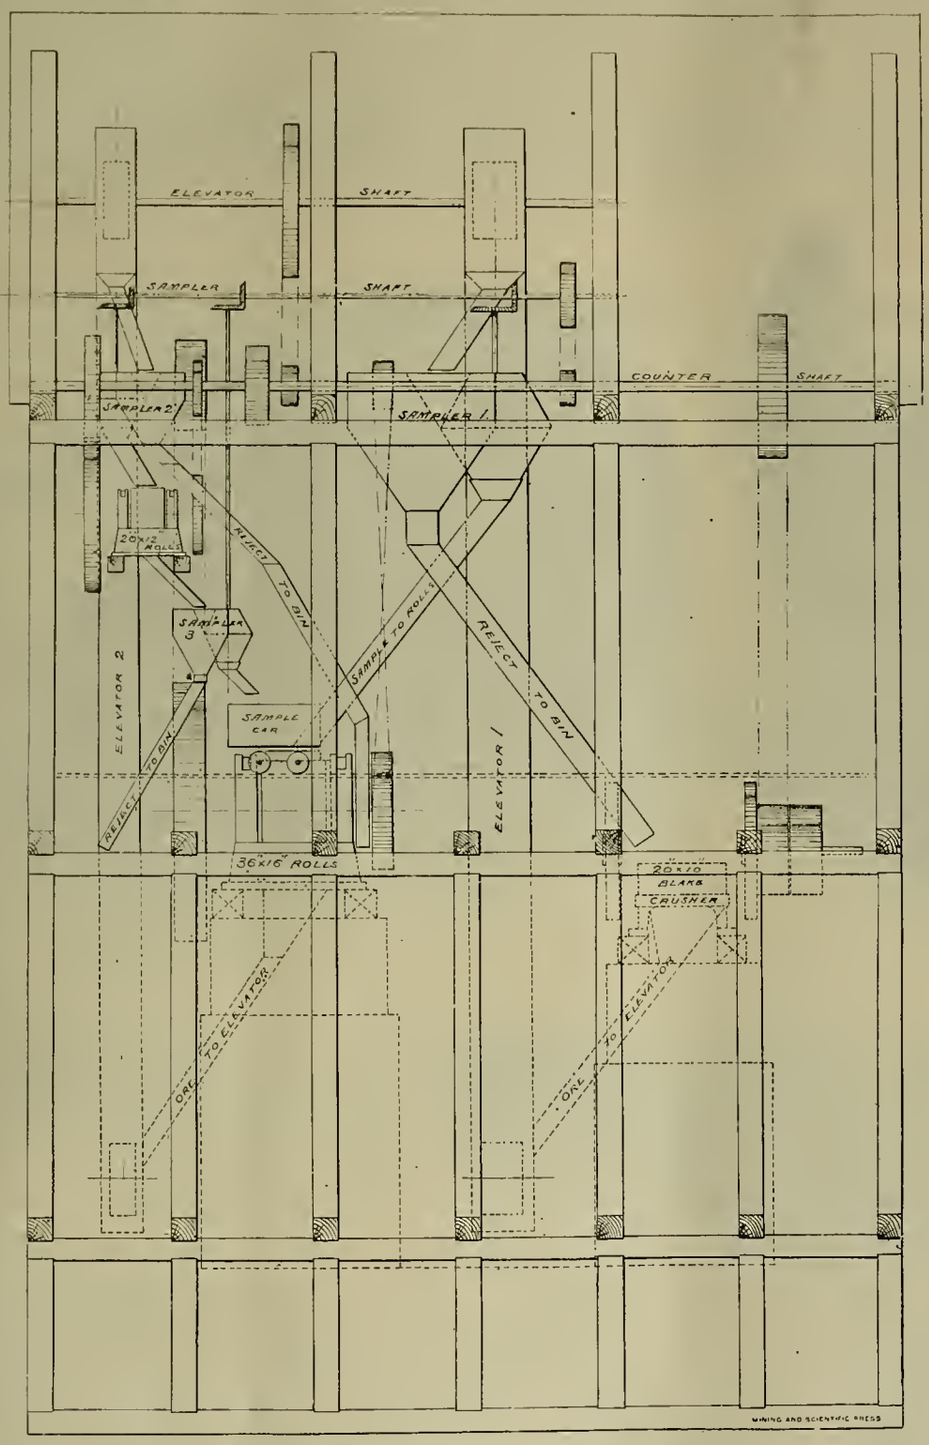
Of the few machines which will sample correctly and which stand out prominently in reduction works in Colorado, the best known to the writer are the new Brunton and the Vezin samplers. In the drawings the latter are shown. Both these cut out the whole of the ore stream at stated intervals of time, as a sample, in distinction to those machines, which take part of the ore stream all the time. Each of the Vezin samplers shown has one scoop, and by the speeds adopted No. 1 sampler would take a scoopful every 4 seconds, No. 2 every 3 seconds and No. 3 every 2.2 seconds. The section of the slice cut out of the stream of ore would be a parallelogram.

The inclined spouts from the elevators tend to equalize and compact the ore streams before discharging them over the samplers.

The plane of the center line of the stream of ore

forms a tangent to the circle described by the center of the receiving part of the scoop. In this way there is no wear on any part of the sampler, except the scoop itself. At the same time the arrangement is such that the ore cannot pound against the cone, neither can it adhere to the inclined end of the scoop, if of a sticky nature.

These samples are suitable for sampling anything from the finest ore up to coarse stuff, say, passing a 4″ ring, or larger. Conditions may be such that it is not considered advisable to pass a certain lot of ore through the Blake crusher, as it may be already fine enough. It may also be desirable to cut out one-fifth instead of one-tenth. In this case a second scoop can be attached to each sampler. The ore would all pass to elevator 1 through a spout for that purpose, avoiding the shaking screen which feeds the crusher.



Automatic Sampling Works—Front View.

Assuming the quantity of ore in this lot to be 300 tons the resulting sample will be 2.4 tons. This sample would be collected in the sample bin until the sampling of the original lot of ore had been completed. After cleaning elevator and rolls it would be fed into elevator 2, discharged over sampler 2, then recrushed in 20″ x 12″ rolls, discharged over sampler 3, giving a sample of 192 pounds, which is probably fine enough to be cut down to the desired size by the riffles before going to the riffles.

The elevator boots being of the drop bottom type can be conveniently cleaned and the riffle samplers can be brushed out without moving them. The rejected portion from the riffles falls into a small bin and can be removed when convenient. A Dodge crusher could be in place of the 36″ x 16″ rolls.

Modifications of this plant can be used to suit conditions at any place, or where the ore is received in smaller lots. The proportion between the amount of the sample and the maximum size of the pieces is a matter that requires consideration. Much depends upon the nature of the ore, whether it is rich or poor, and also whether the value is uniformly distributed. If a sample which has been crushed sufficiently fine to pass through a screen with openings of 1 m.m., can be cut to one ounce avoirdupois, the following weights would be the least that could be taken with safety, if the pieces are of the sizes given:

Diameter of Largest Pieces—M.M.	Diameter of Largest Pieces—Inches (Approximate).	Minimum Weight of Sample.
1	2/5	1 ounce
2	1/2	½ pound
4	1	4 pounds
8	2	32 pounds
16	3	256 pounds
32	1¼	2,048 pounds
64	2½	16,384 pounds
..	3½	44,958 pounds
..	4	69,109 pounds
..	5½	79,300 pounds

Where the ore is required to be finer than that for which this design is intended, for milling purposes, for instance, then one elevator would be needed (dispensing with No. 2), which would discharge into a revolving screen. The screenings which would pass ½″ to ⅝″ ring would pass into the screen hopper, then over a sampler, which cuts out its sample and discharges it into an intermediate revolving mixer. This mixer changes the intermittent into a continuous stream of ore, and then discharges it over a second sampler. The sample is allowed to fall upon a shaking shoe feeding a pair of 20″ x 12″ rolls, recrushed and discharged over sampler 3, the reject being conveyed to the storage bins. The oversize from the revolving screen is passed through a suitable spout to the 36″ x 16″ rolls, recrushed and discharged again into the elevator and again raised to the screen. This process would continue until all the ore had passed through the screen and had been sampled. In such a case the jaws of the 20″ x 10″ crusher would be set closer.

If one-eighth is cut out by each sampler and original weight of ore was 300 tons, the resulting sample would be about 1170 pounds, and would probably be fine enough to cut down further by means of rifles. But if not considered fine enough it could be again fed into the 20″ x 12″ rolls and sampled as before, giving about 186 pounds as a sample.

Remarkably close results are obtained in Colorado by automatic sampling. Ore received at one of the large custom mills, which assayed from $200 to $300 per ton, checked within .02 ounce, or say 40 cents per ton, by this method of sampling. The cost of sampling at these works was 12 cents per ton. One would expect to find more mines, which operate their own mills, automatically sampling the ore coming in and the tailings going out of their mills, thus having a good check on their saving and of the value of the ore from the mine.

Mine Patent Litigation Discussed.

At the request of the Colorado Mine Operators' Association and the Denver Chamber of Commerce the committee appointed by President Roosevelt, consisting of F. H. Newell and G. Pinchot, chiefs of bureaus, spent most of the 22d inst. in conference with some Colorado mining men and lawyers. The purpose of this committee being to report upon the practical operation of the land laws in the West, the subject of the recent rulings of the Land Department as to mineral patents was thoroughly discussed. It was clearly shown by practical illustrations and by the presentation of many specific rulings that the department is committed to the policy of determining the position of patented mining claims by a technical interpretation of the patent description, and that it is refusing to be governed in any manner by the official monuments which identify the claim upon the ground. The committee was furnished with certified diagrams taken from the records of the departments, showing that the lands segregated were in no sense the lands occupied by the claims upon the ground. It was shown that multitudinous complications are being wrought under the present practice; that much land is being segregated which is not patented; that much land which is patented would be thrown open to location and acquisition if the ruling of the Land Department were upheld by the Federal courts; that conflicting claims are piled (on paper) on each other in the Land Office maps, though in some instances they are actually from ½ mile to 2 miles apart. The evidence presented was a revelation to the committee, which expressed itself as not unfamiliar with the question, but as being surprised at the situation as stated. G. L. Hodges opened the subject with a statement of the feeling of insecurity which pervaded the country as to the matter of primordial mining titles, owing to the decisions referred to. G. R. De-Nise presented illustrations based upon certified records of the Land Department, showing the practical effect of the rulings. J. Fillius dwelt upon the fundamental principles of law which were being trampled upon by giving courses and distances preference over monuments. W. V. Hodges gave a synopsis of the Groves test case which is being brought by the Colorado Mine Operators' Association, for the purpose of correcting the practice of the department. M. Boehmer spoke upon the disastrous effect upon the integrity of the engineers and of the records of the Government. A. W. Warwick treated the matter from a wider standpoint than the mere interests of Colorado, stating that Montana, Arizona and many other States were equally interested and would suffer as materially as Colorado. L. F. Twitchell presented the cases which have been recently decided which tend to fix the rule as it now stands, and the necessity for common action in the matter. E. C. Stimson treated the matter in its general bearing upon the mining industry, stating that the mining industry would be seriously retarded unless the matter is speedily corrected. In conclusion, W. E. Pasmore, secretary of the Colorado Mine Operators' Association, spoke on behalf of that organization, and W. F. R. Mills spoke on behalf of the Denver Chamber of Commerce.

STRIKE, DIP AND PITCH OR TREND are common terms in mining. Strike is the horizontal direction of the vein, and dip is a direction downward on the vein at right angles to the strike. "Pitch" or "trend" usually refers to the ore shoot, and has reference to the downward direction of the ore body along the strike of the vein.

The Electric Reduction of Gold From Cyanide Solutions.

Written for the MINING AND SCIENTIFIC PRESS by A. A. BEADLE.

The problems presented iu the metallurgy of gold are somewhat different in their very essence to those belonging to any of the other metals. First of all the metal is found almost exclusively in its native state aud requires no reduction; secondly, the purification of the gold when once extracted entails a cost quite insignificaut in comparison to the value of the metal. Geuerally speaking the ouly problem in the metallurgy of gold is the collecting of the extremely fiuely divided particles which are disseminated through the body of a largely preponderating matrix of quartose or silicate rock. In the treatment of free milling and of alluvial ores amalgamation and chlorination serve to extract the bulk of the gold, the former depending upon the gold particles being absolutely free, and the latter dissolving all metal exposed to the action of the chlorine. Once having obtained the gold in solution in the form of chloride the operation of extractiug it from this solution is a sim ple aud inexpensive matter, and there is uo object iu attempting to recover either the chlorine or the precipitatiug ageut, and there is therefore no reason to believe that electricity will ever be called in to perform this operation.

The case is, however, somewhat diffcrent with the treatment of refractory ores or those which have withheld the last traces of their gold from the amalgamation plates. These ores are amenable to treatment by the cyauide method and have to be lixiviated with a solution of potassium cyanide in order to reuder the metal solnble. In this process electricity, although uot pretending to be essential, has nevertheless stepped in aud promises to overcome some of its weaknesses.

If au ordinary gold ore, containing a reasonable amount of gold and very little cyanicide, be taken as an example, a very weak solution of cyanide, indeed, is theoretically required to dissolve the gold and satisfy the ordiuary equation, say about 0.005% or less, but in practice it is found necessary to nse solutions of about 100 times this streugth. A solution of about ten times this strength will, uuder ordinary circnmstances, dissolve the gold, but it might take somewhat longer. This, however, is not of snfficient strength to enable the metallic zinc, which is subsequently used to reduce the gold from solution, to do its work efficiently, and for this reason alone a much more concentrated solutiou is required, i. e., about 0.5%.

If electrical reduction be adopted in the place of the ordinary zinc methods, the only limitiug factor to the dilution of the cyanide solution is the strength required to dissolve the gold. This, theu, is governed by the length of time which it is most advautageous to allow the dissolviug process to take aud is not dependent on the weaknesses of the zinc extraction afterwards. If the ziuc method of precipitation be used the zinc goes into solution and throws o ut the gold. If the reaction were to take place according to theoretical cousiderations oue ounce of ziuc would throw down abont six ounces of gold, producing a double cyanide of zinc and potassium, but zinc is itself capable of dissolving in potassium cyanide, so that much more zinc potassium cyanidc is produced thau the above principles would snggest, with the resnlt that the bulk of the cyanide is destroyed by the zinc and the dissolving power of the solution much impaired.

Since electrical reduction enables a weaker solution of potassium cyauide to be made nse of, it is obvions that the loss of cyauide is somewhat less, and if the metal can be extracted without decomposition of the cyauide or converting it iuto another double cyanide with some other base metal, the loss might be reduced to a minimum.

The present methods for the electrical reduction of gold cousist in passing the liquid in a slow, bnt continuous stream between a series of electrodes, so that during its passage the whole of the gold is brought into contact with the cathode and there deposited at a very low cnrrent deusity. This idea is best represented by the Siemens–Halske process which is coming iuto nse in South Africa, New Zealand and elsewhere. In this the cyauide solution is allowed to flow slowly between iron anodes and lead cathodes, which are afterwards cupelled for the recovery of the gold. These electrodes are so arranged as to form a series of "baffle partitions," necessitating the circnlation of the liquid through the whole series. The cnrrent density at which the deposition should be conducted varies greatly with different authorities, from 0.05 to 5.00 amperes per square foot of cathode snrface, bnt the former limit is, in all probability, the most advantageous, especially in the treatment of weak solutions, containing about 2 dwts. per tou. There is a certaiu small loss of cyanide due to the decomposition which takes place at the surface of the iron anodes, but this is converted into Prussian blue and can be collected aud afterwards converted into cyanide. The slight loss is made up with new cyanide before returning the solution to the leaching vat.

It is easy to see then that the chief advantage in the electrical reductiou over the ordinary zinc precipitation of gold is embodied in the saving of cyanide, for it is claimed on some authority that the cost of cyanide to be made np in the former is only about one-third of that in the latter, aud the total cost of working the extraction throughout is thereby very materially decreased. The laboratory tests for this method are to a great exteut the same as usual—the cyauide requires to be carefully and accurately estimated in order that the cyanide solution may be carefully adjusted to as low a percentage as possible without the danger of beiug eutirely destroyed during the somewhat lengthy period of leaching the ore.

It is somewhat difficult to obtain authenticated figures which show a fair comparisou between the two methods of extraction, but the following gives an estimate by A. von Geruet of the cost of working the electrical method on the Rand:

	Price Per Ton of Ore Treated.
Cyanide	$0.07
Filling	.20
Fuel, power, lime, lead, iron	.15
Labor, native and white	.14
Charge due to extra cost of plant	.01
Stores and general expense	.07
Total	$0.62

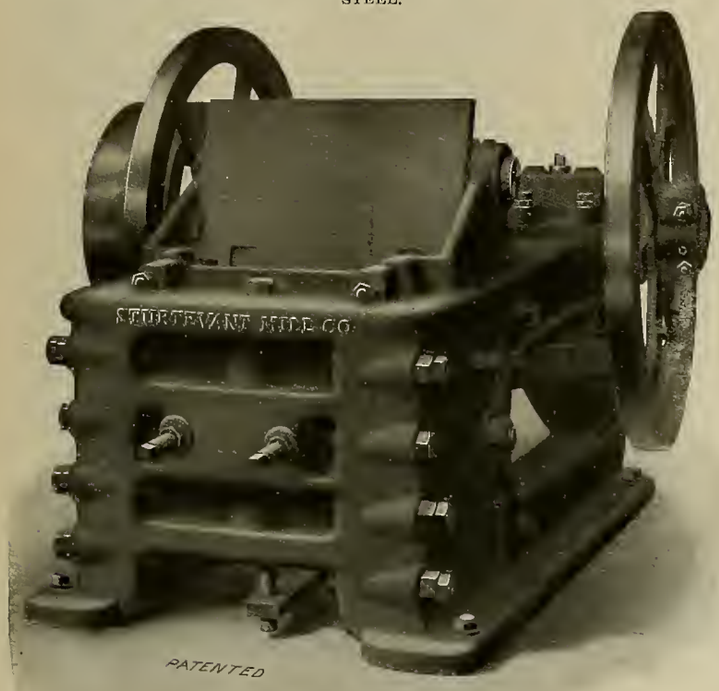
Another authority at Witwatersraud in a similar estimate makes it 70 cents per ton of ore treated.

New Design Roll Jaw Crushers.

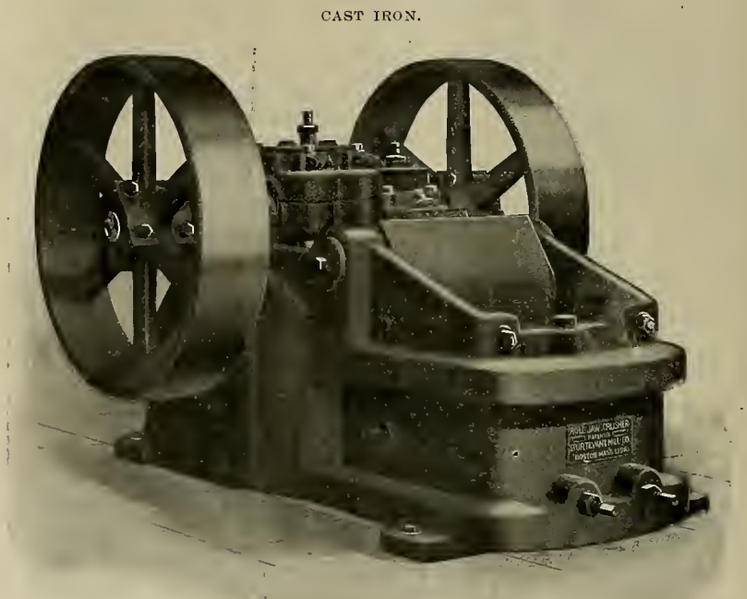
In the accompauying illnstratious are shown two new designs of the roll jaw fine crnshers, one of cast iron and the other of sectional steel construction. Of these, the manufacturers say: "The former is remarkable for its compact, simple and massive design. It is heavy, low and immensely strong, yet all of the reciprocatiug parts are steel, the comparative lightness of which greatly reduces vibrations."

The steel sectional roll jaw crusher is also of unusual strength, although comparatively light, its steel parts being stronger than cast iron, although weighing much less. Both of these machines and several others are shown and described in the new catalogue (No. 8) just issued by the Sturtevant Mill Co. of Boston, Mass. These roll jaw crushers are not complicated. They are jaw and toggle machines of the Blake type, and are designed to be unusually capable of a fine grade of output. The jaws, instead of advaucing and receding, are intended to always remain the same distance apart, and are thus iutended to deliver a fine aud uniform product such as would come from an ordinary crusher and two sets of rolls. They do uot clog and the arrangement of parts admit of a fine class of work. Jaw and toggle crushing is a cheap method of hard rock reduction, and, where roll jaw breakers can crush large rock, their advantage in producing a fine output from large ore is manifest.

STEEL.



CAST IRON.



New Design Roll Jaw Fine Crushers.

Vajen Head Protector.

Frequent reports of mine fires indicate the need of some protection to those involved therein, whether in the mine at the time or engaged in an effort to save life. Such protection is suggested in the use of a helmet or head protector, by the use of which a man can face thick smoke and deadly gas with no danger of suffocation, he being supplied by the helmet covering his head with air sufficient for respiration for two hours. The manufacturers furnish testimonials from miue superiuteudents and others who found them of great value in the rescue of miners overcome by smoke, gas and fumes caused by underground fires. Anything that tends to lessen danger is worthy of notc, and from the statements and testimonials it would seem advisable for any mine superintendent or foreman to have at least one of these helmets on hand for instant use when needed. No one knows when such a protection may be wanted, and the time to get one is before the dreaded accident occnrs. These helmets are made and furuished by thc Vajen-Bader Co., Richmond, Ind., who will send full particulars on request.

ARTIFICIAL ORNAMENTAL STONE may be made by mixing colored cement iu any desired tints and pouring the mixture iuto a bottomless shallow box, set upon a glass plate. After the cement has been poured into the box it is stirred to a greater or less extent, producing those pleasiug combinations of color seen iu artificial stone.

Underground Handling and Transport of Ore.*

Written by CHARLES B. SANER and GEORGE CARTER.

The conveyance of the broken ore from the working face in a mine to the shaft is one of the most important questions of mining and demands careful consideration and attention, whether done by manual, animal or mechanical power, and we believe there is still further scope for improvement in the systems at present in use, both for more expeditious as well as cheaper methods of handling and transporting ore underground.

In dealing with this subject it is desirable to first mention the various methods which have been and are still being used to effect underground transportation by means of such appliances as baskets, leather bags, hand barrows, sleighs, etc., which, although not applicable to mining practice on the Rand, are mentioned to illustrate the methods of handling ore in use at the present day, up to the gradual evolution of the efficient mechanical appliances on a well-equipped mine.

H. H. Webb, in his address to the South African Association of Engineers in June, 1903, stated "that the comparison of working expenses for the year 1902 shows that from 55% to 60% of these costs were in actual mining itself underground, and it is here that the chief economies are to be looked for in the future. At the present cost of milling and cyaniding there is little margin for reduction." And out of this 55% to 60% quoted above, about 15% before the war and 20% since the war is expended on underground shoveling and tramming.

A good deal can be learned from coal mining practice of recent years, where the use of mechanical appliances for mineral transport has made great progress and materially lessened the cost of production, and the application of some of these principles to the varying conditions which exist in metalliferous mining might be attended with economy, especially in the saving of time, as the time factor is one which enters so largely into all the operations conducted on these fields.

We propose to deal with this subject under the following headings:

1. Conveying of the broken ore to levels.
2. Transport of ore to shaft loading stations.

CONVEYING OF THE BROKEN ORE TO LEVELS.—In many of the outcrop mines, especially in the upper levels, the reef dips at such a steep angle that the ore, when broken, easily finds its way to the boxes and ore chutes by gravity, with little or no assistance, hence it is only comparatively recently that, with the general flattening of the reefs in the deep levels and consequent increased "backs," owing to the levels being set off at approximately the same vertical height, this subject has assumed greater importance.

In the first place, a great deal depends on the condition of the foot wall of the stope and the amount of moisture in the broken rock.

The broken ore from the stope faces has first to be handled by shoveling, the poorest and least capable "boys" being utilized.

They laboriously scrape, shove or throw the rock slowly down the stope, and one often finds them huddled together, moving the ore only a few feet at a time, and as often as not by a circuitous route. An improvement is sometimes effected on this crude means of handling the ore by the employment of sheet iron or other suitable material as a temporary floor to the stope.

In place of conveying the ore entirely by this under the rails of the main incline plane and necessitate a break in the track, which is bridged over by movable rails when it is desired to work from a point above.

The only mechanism required to work this device consists of a reel, sheave or drum, around which a rope is passed one or more turns, each end of which is connected, respectively, with a loaded and empty truck, or, when drums are used, two ropes coiling in opposite directions.

The necessary control is obtained by a brake, which is either a segment of wood or a steel band arranged to bear on the periphery of the sheave or drum, or by rubbing discs acting on the boss of the pulley controlled by a tightening bolt.

The rapidity with which the descent can be made largely compensates for any delays that may occur at the top or bottom of the incline, and, owing to the small amount of labor required—that is, one man or "boy" at the brake, the economy over shoveling by hand over long distances is obvious. At the bottom of the incline further handling is carried out either by allowing the contents of the trucks, especially adapted for narrow stopes, to be dumped into an ore chute or box, or, if the stopes are of sufficient width, to allow of the main drive trucks to be used. They may be run direct onto a flat sheet, turntable, or curve, as may be found most expedient.

In the first case the incline can be kept continuously running with intermittent tramming from the box, but the second necessitates a continuous supply of empty trucks.

In the case of the latter method, in use on the Nourse Deep, Ltd. (see Figs. 1 and 2), using 16 cubic foot trucks, the wire used is ¾ inch diameter, the length of the incline being 250 feet, average dip 30°, weight of rails used 16 pounds.

In this case the jig wheel or sheave is composed of two ¾-inch circular discs of steel plate 2 feet 6 inches in diameter, bolted together and flanged round the periphery to a depth of 2½ inches, tapering from nothing to 1½ inch, with rubbing discs placed on either side, the braking being effected by a tightening lever, acting by means of a nut on a square-threaded bolt passed through the center of the discs, the rope being only passed round this sheave once. Its life is thereby considerably increased.

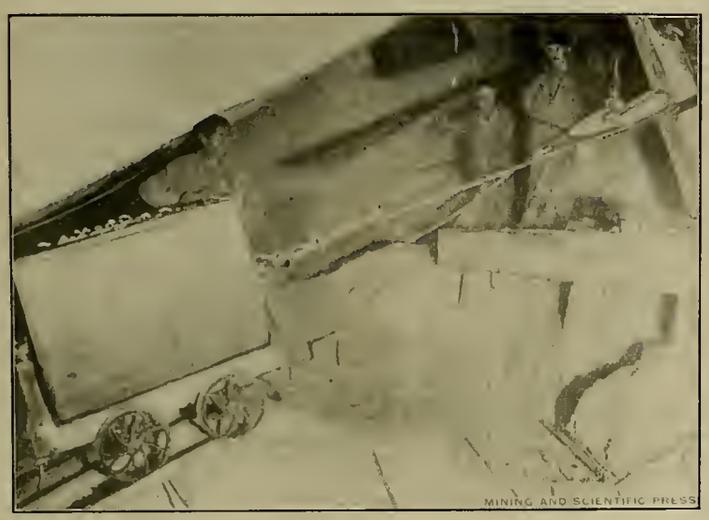


Fig. 1—Incline Plane Top, Nourse Deep.

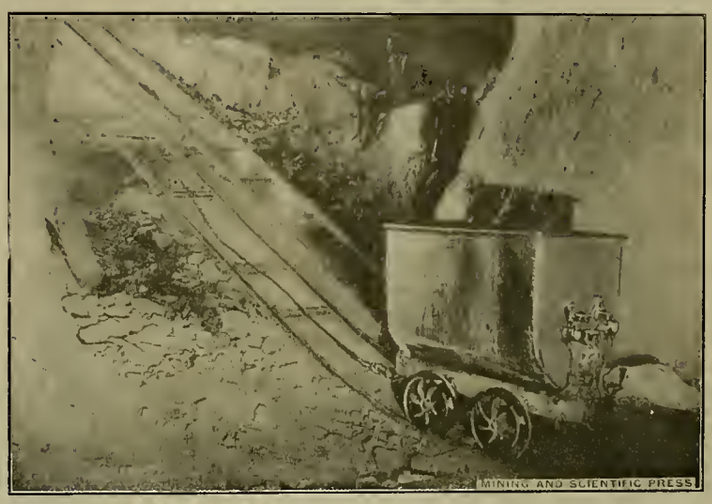

Fig. 2—Incline Plane Bottom, Nourse Deep.

There is another useful appliance recently introduced, known as a shaking chute (see Fig 3), which is most useful in flat stopes, and is being used so far in continuous length up to 90 feet, and even a 300-foot length is in contemplation. The shaking in this latter case will probably be done by mechanical means.

It consists of about ⅛-inch steel or iron plates, which are cut, bent, punched and riveted into lengths of 16 feet, having a width of 24 inches and bent to form a trough some 6 inches deep.

These lengths are easily handled and are bolted together to make up any desired length. It is hung by chains at intervals of about 16 feet to eyebolts fixed into drill holes in the hanging wall of the stope.

The shanks of these eyebolts are tapered from 1 inch to ¾ inch, and have been found to have a sufficient hold by being driven well home without the use of wooden plugs. Thus their subsequent removal can be easily effected.

"Boys" raise the ore by means of shovels into this trough, and one "boy" at the top end moves it backward and forward, and so shakes the ore downward, the ore at its bottom end falling in a nearly continuous stream into a truck, box or platform, as may be most convenient. This main shaker can be fed by subsidiary shakers, conveying the ore from various points in the stope face.

Some of the great advantages of these shaking chutes are their low initial cost, viz., about £14 per 100 feet, inclusive of labor and material; simplicity and portability, a 90-foot length taking forty minutes to take to and hang in position from the level, and fifteen minutes to dismantle and stow away again in the level. Thus they can be fixed into position very quickly and can easily be dismantled when blasting operations are about to be carried out. There seems

Fig. 3—Shaking Chute, Rose Deep.

*Trans. Chem., Met. and Min. Soc., S. A.

every possibility of this appliance being utilized to a much greater extent in the near future thau the majority of other appliances at pres-ent in vogne.

The following comparative test was made at the Nourse Deep, Ltd., to demonstrate the efficiency between "boys" filling trucks from the floor of the level as against filliug by shaking chnte direct into a truck.

The chute was 90 feet long, five "boys" being employed shoveling into the top length. The rate of time filling a truck was two minutes. conveying the ore over this distance of 90 feet. Two good Cape "boys" were pitted against this mode of filling, by shoveling broken ore from the floor of the level iuto a similar truck, which they filled iu four minutes, in this case only having to lift the ore into the truck. After the introduction of such a chnte in one of the stopes of the Nourse Deep, Ltd., the efficiency of the natives' shoveling was increased by 30%.

A somewhat similar contrivance is met with in belt conveyors of various designs. These generally consist of an endless rubber belt workiug round a drum at either end, supported under one side by a series of pairs of V-shaped rollers, the motive power being usually obtained by natives turning either one or both drums by a handle attached thereto.

In a case seen by the authors where such a belt was working in a very flat stope, and under the best conditions, this contrivauce did not seem suitable for the conveyance of large rock, as this easily fell off, and it lacked portability, which is au essential feature.

(TO BE CONTINUED.)

Gaseous Fuels for Power and Heating.

NUMBER III.—CONCLUDED.

Written for the MINING AND SCIENTIFIC PRESS by H. SHERWOOD, C. E.

The refuse of petroleum distilling, whenever able to be delivered at-low price, forms a cheap source of water gas at a price a little lower than from crude petroleum. In Europe no difficulty has arisen from its use. It requires the hard carbon of the gas generator to be of coal or of wood.

The heavy oils from bitumiuous shale are the richest in caloric of any known fuel—the gas from such being required not over 10 cubic feet per horse power per hour. They will surely be found in this country not distant from the Pacific ocean, and will form an economical source of power by first distilling them.

Wood is one of the most importaut fuels on the Pacific slope. In localities where no other fuel can be economical, wood may be used with great success in forming water gas. In most parts of Europe it is the most costly of fuels. Here the immense annual waste of wood is appalling—aud it is chiefly willful, merely to save present labor. But the wooded regions are usually many miles from the need for it. The cost of freight by mountain roads makes it a comparatively costly fuel where needed. Where wood has been used for making water gas in Europe special apparatus has been constructed, designed for it and peat. The data given are that from resinous pine wood there is given off 20% of watery vapor, with 12,500 cubic feet of rich gas per ton of air-dried wood, of which the calorific power was higher than rom most coal gas. The char is not over 400 pounds from the ton of wood employed, and this is about consumed by passing the distilled vapors and gases through it wheu incandescent. There is thus obtained 36,500 cubic feet of water gas, containing 44H $5CH_2$ 33CO $10CO_2$ 6N. No data given of the consumption in gas engine cylinder. From its consumption, about 40 feet per indicated horse power per hour may be assumed for engines of 80 H. P. Taking air-dried pine wood at $4.50, weighing 1¾ tons, this consumption of gas would assure power at 6¾ cents per iudicated horse power per twenty-four hours.

Considering that the wooded regions of the Pacific slope are rarely more than 20 to 30 miles distant from ore working requiring heavy motive powers, and that in many of these regions extensive water power is not found, it is quite a matter of sober judgment to utilize the extensive waste aud uatural perishing of pine wood in forested regions by producing there large motive power to be transmitted to places where such power is needed. The installation is not one-tenth of the capital sunk in developing water powers in regions where water powers exist; the production of power would cost no more than the interest on capital in the case of water power; the reproduction of pine is usually most luxuriant and rapid, and the supply need never fail. Much of the most valuable land of the Pacific coast region would thus be recovered for agriculture, of a class with difficulty accomplished elsewhere, while the wooded mountains assure the permanence of the industry. In the half-wooded regions where power is needed, immense quantities of wood are able to be delivered where consumed at two-thirds the cost rate given above, while the better class of wood is employed in mines as timbers and stoping poles. The common pine of this warmer, drier region of California is the Sabin pine (commonly known as the nut pine), which reprodnces and flourishes ou hot gronnds on which uo other pine can grow, and this pine is emiuently useful for producing power by water gas at probably lower cost than any other fuel can ever be furnished where needed.

Lignite is in some parts of the Pacific slope available as fuel for power by water gas, when it is not liked for steam producing. It can, therefore, be obtained at very low relative price. It is found in many places in California, Nevada, Oregon and Washiugton and lies neglected. For iustance, there exists in Washington, near the international boundary, large deposits, 20 feet thick, burning with a loug smoky flame and obtainable in large quautity by systematic mining at not over $2 per ton. Such a fuel is a most valuable source of power aud also of smelting fuel, by converting it into water gas, and at probably a lower price thau any given above. It is also found across the bonndary and not distaut from large consnmptions of fuel for power. The lignites are most extensively employed in Germany, and contain about three-fourths the calorific quality of good bituminous coal. They contain often much moisture which needs drying out, and occasionally too much ash to allow of their employment for ordinary fuel. In instances of water gas generators iu Europe, automatic means have been devised for removing the ash from such fuels, which means are satisfactorily used. At the price at which these lignites can be had in large quantities (and also wood, previously referred to), it may be remarked that they can be used to produce power by water gas and gas engine at from $12 to $15 a year for continuous power, at which price few electric power companies could produce a 6% dividend on capital.

It must be noticed that the whole of costs given above for power are the costs for fuel alone. The attendance needed for water gas and gas engines are about the same as for steam boiler and steam engine, only that in large powers, as but half the weight of fuel has to be handled as iu the case of steam, the stokerage is correspondingly less costly. Also it may be said that the cost of water gas generators is considerably less than the cost of steam boilers, and especially where heavy pieces of machinery (as boilers) have to be carried over inland roads. The cost of gas engines unfortunately cannot be reduced to lower than similar powers of steam engines.

Some notice must be given to the value of water gas as fuel and as an agent in smeltiug ores, roasting ores, heating uses in metallurgy, burning of lime and cement in kilns, glass making, potteries, etc. The value of gaseous fuel in iron smelting has long been recognized and discussed. It cannot be mentioned here. In smelting of copper and lead ores, it may merely be remarked that an agent so rich in heating power, so able to be applied just where and when it is needed, and having such a power in reducing oxides, as a gas coutaining more than 60% of hydrogen undoubtedly has, cannot be wisely neglected—although its use may be new to the operator's ideas, who on the Pacific slope generally take refuge in doing nothing which some one else is not previously doing in his sight. By the use of such water gas, combined with the hot air blast, a higher heat is attainable than by any other fuel, which is equivalent to less of this fuel than of any other. While it can be made oxidizing, it is a more powerful reducing agent than any other can be, and with much less cost than by coke. This is perfectly understood in the natural gas belts. By calculation of the combiuing power of hydrogen and of carbon this is easily seen. For roasting ores the employment of a fuel so regular in heat and so applicable to carry its heat commends it to general use. Glass works aud potteries cannot afford to be without its use. Its freedom from smoke and ash alone insures its use in every up-to-date establishment. In metallurgy its use is rapidly extending. Combined with the regenerative heating stoves, which can give the air or the gas at 1000° C., every metal can be rapidly liquefied. By the use of gas furnaces of the Griffiu type, the highest heat can be attained by the use of pure water gas, which any crucible can be made to bear. Platinum is easily melted by it. On an ordinary firebrick exposed to its greatest heat, a pair of tongs used to grasp it can be nipped together until they meet, and draw out the brick in rough long filaments. With such a heating agent and the most improved methods iu producing it from so many varieties of fuels—at prices which enable its use with so much economy over existing employment of the same fuel—this "progress stricken age" is doomed to allow the glare of knowledge to shine even into these distant regions and compel us to adopt ways now despised, because it cannot yet be said that "everyone does so."

Information to verify the economy of these generators will be given to employers of fuel, power, etc., by applyiug to the writer.

WHERE speaking of the diameter of pipes the outside dimensions are measured in well casiug and the inside diameter of steam and water pipes. Casing is usually made of much thiuner material than steam or water pipe of the same dimensions.

The Manufacture of Gun Cotton and Nitroglycerine.*

NUMBER II.—CONCLUDED.

Written by BRYANT S. DRAKE.

The glycerine is stored in drums which stand in the open air. Wheu glycerine is wanted, these drums are rolled into a small shed and emptied into a tank through a wire netting, which keeps out foreign substances. From this tank the glycerine is blown up by compressed air to a tank far from the storing place of the mixed acids. From here the glycerine and mixed acids are run directly into separate tanks holding one charge each and mounted directly on scales, so that each charge is accurately weighed just previous to the nitration. The scale tanks for the mixed acids are in two little buildings about 50 feet from the mixing house and outside the bulkheads which surround this dangerous place. They connect with the mixers or nitrating machines by means of ordinary draiu tiling firmly joined together and closed at each end by an earthen stopcock. They are made of riveted iron plates and hold over a ton and a half of mixed acids when full. The scale tanks for the glycerine, on the other hand, are mounted on smaller scales beside the mixers and are made of wood. The flow of glycerine to the mixer is regulated by an ordinary stopcock.

The mixer itself, although a complicated looking affair, is in reality very simple, both in theory and construction. It consists of a large riveted iron tank, 7 or 8 feet in diameter and about 4 feet high, containing a large leaden coil through which cold water flows aud a set of three bronze propellers to keep the liquid in coutinual agitation. There is also, near the bottom of the tank, running in towards its center, a set of small pipes through which compressed air may be forced to keep the liquid agitated in case the power agitating the propellers fails. The power is not calculated to fail, however, since the shafting which actuates all the propellers is attached to one end of an electric motor and at the other end a steam engine. A long lever extending alongside the mixers enables the attendant to couple the engine on in a moment, in case the electricity should fail. The leaden coil that carries the cooling water is in three separate sections, each with an independent valve. Each tank is connected to a fine by means of an outlet of which one sectiou is made of glass in order to enable the attendaut to observe the character of the fumes evolved. Each tank has also a three-way outlet cock so that the nitroglycerine may be sent either to the separators or to the drowning tanks directly underneath. These latter tanks are 12 to 15 feet high and 8 to 10 feet in diameter. They are kept constautly full of water and are provided with air valves to agitate the water. They are used only in case a charge of partly nitrated glycerine and acids takes fire. When this happens, the mixture is at once run into the drowning tanks to extinguish the fire and prevent explosion. By no means the least important of the accessories of the mixer is the thermometer. This registers the temperature of the mixture during nitration. The reaction of the HNO_3 on the glyceriue produces water which is taken up by the sulphuric acid with the evolution of heat. If the temperature rises above 30° C., the flow of glycerine is shut off and the temperature of the mixture is rapidly reduced by water flowing in the leaden coils. The cooling water flows through these coils by gravity, and is then returned by an electrically driven centrifugal pump to the tank whence it came. Melting ice is always kept in this tank during the process of nitration.

At Pinole there are four mixers and four complete sets of separating and washing apparatus. The units of each set are placed side by side to secure economy of supervision, aud in the mixing house two men tend the four machines. As the yield of nitroglycerine is about 2.4 times the amount of glycerine used, each 900-pound charge yields over a tou of nitroglycerine. The four charges are run simultaneously. The nitration of 900 pounds of glycerine requires about fifty minutes.

From the mixers to the separators the charge is conveyed in opeu leaden troughs 600 feet long, the object of this distance beiug that if either the separating house or the mixing house is blown up, the other need not necessarily go too. This, however, is a chance only, as either house generally contains at least four tons of nitroglycerine, and at certain periods of the day there are from nine to twelve tons distributed between the two buildings. Then, too, the blowing up of one building would be apt to disarrange the machinery in the other sufficiently to cause a second explosion, even if the concussion itself did not.

The charge as it leaves the mixers is a thick, whitish liquid, which gives off white fumes in considerable quantity, so that, while it is running in the troughs, the fumes rise and cut off vision in about 20 feet.

(TO BE CONTINUED.)

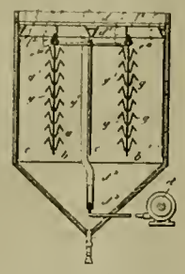
*Abstract California Journal of Technology.

Mining and Metallurgical Patents.

PATENTS ISSUED JANUARY 19, 1904.

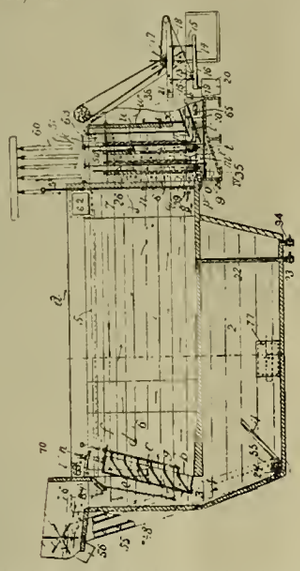
Specially Reported and Illustrated for the MINING AND SCIENTIFIC PRESS.

APPARATUS FOR EXTRACTING PRECIOUS METALS BY ELECTROLYSIS.—No. 749,844; H. R. Cassel, New York, N. Y.



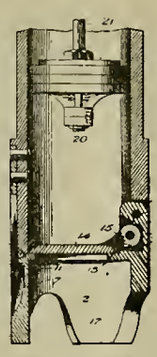
An apparatus for extraction of precious metals by electrolysis provided with tank, vertical electrodes, distributing pulp box, mercury pot in upper part of tank, perforated movable mercury trough, and means for lifting pulp and mercury into distributing box and pot, respectively.

GOLD-SAVING APPARATUS.—No. 750,227; L. Sachse, Los Angeles, Cal.



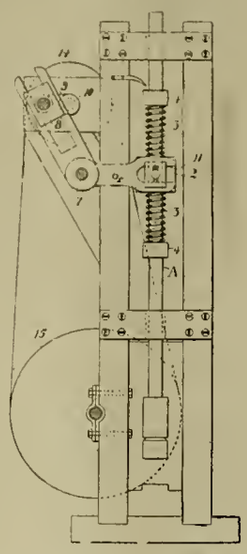
In gold-saving apparatus, combination with tank having upper and lower compartments arranged one above level of other and having floor between them, and communicating with each other through opening in floor, of means for supplying gold-carrying water to tank vertically above opening; means for restricting outflow from upper compartment; and means vertically over opening, adapted and arranged to intercept inflowing liquid and to direct precipitants from such liquid through opening into lower compartment.

SAND PUMP.—No. 750,192; F. G. Irvine, Marietta, Ohio.



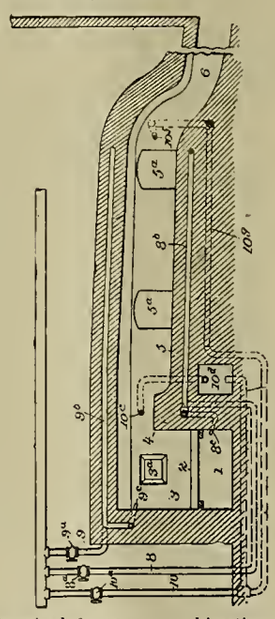
Sand pump or bailer for wells, comprising tubular portion having flat face formed on lower end at right angles to axis, bottom section of same exterior diameter as tubular portion provided with upwardly opening valve and having flat face at upper end to fit against flat face formed on tubular portion, hinge connecting bottom section to tubular portion, longitudinal recess formed in exterior of tubular portion opposite hinge, catch arranged in recess and secured at upper end to tubular portion, longitudinal recess formed in bottom section to receive catch having shoulder formed therein, and cross-recess formed in bottom section below shoulder.

STAMP MILL.—No. 750,006; G. C. Richards, Berkeley, Cal.



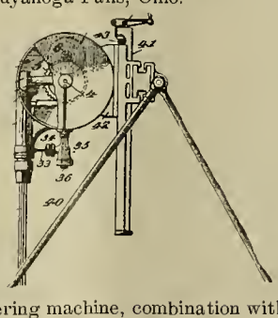
The combination with vertically guided and movable stamp stem, having tappet slidable upon it, lifting stop above and compressible spring below and in contact with tappet, of rigid bell crank lever having its angle fulcrumed at one side of line of travel of stem, connections between one arm of lever and tappet, and slidable connections between other arm and operating crank.

METALLURGICAL FURNACE.—No. 750,022; W. S. Dempsey, New York, N. Y.



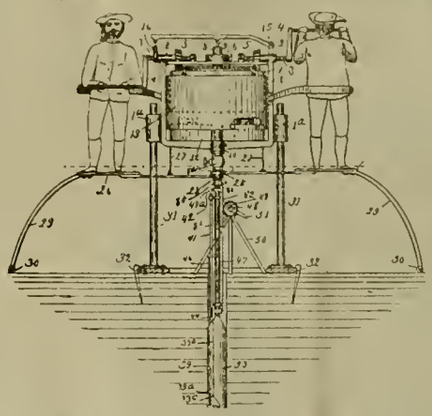
In metallurgical furnace, combination of working chamber and combustion chamber opening into same, oppositely disposed blast pipes below and above grate in combustion chamber, blast above grate being arranged to drive gases generated toward working chamber and blasts below grate being directed angularly in opposite direction to those above grate, and cross blasts within working chamber directed from opposite sides of chamber and backward toward combustion chamber.

POWER HAMMER AND ROCK DRILL.—No. 749,996; J. Kraus, Cuyahoga Falls, Ohio.



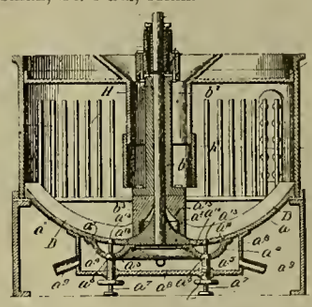
In hammering machine, combination with frame or casing, motor driven pinion mounted in machine, gear with which pinion meshes, one or more hammers provided with arms pivotally connected directly to gear, and anvil or like in line with hammers when in outermost positions.

PROSPECTING INSTRUMENT.—No. 749,718; M. Chase, Haverhill, Mass.



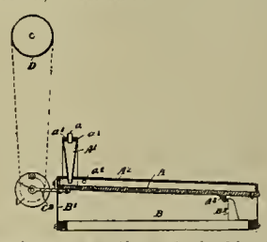
Prospecting instrument comprising boring tool having pair of liquid tight passages connected at lower end of tool, and extending longitudinally thereof, means for operating tool, reservoir and means for circulating heated liquid through reservoir and passages.

AMALGAMATOR AND CONCENTRATOR.—No. 750,224; J. B. Rossman, St. Paul, Minn.



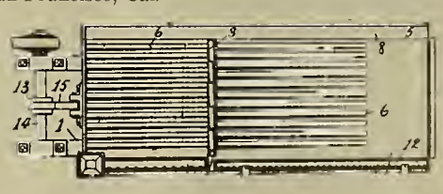
Apparatus of character specified, comprising a bowl having curved bottom slightly rising in center, in combination with rubbers centrally pivoted, extending radially and having close contact with bottom; means for imparting circular, oscillatory motion to rubbers, and rods projecting above rubbers and operating to disintegrate material within bowl and to break up any currents formed therein.

PROCESS OF SEPARATING ZINCBLENDE FROM ORES.—No. 750,034; W. Jamiesou and F. J. Odling, Melbourne, Victoria, Australia.



In process for separation of zincblende from ore with which it is associated, treating ore when in sufficiently wet and pulverized condition with chlorine, in order to attack surface of zincblende, and submitting ore so treated to vanning motion sufficient to bring zincblende particles together and allow them to adhere to each other, forming small masses.

CONCENTRATOR.—No. 750,075; W. G. Anderson, San Francisco, Cal.



Concentrating table sloping to one side and provided with means for imparting thereto longitudinal reciprocating movement and consisting of upper and lower portions located longitudinally or endwise of each other, each portion sloping longitudinally downward from feed end of table, portions having transverse drop therebetween, each portion having longitudinal riffles, riffles of upper portion extending down to drop, trough at drop for conveying pulp to upper side of table, said trough having holes for distributing the pulp upon the lower portion of table, and means for removably and selectively closing holes, and series of spouts inclined downward toward upper side of table, and discharging from upper riffles into trough, in combination with means for discharging pulp upon the upper portion and water upon the lower portion.

Mining Summary.

SPECIALLY COMPILED AND REPORTED FOR THE MINING AND SCIENTIFIC PRESS.

The following table gives the twenty-five principal copper producers of the United States, with their approximate 1903 output in pounds of refined copper, according to H. J. Stevens of Houghton, Mich., with production for 1901 for comparison:

	Estimated. 1903.	Actual. 1901.
Anaconda (Mont.)	95,000,000	101,850,224
Calumet & Hecla (Mich.)	80,000,000	77,761,382
Boston & Montana (Mont.)	25,000,000	50,000,000
Copper Queen (Ariz.)	37,500,000	39,781,233
United C. Co. (Mont.)	32,000,000	29,898,980
Arizona C. Co. (Ariz.)	30,000,000	20,535,800
United Verde (Ariz.)	30,000,000	34,520,693
Mountain C. Co. (Cal.)	25,000,000	29,737,040
Calumet & Arizona (Ariz.)	25,000,000	.....
Detroit C. Co. (Ariz.)	20,000,000	17,535,000
Quincy (Mich.)	18,750,000	20,540,720
Butte Red'tion W'ks (Mont.)	18,000,000	17,969,663
Tamarack (Mich.)	15,750,000	18,000,852
Utah Con. (Utah)	12,500,000	6,000,000
Tennessee C. Co. (Tenn.)	12,000,000	6,000,000
Bingham (Utah)	12,000,000	1,041,801
Parrott (Mont.)	12,000,000	10,167,850
Champion (Mich.)	11,000,000	.....
Shannon C. Co. (Ariz.)	11,000,000	.....
Baltic (Mich.)	10,500,000	2,641,432
Trimountain (Mich.)	10,000,000	.....
Wolverine (Mich.)	9,100,000	4,946,126
Old Dominion (Ariz.)	9,000,000	10 094,787
Butte & Boston (Mont.)	9,000,000	8,028,746
Colorado M. & S. Co. (Mont.)	9,000,000	7,465,260

A feature of the preceding is that Montana, Michigan and Arizona, the three leading copper fields of the United States, have seven mines each in the list, while Utah, a comparatively new producer, has two, and California and Tennessee one each.

ALASKA.

H. H. Williams of Juneau has bonded the Glacier Basin mines for New York parties and will operate them. He is principal owner of the Gold King and the Humboldt mines, both quartz properties. The latter has a 10-stamp mill in operation and will add five stamps. The Gold King is in Berner's Bay district.

ARIZONA.

Cochise County.

A gold strike is reported made in the Santa Rosa district, 14 miles from Douglas, showing a ledge 6 feet wide having 15 inches of pay streak. It carries wire gold.

The underground workings in the Commonwealth mine, at Pearce, have caved in to such an extent that the owners have shut down the mill and ceased extraction of ore for the present. Work has started in sinking a new shaft from which all lower workings can be reached with safety and cleaned out and retimbered.

At the Nugget mine the No. 1 tunnel running on the ledge, 400 feet below the apex of the vein, is reported to have cut last week a shoot at 100 feet that assays $100. Tunnel No. 2, at 150 feet deeper on the ledge, has cut this same shoot at 140 feet. Pritchard & Jones, operators, are preparing to put up a stamp mill.

Maricopa County.

(Special Correspondence).—J. G. Hardin and R. H. Roberts report locating a number of promising claims in Tip Top district, near Phœnix.—The Arizona M. & D. Co., operating the Montezuma lead mine, near Morristown, has put on additional men.——A number of properties are being worked in the White Tank mountains, north of Buckeye.——G. Francis is working men on his mine west of Morristown.—R. E. Humphries expects to put men to work on his claims, east of Morristown, next week.——La Gloria M. Co. is taking out shipping ore, which is being hauled to Beardsley.

Phœnix, Jan. 25.

Suporintendent T. Crandall of the Confederate M. Co. mines, in the Sunflower district, west of Globe (Gila county), says work is progressing. At depth of 80 feet bodies of high-grade ore are showing in several openings. One vein shows 10 inches of copper glance on the Chicopee claim. Also, on the Monitor claim at 30 feet in depth ore is showing.

Mohave County.

The Sheeptrail mill, 40 miles above Needles, Cal., is again dropping its stamps. This mill has been idle for some time on account of legal difficulties.

F. O'Dea reports opening up a body of gold-silver ore on the south end of the Oro Plata mine, near Kingman, showing native and ruby silver. He has a carload of the ore on the dump ready for shipment. From the bottom of the 280-foot level the distance to the south shoot is 100 feet.

J. Carter has a lease on the Billy Bryan mine, at Gold Road, and is getting out gold ore from a streak 18 inches wide.

Pinal County.

(Special Correspondence).—Thirty men are at work at Superior. Ore has been opened up.

Superior, Jan. 25.

C. Udell is arranging to work the deposits of fire clays and other clays near the Atchley ranch, above Mammoth, on the San Pedro river, and on the line of the Phœnix & Eastern Railroad.

G. B. Chittenden reports having struck a 3-foot vein of coal in the shaft being sunk on one of the claims west of Saddle mountain, 8 miles from Dudleyville.

Santa Cruz County.

At the Tres Amigos gold mines at Oro Blanco the mill under Superintendent F. Lanyon is in full operation.

Yavapai County.

G. P. Harrington, of the Tiger G. M. Co., has three 100 H. P. boilers and one 100 H. P. air compressor on the ground at their group in the Bradshaw mountains, southeast of Prescott. One of the boilers will be put into the mill and the other two and the air compressors will be used in development of the mine. Ten more stamps and additional concentrating tables will be put in the mill.

G. W. Sarano, of the Ideal M. Co., at Groom creek, reports a strike made in the south drift at 135 feet, showing a body of ore 3 feet in width that runs $30 per ton in gold.

C. W. Platt says he is grading for the mill at the Illizona M. Co. mine near Kirkland. The shaft, which is down 200 feet, will be sunk to 500 feet before further lateral work is done. A hoisting plant, air compressor and machine drills are being put in. A 10-stamp mill will be built.

The United Verde smelter at Jerome is working two 500-ton and one 250-ton jacket furnaces, the Jerome News says, smelting 1250 tons of ore daily. They are hoisting but 800 tons per day from the mine, the remainder of the supply for the smelter coming from the roast. The company is building another 500-ton furnace, and rebuilding two more 250-ton smelters, all of which, when put in operation, will give the United Verde Co. a smelter capacity of 2250 tons a day. To supply this the number of miners will be increased.

Yuma County.

E. S. Osborne has taken over a number of claims near the Billy Mack group on the Colorado river, near Parker. He has men at work on copper and gold mines on Bill Williams Fork owned by himself and others.

CALIFORNIA.

Amador County.

Newman et al., who have bought the Pine mine on Mokelumne river, near Pioneer, are opening the mine by a tunnel which will strike the ledge 100 feet below the old workings. They are building a road into the mine from the West Point bridge.

Butte County.

J. C. Rowan, of Helena, Mont., and Eastern men have bought a quartz mine on Bloomer Hill, 16 miles from Oroville. A crosscut tunnel, 180 feet long, has been run. The company will put on men next week. They will build a stamp mill.

Around Oroville several drilling outfits are working night and day, prospecting new ground, and six more dredgers are being built in addition to the twenty-four in operation. The American Dredging Co. is constructing one of these dredgers on the Hilgers ranch, on the Gardella tract; Leggett No. 3 is ready for the machinery; the Central Dredging Co. has another boat under way on the De Lancie place; on the Wilcox land W. P. Hammon is building another; W. T. Bagget of San Francisco has material on the ground for building a dredger on his land, and El Oro D. Co. is preparing for another dredger on the Springer land. The latest dredger in operation is the El Oro, which cost $92,000.

Calaveras County.

The Independence gravel mine at Angels is renewing operations. The shaft is 200 feet deep, 90 feet below the gravel, at which point a drift 14 feet has been run.

Work will be resumed next week at the Jones mine, near Angels.——The Allison mines, adjoining the Jones mine, are said to have been bonded and work will start next month.

El Dorado County.

At the Santa Claus quartz mine, near Greenwood, hoisting machinery is being set up.——It is reported that the tailings and sulphurets from the Rattlesnake mine, near Garden Valley, which are being treated by the cyanide process at the Rosencrans plant, assay $20 in gold. It is said the ore when run through the mill did not yield enough to pay for mining it, but it is thought operations will be resumed on the mine and the ore treated by cyanide.

A 30-ton smelter is being built for the Rio Vista gold and copper mine near Nashville. It is expected to be ready to blow in by March 1st, says the Georgetown Gazette.——The steam hoist at the Ida Mitchell mine at Placerville was started up last week. D. H. Jackson is superintendent.

Kern County.

The Standard Oil Co.'s pipe line is expected to resume operations between Kern river and Mendota next month, says the Californian. The reopening of the line is due to the fact that the company has succeeded in relieving the situation at Coalinga, where large quantities had been in storage waiting a chance to be brought to market, and it was not possible to use the pipe line for both oils at once and get any relief. During stoppage of the line from Mendota south work at Kern river has been held up on several properties.

Mono County.

Superintendent Colcord expects to have stamps dropping at the Esmeralda Con. by February 1st, says the Bodie Miner-Index.——The New Bodie M. Co. has twelve men at work. The University shaft has been cleaned out to the 300-foot level and retimbering is under way.——At the Sunshine a crosscut is being run, being in 200 feet. A drift is being run on a 12-inch vein of ore at the Eva.

Nevada County.

Superintendent C. Graham of the Canfield mine near Nevada City says he has started a raise to reach the gravel from the drift. The drift is in 1200 feet. The air compressor has been set up.

Operations will be resumed at the Tule Belle mine, says D. E. Matteson, president. The company owns 131 acres of mineral land on Cincinnati Hill, on which a three-compartment shaft, 200 feet in depth, has been sunk. It shows a ledge, which has yielded ore. The shaft is equipped with a double-drum hoisting engine, pumps, etc. It is near Grass Valley.

At the Culbertson mine in Eureka district, Superintendent English reports uncovering a pay shoot in the 6-foot ledge on the hanging wall side. The Culbertson is 1½ mile from Graniteville and 3 miles from the Gaston Ridge mine. The Syracuse & California M. Co. of New York is developing the Culbertson and the National mines.

The Seven-Thirty mine on Deadman's flat, near Grass Valley, will be reopened, work starting next week, says Manager G. W. Root. It is intended to sink a new shaft and equip the mine with heavier machinery.

At the New York - Grass Valley mine, near Grass Valley, the stamp mill was put in operation last week. With a quadruple discharge and a coarse mesh screen the nine stamps are expected to make output of 125 tons, daily, says Superintendent White. Bodies of ore have been blocked out in several levels. The shaft will be continued down, and at each 100 feet new levels will be driven.

J. McCaffrey, superintendent of the Polar Star mine, near Grass Valley, says the mine will be reopened next month, according to instructions from J. A. Kirby of Salt Lake City, Utah, manager.

The unwatering of the Mountaineer mine, near Nevada City, having been completed, Superintendent Campbell has put on men to drive the 400-foot and 700-foot levels south. In the face of the 400-foot drift there is a 2½-foot vein of ore.

Work has resumed on the new shaft to be sunk on the Green Mountain mine, near Grass Valley, says Manager Labadie. A raise was started from the 800-foot level and work also begun from the surface. The shaft is 16x6 feet in the clear and is down 100 feet from the surface. The raise is up 110 feet. It will be equipped with a hoisting plant, after which they will go below the 800-foot level. Development work will be increased on the Centennial, under the same management, when it has been unwatered.

Placer County.

The owners of the Elite mine at Shady Run near Towle's are running a prospect tunnel of 400 feet, to strike the channel.

Plumas County.

The Cataract mine, near Quincy, has been sold to W. Whitaker, W. J. Schneider and W. Arndale, who will develop the mine. It is northeast of the Penman ranch and south of Grizzly ridge.

At Indian valley, near Genessee, R. E. Carswell and H. Anderson, of Minneapolis, Minn., holding the Peter quartz mine under bond, are arranging for the mine to be opened up and operated by the Regal M. & L. Co. of Minneapolis, of which Carswell is president. They are putting up a mill of ten stamps with concentrators. It is expected to be put in operation in March. A contract has been let to run a tunnel. The mine is above the level of the north arm of Indian valley. The machinery will be run by water power, the pressure obtainable being 160 feet, and will be applied to a 5-foot Pelton wheel. A cyanide plant is also proposed.

Sacramento County.

The Folsom Dev. Co. dredger No. 1, on the Billingsley place, near Folsom, is completed and is expected to be in full operation next week. It will work to a depth of 40 feet below the water level. Dredger No. 2, on the Reed place, will be completed in two weeks. It is smaller than No. 1, working only to depth of 25 feet. S. A. Martindale is superintendent of the two dredgers. The company's machine shop is running with twelve men at work.

Santa Barbara County.

Development of the oil industry around Lompoc is reported improving. While the oil sand is deep, there are three producing wells in this section and more are going down. One well is 3140 feet deep, with 730 feet of oil sand. This is said to be the deepest producing oil well in the State. It is in the Los Alamos valley, in the northern part of the county. The oil sand is thought to go deeper, but it will be impossible to get much greater depth with the casing, as there is heavy pressure of gas at the bottom of the well. The well is kept full of water to keep down this gas, and it is thought that when the well is turned on it will give 1000 barrels per day. When tankage is ready to receive the output, the well will be turned on. As soon as the gas pressure is relieved, the pump will be worked regularly. The well is owned by the Union Oil Co. (being Hill No. 2). Near by is a well, penetrating the oil stratum to depth of 150 feet, which pumps 250 barrels of oil per day. The Union Co. owns this well also, and is putting up a derrick for a well to be drilled 1½ mile west of its Purisima wells. A pipe line to the ocean has been completed.

Shasta County.

The dredger of the California and Detroit Dredging Co., operating near Horsetown, 9 miles southwest of Redding, has started up, replacing the one destroyed by fire last summer. The dredger is operated by electrical power. The company proposes building additional dredgers, as it has more placer ground than one can handle.

Crude oil will replace wood as a fuel at the smelter of the Bully Hill C. M. Co. at DeLamar, though the smelter is in a timbered country, and oil will have to be hauled by teams 18 miles from the railroad terminus at Bella Vista. The main source of power at the smelter is electricity, which is furnished by the Northern California P. Co. which also supplies the smelter at Keswick and the Afterthought mine at Bella Vista. But at DeLamar steam has always been kept up under one set of boilers so that steam power would be quickly available in event of power line being disabled by accident. Wood was used for fuel under the boilers. The only use the company will now have for wood will be to bed down the roast heaps of sulphide ores. This requires 3000 cords a year.

Siskiyou County.

The Fernandez hydraulic mine near Yreka, in Cherry Creek district, has resumed. It can be worked only a few months each season on account of the scarcity of water with which to operate the giants. There is a great deal of snow on the mountains at present, and prospects look favorable for this season says the Bee. The boiler at the coal mine, 6 miles from Yreka, burst last week and operations are temporarily suspended.

Tuolumne County.

J. Michel of Sonora has bought the Sievert quartz claim and the northeast extension of the Sievert mine, 2 miles northeast of Sonora.——O. M. Rising of East Oakland has taken over a half interest in the Rising Sun, New Discovery and Sonorita quartz claims, near Arastraville.

The Yankee Hill M. Co., operating the Vine Spring mine, near Columbia, will increase the mill from two to seven stamps and add a cyanide plant to handle the output of the mill.—R. Grun of Carters has bought the Manzanita quartz mine, on the Buchanan ridge (formerly the Blue Bird mine), near Carters.—E. G. Kennedy has bought the Big Fern mine, 3 miles north of Jacksonville.

S. W. Wilhelm is putting up a 4-stamp mill on the Vivian and Concord claims, a mile above Parrotts Ferry bridge, on the Stanislaus river, near Columbia. He made final payment on the Concord last week. Three more buildings have been completed.

COLORADO.

Archuleta County.

The Wilkesbarre-Colorado Oil Co., which has a lease on the school section near Pagosa Springs, has two outfits of tools on the ground and will begin drilling for oil this week.

Chaffee County.

The Waverly-Badger G. M. Co. at Turret is putting in plant of machinery on the Badger mine, consisting of a 50 H. P. boiler, 6x8 steam hoist, duplex pump, cages, trams, et al. The Waverly-Badger group consists of seven claims 1 mile north of Turret mountain and 2 miles northwest of Manoa on Cameron mountain. The country rock is said to be trachyte,

but they are developing a 2-foot vein of hematite, which, at depth of 75 feet, carries values in gold. The Badger group is owned by Iowa men, with C. T. Brown of Waverly, Ia., president. S. Stoner of Turret is local manager.

Clear Creek County.

At the Mendota mine, near Silver Plume, the management is preparing to put in larger boilers and hoisting machinery to increase development work.

At the Stevens mine, near Silver Plume, the 50-ton concentrating mill was put in operation last week.

The Terrible mill at Silver Plume resumed operations last week, after idleness of several weeks. The mill was closed down on account of the water pipes having frozen for distance of 5000 feet. An attempt was made to thaw the line by blowing steam from the power house, but this was found to be impossible as the distance was too great. An engine and boiler were then placed at the other end, with better success. It is stated that fifty men worked for several days keeping fires going along the course of the pipe line.

At the Hood & Maxwell Grillith mine, near Georgetown, last week 12 inches of smelting ore were opened up, giving 300 ounces in silver and 0.6 ounce in gold. In addition to the gold and silver the ore carries copper and lead. The strike was made in a winze sunk from the 300-foot station of the tunnel level at depth 30 feet and in a drift from bottom of winze. That portion of the Grillith vein operated by Hood & Maxwell is producing ore from ground operated by lessees and regular shipments are being made.

Custer County.

The shaft of the P. & O. mine, near the Bassick mine, near Silver Cliff, is down 600 feet, and crosscutting and drifting on the streaks of high-grade gold ore are under way. Ore is a telluride. A plant of machinery is on the ground.——It is reported work will be resumed on the Hector group, near Custer City. There is a shaft sunk to a depth of 200 feet.

Fremont County.

Mica mining is under way northwest of Florence at Micanite by the United States Mica Co., composed of Chicago, Ill., men. Plans are being drawn for a mill which will be built this spring, says Manager R. W. Menk. Several carloads of mica have been shipped.

The Portland Cement Works, near Florence, which have been closed down since the Colorado coal strike, will reopen next week.

The United Oil Co., while drilling well No. 312 at Spindle Top Heights, 3 miles south of Florence, struck oil last week at a depth of 2775 feet. Manager Wallace says the oil in the new well rose to near the surface and 500 barrels per day can be pumped.

The Metallic cyanide mill, 2 miles north of Florence, the property of the United States R. & R. Co., was burned last week, causing a loss estimated at $100,000. The origin of the fire is not known. This mill which has not been operated since becoming the property of the U. S. R. & R. Co., was being dismantled and the machinery being shipped to Utah. A large quantity of the machinery was stored near the mill in sheds and some of it was damaged, rendering it worthless. The mill was closed three years ago on account of the men asking for shorter hours and an increase of wages, which was refused. At that time 300 men were kept at work.

Gunnison County.

G. S. Givens, manager of the Monarch M., M. & D. Co., is developing the Kimberly, recently leased, near Sherrod, near Pitkin.

Las Animas County.

A new coal mine near Suffield is being opened up, 1½ mile northwest of Bowen station. It is on the same vein as the Union Coal Co.'s mine, says the Times. A tramway is being built and shipments of coal will be started. The Colorado & Southern Railway has put in a sidetrack for loading and all the material is at the tipple site. Fifty miners will be employed.

Ouray County.

The Ouray Con. M. Co., in which St. Louis, Me., men are interested, has taken over eighteen claims in the Blowout district, near Ouray. They propose to tunnel from Blowout gulch and into the Cascade range.

San Juan County.

The Iron Hat C. G. M. Co., with properties in Prospect basin, near Silverton, including their Crown Prince mine, will start development work this week. A contract will be let on the Crown Prince tunnel. Native copper has been found on the claim, says Manager Horrington.

San Miguel County.

The ore chutes in the Smuggler-Union mine, near Telluride, are being filled and next week Manager Wells expects to put more stamps in operation. There are 200 men employed by the company (but one-half the full working force). The tramway is running steadily, and it is expected the ore hins at the mill will be filled by Feb. 1.

Teller County.

W. W. Rasor, operating on the Valley View claim of the Spar G. M. Co., on Guyot hill, reports having struck payable ore. He has driven the tunnel 110 feet, which is 90 feet from the surface. The lead is 3 feet wide and is thought to be the El Paso shoot. He will follow it and increase development.

The Fremont M. & D. Co. of Florence, A. F. Myers, president and manager, is preparing to build a power plant and a reservoir on High park, near Victor.

The Bayard M. & L. Co., operating the Trilby claim, adjoining the Gold Sovereign mine on Bull hill, Cripple Creek, will put in a heavier plant of machinery which will have a capacity of 1000 feet. The shaft is down to 500 feet. Ore is being taken from two drifts, one at depth of 300 and the other 500 feet. This ore is giving smelter grade returns and the shoots in both drifts are 3 feet in width. The company is shipping out three cars of ore per week. The largest shoot was struck in sinking the shaft. This shoot has now been followed for some distance. Sylvanite and free gold are found in the ore.

The Peggy G. M. Co., owning the Le Clair claim, near Anaconda, is shipping out at rate of two cars per week. The ore is giving returns of six ounces gold per ton. Most of the ore is coming from a stope 15 feet south of the shaft at depth of 320 feet. In the north drift there is ore, but so far Manager Gilpin is not pushing development in that portion of the property. The screenings from the ore return six ounces gold per ton, while the coarse rock runs two ounces.

On the 26th inst., fifteen men were killed and one man severely injured as the result of an accident to the hoisting engine at the Independence mine at Victor. In the main shaft of the mine sixteen men were being hoisted in the cage from the sixth, seventh and eighth levels. When the cage reached the surface the brakes failed to stop the engine, and the cage with its load was drawn up in the gallows-frame, the strain on the cable causing it to part and releasing the cage, which dropped 1500 feet down the shaft into 20 feet of water in the sump. Similar accidents, in which no lives were lost, are said to have occurred twice before at the Independence from the same cause.

IDAHO.

Blaine County.

The Newton Revis placers, comprising 120 acres on Little Smoky river, near Hailey, have been sold to Hollister et al. of Hartford, Conn.

Boise County.

A. and E. Small and F. Long are working placer ground at Warm Springs, near Idaho City. The gravel is 8 feet deep.

Canyon County.

The coal fields on Indian creek will be developed by the Diamond Coal Co., which has been incorporated by O. H. Calander, F. A. DeClark, A. Thommen of Emmett and M. Hawley and W. W. Paxton of Boise. They have coal rights for several sections of land on Indian creek and have opened a 2-foot and 3-foot vein of lignite coal. Five men and a drill have been working for two weeks. The coal fields are 22 miles north of Emmett.

Elmore County.

(Special Correspondence). — The old camp at Atlanta is taking on new life and there is much activity in mining here. The Monarch and Benton groups of mines are being developed with good results, and in the Minerva it is reported that on the 200-foot level a vein 4 to 5 feet wide carries values of about $200 per ton, with a richer streak of 6 to 7 inches of high-grade ore. This is a gold camp and is attracting attention from outside. It is expected the comiug season will see large development in this camp.

Atlanta, Jan. 25.

Idaho County.

The Lewiston Tribune reports 150 miners on the payroll of properties operating in the Buffalo Hump district.

Eastern men proposo to build an electric plant at Buffalo Hump, to supply power for the mines and mills, says H. M. Lancaster of Rathdrum, consulting engineer for the company. Lancaster says, owing to the high prices of fuel at the Hump, there is opportunity for favorable investment of capital in a power plant. Surveys have been made. They had hoped that water power up to 1000 H. P. could be secured, but only 400 H. P. was found available that could be counted upon all the year through. The Crackerjack mine has developed 300 H. P. for its plant.

Lemhi County.

A ledge carrying tin values is reported found 3 miles west of Salmon City. O. E. Kirkpatrick of Leesburg says the ore assays 10% tin, 20% lead and $4 in gold. Stream tin has been obtained in this section for several years, especially in Panther creek, near Forney. There is a shaft down 30 feet on the ledge.——Kirkpatrick, who is superintendent of the Gold Flint mine, in which Salt Lake City, Utah, parties are interested, says 1900 feet of work has been done on this group of ten claims, opening up a 20-foot ledge of ore which averages $5 in gold per ton. ——The Gold Dust group, next to the Gold Fliut, is owned by Salt Lake City parties. A 10-stamp mill is in course of construction, and it is expected the plant will be in operation in the spring.

Shoshone County.

The shaft on the Hypotheek mine, near Wardner, is down 50 feet below the tunnel level and at 60 feet they will start to crosscut. The bottom of the shaft shows concentrating ore, which was found all the way down, says the Wardner News. The vein is 60 feet in width. The shaft is a 6x9 compartment. O. Guay is principal owner and manager.

P. Burke is reported to have an option on the Champion group, on Stephens peak, near Mullan. The property has been under development for four years and 400 feet of tunnel have been run. Burke is chief owner of the Park group. The Park and Champion are said to be on the same lead, on opposite sides of the hill. The tunnel in the Park has been run in 2000 feet. They are said to show values in copper. The mines are about 4½ miles from Mullan.

KANSAS.

Cherokee County.

At Baxter Springs the mill for the Sunny Side mine is being set up.——A. W. Abrams has made a strike of jack on his farm.——The north shaft of the Tom Clark mine has gone through 16 feet of lead.

At Galena, Wilkes & Co., on the Henry C. mine, have finished sinking to the 160-foot level.——J. E. Thrasher says a 500-foot drill hole will be sunk in the spring on ground south of Galena, where indications of oil have been found.

J. C. Moore, with Kansas City parties, is sinking a shaft on the Murphy ground, near Empire. Last week in sinking they struck a 10-inch "vein" of coal at depth of 22 feet. A drift will be made to open up the coal. The shaft is being sunk for ore, which the drill holes show at 75 feet.

MICHIGAN.

Houghton County.

The second shaft of the Calumet & Hecla mine on the Kearsarge lode, near Calumet, has been "bottomed" on the ledge, says the News. No. 1, which struck the ledge Dec. 1, is in the rock 40 feet. It is thought the lode lies to the east, in which case vertical shafts will be cut. Diamond drill work has been progressing since October.

The Franklin mine at Hancock is expected to show increased production during January. The mine is said to be improving in the lower levels of the Franklin Jr.

Houghton reports say negotiations are under way for the sale of the Arcadian mill to the Centennial C. M. Co., near Calumet.

The Elm River copper mine at Winona has entered the lode again at the 500-foot level and is crosscutting.——The two diamond drills of the St. Mary's Mineral Land Co. are working near the Winona, one within 1000 feet of No. 3 shaft of the Winona, where the showing is said to be encouraging to both the Winona and St. Mary's.

The trammers at the Quincy mine, at Hancock, went out on a strike last week, resulting in closing down the mine and also the mill, due to lack of stamp rock, rendering 1800 men idle. Blacksmith, machine and carpenter shops were also closed, under threats of strikers. The trammers formulated demands on the company for $60 per month, trammers to quit at 11 A. M. Saturdays, same as miners, and the day shift to consist of four gangs, instead of three; men loading electric haulage cars to change with those working old-style tramming alternate weeks; pay of trammers' laborers and rock house men to be $2 per day, instead of $1.80 or $1.90, as now; any man discharged for connection in this strike, all to quit. Later the company offered to compromise and pay $60 for January and $57 hereafter. The men refused, but it is thought the compromise may be accepted.

The reverberatory building of the new smelter at Houghton is roofed in. The building will contain five furnaces.

Keweenaw County.

The new shaft at the Allouez mine, near Allouez, underway, known as No. 1, has reached depth of 365 feet. The additional depth made during December was 75 feet. The Kearsarge lode is expected to be cut at depth not to exceed 1000 feet. A crosscut can be extended from the 30th level east to the lode, a distance of 150 feet, thus affording 200 feet of stoping ground before going to the Ahmeek boundary. One extra head will be available at this plant after the Centennial requirements are provided for.

The 1903 production of the Mohawk mine, near Allouez, was 6,500,000 pounds of refined copper, and with the aid of the third stamp the production of the mine is expected to be increased by 50%. The third Mohawk head is completed, but will not be put in operation until No. 4 rock house is ready (about Feb. 10).

The building of the rock house at the St. Clair shaft of the Phœnix mine at Phœnix is under way. The shaft is down 1710 feet. Shipments are being made from the stock pile at this shaft in addition to mill shipments from west vein shaft.

MISSOURI.

Jackson County.

The Apple Tree M. Co. has developed a lead mine in the Kansas City bottoms, says the News-Herald. Ore is being hoisted from a depth of 60 feet. A small pump handles the water. A turn in of 15,000 pounds per week is made. J. Myers is part owner of the Apple Tree.

Jasper County.

In sinking a shaft on the Cunningham land at Chitwood the Maybelle M. Co. has opened up a tiff cave at depth of 132 feet. Sinking below the cave the company has struck a body of ore of disseminated tiff and flint. They have a sub-lease of eight lots. J. M. Martin, E. Jenkins and J. M. H. Young are interested.

The Chicago Zinc & Lead Co., R. E. Sanford superintendent, has put up a building and steam hoist, preparing to putting machines to work in the ground. The mines are on the Portland ground north of Webb City. —— C. E. Mathews and W. W. Wampler have bought the Cumberland mill on the Bankers' ground, and will move it to their 20-acre lease on the Kelley ground north of Joplin, where they have a shaft down into ore.

Qualls, Mooneyhan & J. Gray of Carthage have a 56-acre lease 2 miles north of Carthage, on which they report striking a 25-foot face of ore in the first drill hole at 120 feet.

J. W. Kerr has struck a jack prospect on the Acme land south of Webb City and is having a shaft sunk. —— M. C. Terry reports there are two new mills going up on the Aylor ground at Alha.

E. H. Mower, W. P. Leon and O. H. McKinnon have organized the Hohoken M. Co. at Joplin. —— On the Williams land, 2 miles west of Carthage, J. W. Aylor and R. A. Bowen, lessees, have opened up a drill hole strike showing lead and zinc from depth of 30 feet to 78 feet. It is intended to continue the drilling to depth of 160 feet.

J. B. Daniel, manager of the Sphink and Ruby Neck mines at Neck City, says all the interests of his companies are sold to G. L. Cole of Neck City for Eastern men.

MONTANA.

Fergus. County.

The Judith M. Co., operating the Surprise group in Gilt Edge district, near Lewistown, is increasing development work. A tunnel was started at the base of the mountain in November and is in 200 feet. In this tunnel a body of cyanide ore of low grade, but of sufficient value to make working profitable, has been cut. In another tunnel, farther up the hill, another body of higher grade ore is shown, says Superintendent W. E. Wilson. A mill will be built during the coming summer.

Granite County.

Machinery for the mill being built by the Willow Creek M. Co., near Phillipsburg, is on the ground. The mill will be ready for operation by March 1st.

Jefferson County.

M. L. Hewitt, manager of the Cataract C. M. Co., in Cataract district, near Basin, says the smelter is completed and is expected to be in operation this week. Delay was caused by waiting for coke and coal supplies.

The Pennsylvania-Montana M. Co., operating the Hattio Ferguson mine, in Cataract district, near Basin, has placed its machinery and operations are under way. The number of men at work will be increased. The water has been pumped out of the shaft.

Lewis and Clarke County.

It is expected operations will be resumed at the Whitlach-Union mine, under bond to Canol & Martin of Helena. The Whitlach-Union is 4½ miles from Helena. They will sink 500 feet, going down on the dike. The ores are free milling. Canol & Martin have two shifts of men developing the M. & N. group in Ontario district, which group includes the Sure Thing mine.

They are nearing the 300-foot level, where station will be put in and crosscuts run from it. The shaft was sunk on the lead and the vein is 35 feet wide.

On the Big Indian mine, near Helena, development work is progressing. The company will develop it to depth of 1000 feet. Besides the 1000-foot shaft to be sunk on the largest vein two tunnels are being run, one to be driven 1200 feet to tap the main veiu at depth of several hundred feet below the present workings. It was expected to run this tunnel at least 700 feet before striking any ore body, but a vein was cut at distance of 150 feet which was previously unknown.

Madison County.

The Alder M. Co., operating on the Kearsarge and Rough Rider mines at Summit, near Virginia City, is pushing work on its mill and cyanide plant, and it is expected the machinery will be in operation by March 15. The company has sixty men on the payroll, besides forty miners who are further developing the Kearsarge. Two tunnels will be run. One will be driven 1500 feet to crosscut several veins known to exist. The other tunnel will follow the vein of the Rough Rider and will run in 1000 feet, developing the mine to depth of 750 feet.

The Dakotah M. Co., which is operating a group of mines in Hungry Hollow, has bought the General Shafter mine, near the Kearsarge mine, near Virginia City. Men have been put to work and will develop it. There is a 5-stamp mill and cyanide plant on the mine, the capacity of which will be increased.

The Grant M. Co. is working the U. S. Grant and Fairweather mines, 1 mile from Virginia City. The company has forty men on these properties. Three carloads of concentrates were shipped last week to the East Heleua smelter, and further shipments will follow. There is a 15-stamp mill, concentrator and cyanide plant, the power for which is derived from two 60 H. P. engines.

NEVADA.

Eureka County.

R. A. & W. Laird are working men in the Williamsburg mine on Adams hill, near Eureka. They have sunk 65 feet and drifted 95 feet, and have 30 feet more to drive before tapping the body of ore, says the Sentinel.

Lincoln County.

F. R. McNamee of Salt Lake City, Utah, has a lease on the manganese mines, 14 miles east of Los Vegas, near De Lamar, and will increase development work. He has men on the Iron King claim. Averages from the surface give 42% manganese and 27% iron, says the De Lamar Lode. It is intended to sack and haul it to Manvel, Cal., a distance of 70 miles, from where it will be shipped to Chicago for practical test. It will be hauled to Los Vegas as soon as the railroad reaches that point.

The Quartette mine, at Searchlight, has reached its 700-foot level and drifting will be begun.

Nye County.

(Special Correspondence).--Active work has begun on the 63 miles of railway on the Tonopah-Rhodes route. There is considerable material on hand at Sodaville, and with fair luck the road ought to be in operation into Tonopah by June next. A. Tripp is superintendent.

Tonopah, Jan. 24.

The Mohawk-Alpine M. Co. has been organized, with headquarters in Utica, N. Y., by C. Y. Fuller, F. A. Cassidy, J. C. Breen, W. M. Van Auken and B. E. Shear, the last-named being manager. The holdings of the company comprise six claims near the Nevada-Alpine mine, near Tonopah. Work is under way and shows silver-lead ore. Below the outcrop a shaft has been sunk 25 feet and a crosscut run into the hill 27 feet.

The Toyabbe M. Co., which has been organized by Skelton & McCarthy, has bought a group of claims in the Toyabbe range, 80 miles north of Tonopah, 40 miles south of Austin, and west of the road between Austin and Belmont. These mines are said to be in the same mineral belt as the Ophir Canyon mine, 2½ miles distant. The main ledge is 6 feet in width, with a 12-inch streak on the foot wall that averages $55 a ton. This ore runs about 30% lead. The other 5 feet of the ledge averages 10% lead, twenty ounces silver and $5 gold per ton. The company proposes putting in a concentrating plant and a compressor plant in the spring. C. S. McCarthy is manager.

Storey County.

(Special Correspondence). — "Keeping everlastingly at it brings"—an occasional dividend. On Jan. 21 the Ophir M. Co., on the Comstock, declared a dividend of 25 cents per share, the first since Jan. 12, 1880—twenty-four years ago, during which time work has been steadily prosecuted. The company expects to continue the regular payment of dividends. In the old days on Pine Street, San Francisco, Ophir was the favorite with those who followed Fortune's fluctuations, for no matter what ups and downs of the other stocks, Ophir was always counted on as a good buy on which to make quick returns.

Virginia, Jan. 22.

W. G. Douglass, superintendent of the Alta mine, says it is expected the Alta shaft may be used in connection with contemplated deep work in the Gold Hill part of the Comstock.

The Ophir M. Co. at Virginia City last week received $20,184.61 as net proceeds of the sale of five railroad cars of ore shipped to the smelter, says the Virginia City Chronicle.

Washoe County.

E. & H. I. Olinghouse have their stamp mill at Olinghouse in full operation.

Manager Williams says the Williams mill is dropping its stamps on high-grade ore from his mine and from the Cabin and Gold Ledge mines at Olinghouse.

NEW MEXICO.

Grant County.

A body of copper ore is being worked by Ernest & Islas on their lease on the Aztec mine, near the Romero, at Santa Rita. Five shafts have been sunk on this body and the lessees are preparing to sink another one to depth of 150 feet. They are putting in a steam hoist and other improvements.

Guadaloupe County.

Gold-bearing placers are reported found on Revuelto creek, 18 miles east of Tucumcari, on the Rock Island Railroad. Three hundred men are on the ground. The formation is said to be of black sand.

Rio Arriba County.

W. W. Ingersoll of Santa Fe, operating in Bromide district, near Hopewell, will drive a 1000-foot tunnel on the Bromide mine.——The Strawberry mine, in Bromide district, has closed down temporarily.

At Bromide it is reported the Tusas Peak M. Co., owning and operating the Tampa mine, will build a mill in the spring. The Tampa shaft is down 270 feet and is being sunk deeper. Stringers from the vein are being cut in the shaft and crosscuts will be run from the 300-foot level to the vein.

Sierra County.

A ten years' lease has been given to the Bigelow G. & C. M. Co. on land surrounding the Warm Springs, 2 miles north of Hillsboro.——The new mill built by the South Percha G. M. & M. Co., near Hillsboro, is in full operation.

Socorro County.

The Tularosa Democrat at Estey City says F. Boner is preparing plans for a 50-ton smelter to test all classes of smelting ore. As soon as the test is made the company will build a smelter that will give them, with their other processes, a capacity of 400 tons a day.

The Mogollon G. & C. Co., which is working the Cooney mine at Mogollon, is running 120 tons a day through the concentrator, having doubled its capacity. Rolls are being used instead of stamps. Several concentrating tables have also been added. Machine drills have been put into the mine. Six tons of concentrates are being produced by the mill per day. In the mine a depth of 500 feet has been obtained and arrangements are being made to sink deeper.

Taos County.

E. Westoby is developing the Jack Pot mine on Goose creek, near Red River.——G. B. Crow is working on his group on Black mountain.——Men have been put to work by M. Carmichael on the Franklin placer, near Red River.——C. Purdy and W. D. Cannon are developing the Norway mine, in Road canyon, at Red River. They have cut a new lead.

OREGON.

Grant County.

It is reported Burbridge & Burch are preparing to work their placer property on Crane Flat, near Granite. They have incorporated the Oregon G. Dredging Co., of Spokane, Wash., with F. Burbridge, A. Burch, J. F. Herrick, D. T. Ham and M. A. Folsom as directors. The Crane Flat placers consist of 240 acres of dredging ground. The company will put in dredgers in the spring. The gravel is estimated to average 30 cents a yard. The dredger will have a steam plant capable of generating 150 H. P.

Ore shipments are being made from the Fourth of July claim, on Granite creek, 4 miles from Granite. The Fourth of July adjoins the Gold Hill group. W. Wade, S. Camp and J. C. Wooley are principal owners.

Lane County.

The 15-stamp quartz mill at the Lucky Boy mine, at Blue River, has been closed down pending removal to the new millsite. Twenty-five additional stamps will also be put up. The millsite is 100 yards farther down the mountain side than the old mill, where there is plenty of water for running the enlarged plant. Power for operating the mill will be furnished by the electric power plant which the company has built on the McKenzie river, 6 miles from the mill.

Union County.

At a depth of 280 feet a vein of coal is reported struck in an artesian well on the J. W. Townley ranch, near Union.

Wallowa County.

It is reported the Tenderfoot M. Co., near Joseph, will build a 20-stamp mill, with cyanide plant. A sawmill will first be put up to prepare lumber for the buildings.

SOUTH DAKOTA.

Custer County.

The shaft of the Black Hills C. Co., near Custer, has been unwatered and work resumed in the crosscutting toward the west at the 700-foot level. The work shows a body of copper and iron pyrites carrying values in copper and gold. J. B. Taylor is superintendent.

The Saginaw M. Co. will resume operations at its mine, 8 miles northwest of Custer, this week, says Manager Woodbury. The company owns claims in the same belt with North Star and Roosevelt mines. A shaft has been put down several hundred feet following a vein of milling ore. A steam hoisting plant has been put in.

Lawrence County.

Operations were resumed last week in the mines of the Horsesboe M. Co., near Deadwood, and ore is being received at its cyanide plant in Terry. The mill will be started this week. Shipments will be continued to the National smelter at Rapid City, which is again in operation after a temporary shut down.

A deal is pending in Yellow Creek district, south of Lead, for consolidation of Wasp No. 2 and the Alder Creek companies and other boldings, jointly connected, embracing 500 acres of ground. There are deposits of cemented and quartzite ore which are said to be amenable to the cyanide process. Beneath the quartzite there have been found several veins of free milling ore in the slates. W. R. Dickinson of Lead is manager.

A strike of ore is reported in the mine of the Queen of the Hills M. Co., in Whistler gulch, south of Central City. The ore is found in a vertical vein, and is free milling.

The air compressor has been set up at the tin mill of the Tinton M. Co. at Tinton. The mill will have a capacity of 125 tons of ore daily and is expected to be put in operation next week. The main workings are 2700 feet from the mill and the ore will be trammed to the mill by gravity. Another tunnel will be started lower down the hill, which will give a depth of 300 feet on the main ore vein. M. Lyon is superintendent.

Pennington County.

The mill of the Sunbeam M. Co., operating on Friday gulch, 7 miles northwest of Hill City, will be put in operation next week. The shaft has been sunk to a depth of 450 feet and crosscutting is being done east and west at the 300-foot level.

The Empire State M. Co. proposes to build a stamp mill this season. Its mines are near Palmer gulch, 5 miles east of Hill City. J. B. Stafford of Hill City is manager. Increased development work is being done, opening up more ore. A drift is being run east.

Work has been resumed at the J. R. mine, 4 miles east of Hill City. There is a shaft 260 feet deep following a vein of free milling ore. The lower workings are being unwatered preparatory to further development. An air compressor has been set up and other improvements made. F. C. Crocker is principal owner.

A stamp mill with cyanide annex will be built by the Lakota G. M. & R. Co. at the Grizzly Bear mine, 5 miles southeast of Hill City. Considerable ore has been blocked out. A hoisting plant will be put in.——The Clara-Bell M. Co. will increase the size of its mill this spring, says F. Herbert of Oreville, manager. The main ore shoot has been struck again in the shaft and a hoisting plant has been set up.

A test run has been made by the Mainstay M. Co. at Keystone in the Bismark mill. The shaft is 400 feet deep, with crosscuts at the 200 and 300-foot levels, which have opened up three veins of low grade free-milling ore.

TEXAS.

Shipments of crude and refined oils from the Beaumont (Jefferson county) and Sour Lake (Hardin county) fields during the year 1903 amounted to 15,000,000 barrels, says the Record. Of this, 7,572,849 barrels went from Port Arthur by steamer and barge to New Orleans, Atlantic coast points, Cuba, England and Egypt; 1,416,178 barrels by steamer and barge from Sabine Pass to foreign and domestic points, and 5,711,615 barrels shipped by tank cars to points in Texas and Louisiana, only a small percentage of the rail shipments going to States other than these two. From Jennings (Louisiana) 298,800 barrels were shipped during the year 1903 by rail. Combining the rail shipments with the water shipments, the total from Texas and Louisiana fields amounted to 14,999,442 barrels. The record of shipments by the Kansas City Southern Railroad for the year was not obtainable, nor a complete record of barge shipments from the Jennings field. Of the rail shipments, the Southern Pacific handled from Gladys (Spindle Top) 10,667 cars; from Beaumont 1663 cars; from Sour Lake 11,359 cars; from Jennings 1328 cars. Shipments from Sour Lake were not started until July, 1903. The Santa Fe moved 3833 cars from Beaumont. In computing the Southern Pacific shipments from Gladys and Beaumont, an average car capacity of 200 barrels is used. Most of the system cars shipped from Gladys and Beaumont are of 300 barrels capacity, while the private line cars vary from 160 to 200 barrels. At Sour Lake the 300-barrel system cars predominate. The same applies to Jennings. The Santa Fe system cars are of 225 barrels capacity. It is difficult to figure the completo production of the various Texas fields for the year 1903, owing to the great number of operators and diversity of interests, but estimates are stated as follows: Spindle Top, 6,500,000 barrels; Sour Lake, 7,000,000 barrels; Jennings, 500,000 barrels; Saratoga, 100,000 barrels; total estimated production, 14,100,000 barrels. Estimates of oil in storage range between 7,000,000 and 8,000,000 barrels, not including the 1,500,000 barrels in Southern Pacific tanks or Texas oil in storage at Eastern stations.——The Higgins Oil & Fuel Co. will increase operations at Batson. The company has bought nine acres near the new wells and two rigs are at work. Six-inch pipe has been ordered for a line from Batson to Sour Lake. This line will be used by the Higgins Co., the Paraffine Co., the Heywood Co. and other producers who have oil to pipe to Sour Lake. From Sour Lake to Beaumont the Higgins Co. will use the United Oil & Refining Co.'s 6-inch line, and from Beaumont to Port Arthur the line of the National Oil & Pipe Line Co.——The Heywood Oil Co. is sinking the first well on its Batson lease, within 200 yards of the flowing wells. The drill is nearing a depth of 1000 feet.

UTAH.

Beaver County.

The Estella M. Co., near Milford, is increasing development, says Manager Tarbet. The new working shaft, which has been started at a point near the ore body, is down 70 feet. The steam hoist is in place and the company will build a stamp mill, with an auxiliary cyanide plant.

A strike of copper ore is reported made on the Letitia group of mines, near Milford, assaying 7% copper, with values in gold and silver.

Cache County.

A strike of native silver ore, which also carries gold, is reported made in the ground of the Vipont M. Co. in La Plata district, 25 miles from Logan. W. A. Wilson of Salt Lake City is manager.

Carboo County.

Sunnyside camp is making greater output of coal from the two mines of the Utah Fuel Co. there than at any previous period. A full number of men is at work, with the experienced digger making $4 a day on an average, while the new men are averaging $3 for eight hours' work. Men are being turned away from Sunnyside, as the company has all the men it can work. Those for whom there is not room at Sunnyside when applying for work are sent to the other camps of the company at Castle Gate, Clear Creek and Winter Quarters. At Castle Gate, with the new men arriving from the several settlements where diggers are being recruited, there are 200 miners employed. Twenty-five additional men will bring the number up to normal.

Grand County.

Negotiations are under way for consolidation of the International C. M. Co. and the Dirigo-La Sal M. Co., operating at Basin, in the La Sal mountains.

Juab County.

A new shaft at the Eagle & Blue Bell mine, near Eureka, was started last week. Men are working from four levels, two shifts, raising and sinking, and as soon as connections can be made from the incline shaft the number will be increased. The management hopes to have the shaft down 700 feet by July 1. The shaft will go down 1300 feet from the mouth of the tunnel, 500 feet below the surface. As soon as the shaft reaches the bottom of the old workings stoping will start.

Salt Lake County.

The Highland Boy mine, at Bingham, is

said to be producing an average of 700 tons of ore per day, 550 tons of which go to the company's smelter in the valley. Work on the addition to the smelter is progressing.

The United States M. Co. will add a battery of lead furnaces to its copper smelting plant at Bingham, and plans are being prepared by G. K. Fischer, the company's mechanical engineer.

An Eastern company represented by A. V. Patten of Ogden has an option on the Castro group of mines at Bingham for $60,000, says the Reporter.

Summit County.

It is reported negotiations are pending for the sale to the Federal M. & S. Co. of the Silver King and the Daly West mines at Park City, both producers of silver-lead ore.

Tooele County.

Superintendent Raddatz of the Honerine mine at Stockton says he expects the milling plant to be put in operation by Feb. 15.

Uinta County.

C. O. Baxter of Salt Lake City, manager of the St. Louis Gilsonite Co. interests, on the edge of the Uinta reservation, says work is progressing on the line of railway to give outlet for product of their mines. The grading for the line, which extends from Camp Gulch to Crevasso on the Colorado-Utah strip—a distance of 50 miles—is expected to be completed by February 10th, when the company will have established direct connection with the Rio Grande railway. The Dragen ledge owned by the company is said to be 8 feet between walls.

WASHINGTON.

Ferry County.

(Special Correspondence).— The Hendryx cyanide process will be in operation February 1 at the Mountain Lion mine.—— The Quilp mine is working as usual and hoisting an unusually high grade of ore. ——The Knob Hill mine is making a raise from the 150-foot level to the surface. There are 4 feet of shipping ore in the face of the drift.——The Belcher, a copper-gold property, is being opened up. It is smelting ore, carrying a high percentage of iron and 30% sulphur.——Work is resumed on the Wauconda group.

Republic, Jan. 23.

Sinking on the Abe Lincoln mine, near Orient, has been started under contract for the Hibernian G. M. Co., incorporated to operate the Abe Lincoln and Bryan claims. Three shafts have been sunk on the Abe Lincoln ledge, which shows on the surface 100 feet wide, carrying gold and silver values. The Hibernian Co. is composed of Spokane, Wash., men, the officers being H. H. Martin, F. M. Morris, L. Hughes, J. Parry and A. E. Gallagher.

Manager C. T. Porter says the Golden Lion-Little Four mines will sink 200 feet on the 40-foot shaft before drifting or crosscutting.

Stevens County.

The Last Chance mine, near Northport, is hauling ore for shipment to the smelter, says L. P. Larson, owner.——Five furnaces are in full blast at the Northport smelter of the Le Roi (Rossland, B. C.) Co., and a sixth one is being remodeled for operation next month.

WYOMING.

Bighorn County.

A second oil strike in the Bonanza fields, near Bonanza, this month, is reported made by the Collins company, which struck a flow of oil at depth of 765 feet. The flow was ten barrels a day, but the well has been cased and drilling will be resumed to reach the second oil stratum.

Carbon County.

The No. 4 entry of the coal mine at Hanna is again afire and all men were taken from the mine until the fire can be subdued or walled in. The mine is not yet fully repaired from the explosion of last June. The fire is confined to a small area.

The Boncecovia M. Co. of Detroit, Mich., and Cleveland, Ohio, men, is preparing to prospect mining claims which it owns 4 miles north of Rawlins. A contract for 100 feet of work has been let. Assays on ore from this claim show copper and gold values.

Sweetwater County.

The Belgo-American Oil Drilling Co. has men at work drilling several wells for oil in the Salt Creek fields near Rock Springs, and operations will be continued through the winter. One of the wells is being put down by an English crew and the other is in charge of American drillers. The methods employed by the two crews are different and the results secured by each are being watched with interest.

Uinta County.

Evanston reports say oil and coal prospectors have been warned by the Union Pacific R. R. Co. that they must confine their prospecting in southern Wyoming to government land and make no locations on sections of the railroad grant. Locators insist that if they discover oil or coal they are entitled to a patent.

FOREIGN.

The British gold output for 1903, in ounces, compared with 1902, is reported as follows:

	1903.	1902.
British Columbia	....	*230,491
India	600,060	514,291
Transvaal	†2,677,088	1,707,661
Rhodesia	†15,711	17,918
Western Australia	†2,106,974	2,092,555
Queensland	909,900	860,153
Victoria	†711,710	777,738
New South Wales	†286,063	300,289
New Zealand	....	508,015
Tasmania	‡35,186	69,491

* Lode only. Placer gold: 1902, $1,073,110.
† Eleven months only.
‡ Six months only.

AUSTRALIA.

Queensland.

The Queensland returns for gold for December are reported as follows:

	Tons crushed.	Yield in ounces.
Charters Towers	24,300	35,300
Croydon	8,900	9,800
Gympie	10,400	10,800
Mount Morgan	20,300	9,500
Ravenswood	2,000	3,500
Other fields	6,700	6,800
Alluvial	....	1,900
Total	....	86,600

The total yield for the twelve months of 1903 was 909,900 ounces.

Western Australia.

The value of the government water system for Coolgardie and Kalgoorlie sections is shown by one mine's saving on the field, says the W. A. Journal. Fresh water pumped from Helena river is supplied to the mines at 5s per 1000 gallons through agency of company acting as lessee, which is the payee to the government under the agreement to buy 500,000 gallons per diem from the C.W.S. The purchased water in month of October averaged 520,000 gallons a day, or 20,000 above the contracted quantity. The mines on their part have to let run to waste the whole of the salt water pumped from the workings. The Ivanhoe mine last summer had a water bill of £76 per day; now it is £22 per day. The Bouldor and others of the larger mines are similarly assisted. One summer the mine had an outlay of £5000 a month for water. When the hot weather arrives the consumption, on account of evaporation, will, of course, be greater.

BRITISH COLUMBIA.

Boundary District.

Work was resumed at the Rathmullen mine last week, near Summit camp. G. E. Foster is principal owner.——The Hall M. & S. Co. has contracted for output of the Oro Denoro mine, in Summit camp, but the ore will be treated at the British Columbia C. Co's. smelter at Greenwood for the present.——Work on the Senator group, in Summit camp, is progressing and ore shipments are regularly made to the Granby smelter, which company has a bond on the mine. The ore has high percentage of iron, making it desirable for smelting.

P. McDonald and J. Sutherland, owners of the Elkhorn mine in Providence, last week made a strike of ore carrying gold and silver values.

East Kootenay District.

The John Bull group of claims, 3 miles above St. Mary's Lake at the Meadows, has been sold to L. A. Jarnagin of Spokane, Wash. Development work consists of a tunnel, in 60 feet, with 6 feet of copper ore showing in the face. Assays give 12% copper and $5 in gold. Jarnagin has has also secured the Dominion adjoining, a silver-lead prospect, showing 6 feet of galena on the surface and continuing 60 feet in depth. A second lead carries copper and gold values, and has a shaft down 62 feet in ore. Development work will be increased in the spring, under superintendence of Mr. Jarnagin.

At Wilmer it is reported the Ptarmigan mine has closed down.

The records of the Government office at Fort Steele show for the year 1903: One hundred and sixty-nine claims held under Crown grants or certificates of improvements; 335 certificates of work issued; 193 mineral locations recorded; total number of existing claims in Southeast Kootenai, 696. Eighty-seven transfers of mineral claims were made during the year. Number of free miners' certificates issued was 400.

Rossland District.

At the Rossland Power Co.'s 200-ton plant, near Rossland, to handle War Eagle - Centre Star ores construction is progressing. The main buildings are completed and the machinery is being set up. The management expects to have the works in operation by May 1.

At Le Roi mine, at Rossland, the output is being brought up to a basis of 24,000 tons per month. Much of this ore is being taken from the stope on the 800-foot level, where the face is said to be 80 feet in width. In the 1350-foot level development of the ore shoot is progressing.

Slocan District.

An impulse water wheel has been set up at the Alamo concentrator and crushing started.——Water pipes are being laid at the Rambler mine at McGuigan and hauling of coal will cease.——Men are at work at the Whitewater Deep mine.——The jigs in the Ivanhoe mill at Sandon are being changed from double to four-compartment, to handle the zinc values to greater advantage. The Slocan Star mine will do the same.

Three feet of galena has been struck at the Hope claim at Sandon. ——The lessees at the Republic group are making shipments of ore. The ore is being taken from the Bell claim.

Work is progressing on the L. H. mine on Red mountain, near Silverton. It is owned by Fingland, Tingling & Brand. Two tunnels have been driven and at the face of the drift there is a shoot of 18 inches of quartz which carries $40 in gold per ton. The ledge is 10 feet wide. There are two tunnels on the mine, the longest of which is in 500 feet. The first 150 feet of this is crosscutting, the balance drifting on the lead. The second tunnel is in 100 feet and will tap the lead. The mine is 3 miles from Silverton and 1½ mile from a wagon road.

West Kootenay District.

The Elwood Tinworkers' G. M. Co., Ltd., with main offices at Elwood, Ind., has bought a fourth claim in Lardeau district, being the Silver Dollar, near Trout Lake, which has a free milling vein opened for distance of 3000 feet. The Elwood Co. will build a mill on the Silver Dollar claim to handle ore from all its holdings.

The total amount of ore shipped from the Silver Cup mine, near Trout Lake, during the year 1903, was 976.12 tons, having value of $82,212.87. —— The total amount of ore shipped from the Nettie L. mine for the year 1903 was 1042.73 tons, having value of $57,678.54.

The shipments during 1903 from Ferguson camp fell behind those of 1902, owing to building of reduction works jointly by the companies owning the Nottie L. and Silver Cup mines, it being deemed wiser to await the completion of the plant than continue shipping under a high freight and treatment rate. The Silver Cup mine shipped 976 tons in 1903, with a value of $82,212. The Nettie L. sent out 1042 tons, with a value of $57,678.

At both the Lucky Jack and the Swede groups of the Great Northern Mines, Ltd., at Poplar, in the Lardeau, showings of high-grade quartz are being opened up. Mill tests made at the company's mill at Camborne have been completed on ore from both groups. One and one-half tons from the Lucky Jack — the ore being taken from both surface and underground workings—gave $150 per ton on the plates, says the Spokesman. Returns for nine tons from the Swede group gave $37 per ton on the plates. E. M. Morgan is superintendent. The initial month's run of the Great Northern Mines, Ltd., 10-stamp mill at Camborne produced $5000 on the plates from 500 tons. The ore was taken from the dump at the upper workings of the Rossland claim. A contract has been let for the completion of the Terminal tunnel to be the main outlet for both the Rossland and the Criterion veins. It is a crosscut and must be driven 400 feet before striking the main lode, giving depth of 250 feet. —— The Golden West and Crown King mines have been bonded to W. F. Teetzel et al. of Nelson, B. C., for $25,000. Development will be started in the spring.

Yale District.

Fourteen square miles of coal lands in the Nicola district will be developed, says W. Holland of Toronto, manager of a company of Eastern men who control the ground. It is said the coal mines were first proved several years ago by Government borings, which prospected 10 square miles of territory. This is said to have shown large bodies of bituminous coking coal generally in the valley to a depth of between 600 and 700 feet. Some of the veins are said to be 16 feet wide. The company has a charter from the Dominion Parliament and a bonus of $6400 per mile to build a railroad. The road will connect with the Canadian Pacific railroad at Spence's bridge. Surveys are said to have shown that a 1% grade can be secured for the entire 50 miles between Spence's bridge and Nicola lake. The line will follow the course of Nicola river and gives access to mines at junction of that stream with Coldwater river. In addition to the coal there is said to be a number of copper claims which will be reached by the road, and a hematite deposit. It is planned to build coke ovens at the coal mines.

CANADA.

Ontario.

The Canadian Manufacturer says for some time past the government of Ontario has had under consideration the question of withdrawing from sale or lease all the known unsold nickel lands in the Province and offering them to the Imperial Government to provide war material for the manufacture of armor plate and British guns. The order in council of November 11, 1903, withdrawing a belt of land 10 miles wide on each side of the Temiskaming and Northern Ontario Railway, to reserve the minerals, especially the nickel ores, is the first step toward making possible British ownership of the nickel of Ontario.

INDIA.

The output of the gold mines of India by months for 1903, compared with 1902, is given in ounces as follows:

	1903.	1902.
January	48,080	41,612
February	46,268	40,053
March	48,327	41,575
April	48,271	38,329
May	48,628	28,063
June	48,980	37,166
July	50,571	42,847
August	50,286	49,628
September	51,452	49,420
October	52,724	47,858
November	52,016	48,332
December	54,157	48,078
Totals	600,060	514,291

The principal producers for month of Decombor were:

† Including 1039 ounces from plates.

MEXICO.

Chihuahua.

The Batopilas M. Co., owning a mineral concession of 69 miles square near Batopilas, in district of San Andres del Rio, has five properties in operation—the Porfirio Diaz tunnel, and the San Mignol, Todos Santos, Camudin and Descubridora mines. The Porfirio Diaz tunnel is in 7000 feet. Five shafts are also being sunk, four being incline and aggregating depth of 3750 feet, and the other is vertical with depth of 700 feet. The underground workings are said to total 44 miles. The vein is 3½ feet in width, the ore carrying native silver and sulphide. Equipment consists of a 75-stamp mill (800-pound stamps), a 25-stamp mill (900-pound stamps), nine table concentrators, six single hoists, two of which are steam and the other four gasoline, four boilers, two 14 H. P. electric generators for lighting the mines, mills, camp, etc., one roasting furnace and lixiviation plant with capacity of ten tons per twenty-four hours, one amalgamation plant consisting of eight pans 3½ feet in diameter, and four settlers. Another twenty-five stamps are being added to the 25-stamp mill, which are expected to be in operation by Feb. 1. Both mills are operated by water power, water being brought in an aqueduct 2½ miles long, and generating total of 350 H. P. The 75-stamp mill is equipped with foundry and machine shop. The mines are 250 miles from the nearest railroad, and all supplies are brought in by mule train.

Guerrero.

Thirty-two kilometers west from Chilpancingo, and in Bravos district, the Delfina M. Co. is operating La Delfina group of mines. Development consists of one inclined shaft, down 100 meters, and of one tunnel, in 390 meters, says the Mexican Investor. The high-grade ore, sulphide of silver and antimony (pyrargyrite), is said to run $400 silver per ton. This ore is shipped for treatment. The low-grade ore is treated by the 5-stamp mill and concentrators on the ground. The company is putting in a 25-ton-per-day

smelting plant which will handle the high-grade ore.

Los Tres Aztecas y Anexas M. Co. has taken over and is operating the Calandria, Montezuma, Cierro Altos and Mercurio claims, in Alarcon district, 16 kilometers northeast from Naranjo station, on the Mexican Central Railroad. These mines are tunnel propositions. Three tunnels are being driven — two from opposite sides of one of the mountains on the group, and one is being driven into another ridge. The first two are being driven to meet at a common point and are expected to tap the ore bodies at depth of 400 feet below the old workings. The other tunnel will tap the ore bodies at depth of 700 feet below the previous workings. The ore is said to carry lead, silver, iron and some gold.

Jalisco.

(Special Correspondence).—The owners of the Bolanos mines are working ore running fifteen ounces in silver per ton. The ore also carries high percentage of lead, with some copper. Several companies have tried to work the rich ores below the water level, but their pumping plants have proven inadequate.

Mexican gambucinos (prospectors) are working the tin veins north of Huejuquillo. They do their own smelting and sell their product in Zacatecas, where it commands about 58 cents per pound in Mexican currency.

Zacatecas, Jan. 15.

Michoacan.

At the Dos Estrellas mine, at Tlalpujahua, two tunnels are being driven and two vertical shafts sunk. The main or Dos Estrellas tunnel is in 835 meters, and the Cedro tunnel, the face of which is 1609 meters north of that of the main tunnel, is in 535 meters. The two-compartment north shaft is expected to tap the Cedro tunnel at depth of 250 meters and at a point 750 meters in. Should developments continue satisfactory, it is stated that the management will enlarge each of the shafts to four compartments and add another hoisting plant at each. They also propose enlarging the present single-compartment main tunnel to double-track width.

G. A. Evans of Telluride, Colo., says his company is preparing to build a smelting plant near Tejupilco.

The Jupiter M. Co. will put in pumping and hoisting machinery at its mines near Tlalpujahua, says A. E. St. Morris, superintendent.

Nuevo Leon.

Additional machinery will be put in by the Alamo M. Co. at its mines in the Montanas mountains, near Monterey. F. T. Howe is manager.

Oaxaca.

F. L. Freeman of Cincinnati, O., interested in the Frederico mine, near Oaxaca, says they are preparing to put in additional machinery.

Sonora.

(Special Correspondence). — Extraction methods will be improved in operating the Cinco de Mayo mine at Pilares de Tierras, in Moctezuma district. A railroad will be built from the mine to La Para, ou the Copper Queen Co.'s branch to Placeritas de Nacozari. The mine is owned by Gen. Garcia and is a chloriding proposition.

Nacozari, Jan. 16.

The Winona M. Co., which is developing a copper property—the Maravilla—in San Antonio Pass, 20 miles southeast from Nogales and 3 miles south of Washington Camp, has the shaft down 100 feet and is drifting for the ledge, which the shaft cut in going down, passing through 53 feet of copper ore.

G. Wyman, president of the Wyman M. Co., which is operating the Animas mine at San Javier, states that the concentratiou plant in course of construction will be ready for operation in April.

On the Dormido mine, owned by W. F. & H. K. Chenoweth, a strike has been made of high-grade gold ore. The Dormido is near the Providencia mine, owned by the same parties. They are 7 miles east from Cerro Prieto, in Magdalena district.

C. W. Phillips of the Rey de Oro M. Co., near Magdalena, says it is the intention of the company to build a 10-stamp mill on its mines.

The dredger of the Chicago & Sonora G. Placer M. Co., near Suaqui Grande, is reported to have resumed operations, says the Oasis. During the rainy season in July the boat was washed away, landing high and dry on one side of the scene of work.

At Arizpe, it is reported, a strike has been made of gold-bearing ore in the Las Chispas mine, owned and operated by J. Pedrazzini.

J. Henderson of Nogales, Ariz., manager of the Mina del Oro mines of Provenir de Sonora M. & M. Co., says he is preparing to build a pumping plant at Saucedo, 1½ miles from the mine, and also lay a pipe line. The mine is near Poza station on the Sonora Railway.

The American-Mexican M. & Dev. Co., G. Charters, manager, operating at San Ricardo, will lay pipe line and build pumping plant for the mill and mine.

Superintendent D. J. Duncan of the Hays Con. M. & M. Co., operating near Quipano, says the masonry work for the dam and the pump foundations is under way. A pumping plant and pipe line will be put in.

Tamaulipas.

R. Benevedo of Matamoras, who has leases on 500,000 acres of oil lands in Tamaulipas, reports he is, with California men, preparing to develop the holdings for oil.

NEW ZEALAND.

The gold returns for New Zealand for month of December is reported at 49,794 ounces, of value of £193,261, as compared with 64,071 ounces, value £248,293, in December, 1902.

RUSSIA.

The Russian Department of Mines reports the output of platinum in 1903 to have been 389 poods 3 funts, which is equivalent to 14,007 pounds, as compared with an output in 1900 of 310 poods 26 funts, or 11,183 pounds.

Personal.

R. J. CORY, manager, Denver office, Allis-Chalmers Co., is in Chicago, Ill.

H. B. HICKEY of Albion, Cal., is in San Francisco, Cal., on mining business.

E. K. SMART of Grass Valley, Cal., is in San Francisco, Cal., on mining business.

W. G. DOUGLASS is superintendent of the Alta mine on the Comstock, near Gold Hill, Nev.

W. BRAY of Placerville, Cal., interested in El Dorado county mines, is in San Francisco, Cal.

A. S. MORRISON has resigned as superintendent of the Noonday copper mine, near El Dorado, Cal.

H. W. TURNER has returned to San Francisco, Cal., from an examination of mines at Bohemia, Or.

M. M. GREEN, M. E., is professor of mechanical engineering at the University of Colorado, Boulder, Colo.

G. D. DOVETON of Denver, Colo., is at Torres, Sonora, Mexico, constructing slimes plant for Crestone Co.

A. C. KYLE is superintendent of the Bullion M. Co., operating on the Comstock, near Virginia City, Nev.

T. DENNIS has resigned as superintendent of the Adventure copper mine at Greenland, Ontonagon county, Mich.

M. J. LIDSTONE of San Francisco, Cal., has gone to San Bernardino county, Cal., to build a milling plant near Dale.

O. E. KIRKPATRICK of Leesburg, Idaho, superintendent of the Gold Flint mine, is in Chicago, Ill., on company business.

D. ELLIS is assistant mine foreman of Horseshoe M. Co., near Deadwood, S. D., and will have charge of the Hardscrabble mine.

S. BAMBERGER of Salt Lake City, Utah, is president and manager of the Lower Mammoth mine in Juab county, Utah.

W. W. ELLIOTT AND F. M. DRESCHER have opened an office in Prescott, Arizona, for examination of and reports on mines.

J. W. PENDER is manager of the San Diego, the Capitanena and the San Nicolas mines near Santa Barbara, Chihuahua, Mexico.

J. W. ASTLEY, superintendent of the Snowshoe mine at Greenwood, B. C., has gone to London, England, on company business.

SUPERINTENDENT S. TARBET of the Estella M. Co., operating near Milford, Utah, has been appointed manager of the company.

S. A. MARTINDALE is superintendent of the gold dredgers of the Folsom Dev. Co., operating near Folsom, Sacramento county, Cal.

B. C. BURNHAM, of Denver, Colo., will represent the Broderick & Bascom Rope Co. of St. Louis through the intermountain territory.

W. W. TINER has returned to San Jose, Cal., after a two-years' engagement with a Russian mining company operating in Mongolia, China.

W. R. MILLHAM, manager of the Interstate G. M. Co., is at Custer, S. D., to take charge of development work on the company's mines.

SUPERINTENDENT M. W. MATHER, of the Plumbago mine, near Alleghany, Sierra county, Cal., has gone East on company business.

J. DUDLEY is superintendent of the Eureka M. Co. at Santa Eulalia, Chihuahua, Mexico, succeeding H. Anderson, who is in New York.

W. LINDGREN of the United States Geological Survey has left San Francisco, Cal., for Cripple Creek, Colo., to complete the resurvey of the district.

T. H. OXNAM, manager of the Palmarejo & Mexican Gold Fields, Ltd., is at their mines at Palmarejo, Chihuahua, Mexico, from Los Angeles, Cal.

W. L. CLARK, till recently assistant manager of the Clark properties in Butte, Mont., has gone to Jerome, Ariz., as business manager of the United Verde C. Co.

J. MCCAFFREY, superintendent of the Polar Star mine, in Nevada county, Cal., returned to Grass Valley, Cal., last week from an extended stay in San Francisco, Cal.

D. P. GILLIS, recently foreman at the Snowshoe mine near Libby, Mont., has gone to Matagalpa, Nicaragua, to accept a position as mine foreman for the Leonesa M. Co.

J. R. DE LAMAR of New York, principal owner of the Bully Hill copper mines in Shasta county, Cal., and interested in mining properties in Nevada, is in San Francisco, Cal.

F. FIELDING, who has been assayer at the Con. Cal. & Va. mine, Virginia City, Nev., for thirty years, has resigned and will go to Los Angeles, Cal., to open up an assaying office.

E. F. STAPLES, of the assaying firm of Baverstock & Staples of Los Angeles, Cal., is investigating mining property in the Magdalena mining district of Sonora in company with H. Cohen of London.

EMERSON GEE returned to Los Angeles, Cal., from Culiocan, Sinaloa, Mexico, on the 20th inst., and went on the 25th on professional business to Culiocan and interior points of Sinaloa and Durango.

T. H. TRACY has resigned as general superintendent of the North American C. Co., Encampment, Wyoming, and accepted a position with the Allis-Chalmers Co. of Chicago, Ill., in their New York office.

C. W. CLARK of Butte, Mont., is general manager of the Clark holdings in Arizona, including the United Verde copper mines and smelter at Jerome, Ariz., the United Verde & Pacific railway and the Iron King mine and smelter, with offices at Jerome.

G. H. BARNHART, who was superintendent of the Ymir Gold Mines, British Columbia, during the first four years the property was in operation, until February, 1903, has been appointed resident manager to succeed R. M. Atwater, Jr., who resigned at the first of the year.

E. A. ASHCROFT, a metallurgist of London, England, who, with Prof. J. Swinburne, head of the Mining Institute of England, has been working on a new process for reduction of ores, is in San Francisco, Cal. Mr. Ashcroft has been examining mining properties in British Columbia.

H. P. EELS, president of the Bucyrus Co. of South Milwaukee, Wis., and S. L. G. Knox, general manager of the company, are in San Francisco, Cal. They have returned from an inspection of the work done by the gold dredging machinery furnished by them at Oroville, through the Western Engineering & Construction Co. of San Francisco, their Pacific coast representatives.

Obituary.

JOSEPH ARROWSMITH, a mining engineer of Oakland, Cal., aged 73 years, died on the 27th inst. He leaves a widow.

A. S. MERRY died near Swansea, Wales, on the 29th ult. He was a partner of Lord Swansea (H. H. Vivian) and was a celebrated metallurgist there.

J. FLOYD, a mine owner of Nevada county, Cal., died at Grass Valley, Cal., on the 16th inst., from a hemorrhage of the lungs. He leaves a wife, and was aged 52 years, a native of England.

W. H. GARDNER, a California pioneer, died at San Jose, Cal., on the 26th inst. Deceased was a native of Virginia, 74 years of age. He went to California in 1852, crossing the plains by ox team, and followed mining until 1883. Four grown children survive him.

G. W. WILSON, a pioneer miner and assayer of Cripple Creek district, Colo., died at Cripple Creek on the 18th inst. Deceased was 61 years of age, a veteran of the civil war. In 1890 and 1891 he served as Mayor of Breckenridge, Colo., and for several terms represented a ward of that city as alderman. He also served as State Senator. He is survived by two sisters.

SELWYNN M. TAYLOR, a mining engineer of Pittsburg, Pa., died in the Harwick mine of the Alleghany Coal Co., near Cheswick, Pa., on the 25th inst., being overcome with gas while leading a rescue party following an explosion of fire-damp. Deceased had planned and plotted the mine, and was called by the Alleghany Coal Co. as the man best fitted to lead the rescuers.

J. LEE, aged 74, a pioneer miner of Gilpin and Clear Creek counties, Colo., died at Central City, Colo., on the 9th inst., after an illness of two months. Deceased was one of the first to prospect Leavenworth mountain, and is said to have located the O. K., Argentine, Jenny Lynd and other lodes. He was a veteran of the Mexican war and leaves a widow and two daughters.

SHERMAN G. SACKETT died at Denver, Colo., on the 18th inst., aged 53 years, of Bright's disease. Deceased was chief clerk of the United States Mint in Denver under two administrations and was an expert assayer and metallurgist. He went to Colorado in the early 70's from his native State, New York, and settled at Georgetown. After leaving the Mint he took up mining again. He leaves a wife.

JOHN MALTMAN, interested in Nome, Alaska, mines, and a brother of President Maltman of the Maltman mine of Angels, Cal., was killed on the 21st inst. while stretching a guy wire to a smokestack on the engine house of the Maltman mine at Angels. While attempting to tighten the steel wire it touched the electric cable of the Union Light & Power Co., which carries 18,000 volts. Maltman was standing in a pool of water and the current was short circuited.

J. M. DOUGLASS, a pioneer mining man of the Comstock at Virginia City, Nev., died in San Francisco, Cal., on the 17th inst. Deceased was born at Georgetown, Scott county, Kentucky, Dec., 1819, the following year removing to Pike county, Missouri. He worked in the Wisconsin lead mines. He went to Nevada county, Cal., in 1850, and to the Comstock in 1866. He is survived by two brothers and a nephew, W. G. Douglass, who is superintendent of the Alta mine at Virginia City, Nev.

JOHN MORRIS, a coal mining expert, formerly of Youngstown, Ohio, died at Denver, Colo., on the 12th inst., due to liver trouble. When the coal mine explosion took place in the Vulcan Fuel Co.'s mines at New Castle, Colo., in 1896, he was sent by the Santa Fe Railroad, which company owned the Vulcan, to the mine to make a thorough examination as to the causes of the explosion. Deceased was at one time a candidate for the position of State Mine Inspector of Colorado. He is survived by a son.

Commercial Paragraphs.

THE Mine & Smelter Supply Co. of Denver, Colo., report sale of a De Remer water wheel for a 400 H. P. plant for Mexico and another to Idaho.

THE Jeffrey Manufacturing Co. of Columbus, Ohio, through its connection with the Ohio Malleable Iron Co. of the same place, are now in the field soliciting orders for high-grade malleable castings.

THE Economist Gas Engine Co., 519 Howard Street, San Francisco, Cal., has installed a 40 H. P. pumping plant for J. Golman & Co., Tulare, Cal., for irrigation purposes. They are also putting in several irrigation plants at Winters, Yolo county, Cal.

AT Sheffield, a suburb of Kansas City, Mo., on the 21st inst., at the foundry of the Weber Engine Works, was cast the base for an unusually large gas engine eight tons of molten iron being required to fill the mold. The engine will be exhibited at the St. Louis Exposition. It will be a vertical two-cylinder engine, 150 H. P., with fly wheel 72-inch diameter. With charcoal fuel, and a gas producer

attachmont, it will produce power as an electric generator. Tho completed engine will weigh sixteon tons.

THE American Process Co., 62 and 64 William streot, New York City, has installed a direct heat sand dryer for the Granite Brick Co. of Glens Falls, N. Y. They are manufacturers of brick under tho Huennekes system. They have also put in a clay dryer for the Chattahoochee Chemical & Mining Co., Girard, Ala., and a direct heat dryer for M. P. Hubbard & Co., Baltimoro, Md., to dry sulphate of lime refuse.

THE C. O. Bartlett & Snow Co., Cleveland, O., have orders for olevating and conveying machinery from the Iroquois Portland Cement Co., Ca[illegible], N. Y.: the Elk Rapids Portland Cement Co., Elk Rapids, Mich.; the Grasselli Chemical Co., Clovcland, O.; tho Struthers Furnace Co., Struthers, O.: the Sandusky Portland Cement Co., Sandusky, O.: the Sherwin-Williams Co., Clevcland, O.: the Cleveland Gas, Light & Coke Co., Cleveland, O.: the Farmers' Chemical Co., Clovoland, O.: the S. Lorain Coal Co., and also from the Rossland Power Co., Rossland, B. C., for mining machinery.

THE Fred M. Prescott Steam Pump Co., Milwaukee, Wis., report the following among their recent shipments: A vertical beam condenser with a capacity of 70,000 pounds of steam per hour, to the Denvor Tramway Powor Co., Denver, Colo., making three machines of this size shipped to them during 1903; a triple expansion mine pumping engine to the Republic Iron & Steel Co., with a capacity of 2500 gallons per minute against 500 feet head; a triple expansion mine pumping engine to the Clairton Steel Co., with a capacity of 2500 gallons per minute against 500 feet head; two large triple expansion pumping enginos to the El Oro Railway & Mining Co., Ltd., El Oro, Mexico, completing a large order; a compound and condensing mine pumping engine to the Clover Leaf Gold Mining Co., Roubaix, S. D., with a capacity of 1000 gallons per minute against 500 feet head; two large compound hoiler feed pumps to the Tennesseo Coal, Iron & Railway Co., Birmingham, Ala. Among recent orders they have booked the following: From the Penn Iron Mining Co., Vulcan, Mich., three triple expansion mine pumping engines, each with a capacity of 1200 gallons per minute against 500 feet head; one triple expansion mine pumping engine with a capacity of 1200 gallons per minute against 1000 feet head; two sinking pumps of large capacities: from the Cleveland-Cliffs Iron Co., two triple expansion miue pumping engines, each with a capacity of 1200 gallons per minute against 500 feet head; one triple expansion mine pumping engine with a capacity of 1000 gallons per minute against 500 feet head; from the Calumet & Pittsburg Development Co., Bisbee, Ariz., one triple expansion deep mine pumping engine with a capacity of 1500 gallons per minute against 1000 feet head; one triple expansion deep mine pumping engine with a capacity of 1000 gallons per minute against 1000 feet head.

Trade Treatises.

Marsh boiler pumps are the subject of section 1, Catalogue No. 11, issued by the American Steam Pump Co., Battle Creek, Mich.; full-page illustrations, sectional views, detailed descriptions, with price lists.

Catalogue No. 9, from the C. O. Bartlett & Suow Co., Cleveland, Ohio, illustrates and describes their make of interlocking shoulder-bearing chain belts, with detailed data, price lists of sprocket wheels, etc.

Circular No. 77 from the Jeffrey Mfg. Co., Columbus, Ohio, is devoted exclusively to illustrations and descriptions of the Jeffrey grab buckets, which will work in ore, mine-run coal, broken limestone, gravel and sand.

H. W. Johus-Manville Co., 100 William street, New York City, send a description of their asbestos-metallic theater curtains, and a sample of the asbestos cloth used in the manufacture thereof, a subject of present general interest.

Oro cars are the chief subject of the black and carmine catalogue of the Atlas Car & Mfg. Co. of Cleveland, Ohio, and in 101 pages of the finely produced publication no less than fifty-four styles of cars, such as used by mines, are shown, most of the illustrations and descriptions having a full page devoted to each. Other cars and devices for miners' use are also portrayed in excellent manner.

The Trenton Iron Co. of Trenton, N. J., have issued the following publications: "Wire Rope and its Application to the Transmission of Power, Etc.," information of a general character concerning wire rope, and its special applications to the transmission of power, suspension bridges, etc.: also matter relating to wire rope fittings, sheaves and tackle blocks; illustrated, and containing valuable tables giving the weight, strength, working load, bending stresses, etc., of the different kinds of wiro rope. "Wire Ropo Tramways," profusely illustrated and treating principally of the Bleichert system of wire rope tramways of which The Trenton Iron Co. aro the manufacturers and sole licensees on the American continent. This is a revised issue of their former publication on this subject, with new text and illustrations. "Cablo Hoist-Conveyors," wherein special attention is directed to the Laurent-Cherry patent system, which requires no fall rope carriers, and the Hall patent system with self-filling bucket, specially adapted to excavating. "The Application of Wire Rope to Surface and Underground Haulage," a reissue of the chapters on the same subject in their previous publication entitled, "Wire Rope Transportation in All Its Branches" (now out of print). Any or all of these will be mailed free of charge, to anyono interested.

New Patents.

DEWEY, STRONG & CO.'S SCIENTIFIC PRESS PATENT AGENCY, 330 Market St., S. F., has official reports of the following U. S. patents issued to Pacific Coast inventors:

FOR WEEK ENDING JANUARY 19, 1904.

750,043.—WASH BASINS—D. B. Allen, S. F.
750,044.—HARVESTER—W. V. Allen, Chico, Cal.
750,075.—CONCENTRATOR—W. G. Anderson, S. F.
750,149.—GRAIN CAR DOOR—J. Barry, Seattle, Wash.
750,153.—SHAFT HANGER—Bechtol & Manley, Tacoma, Wash.
749,835.—ELECTRIC SWITCH—W. J. Bell, Los Angeles, Cal.
749,896.—CABLE GRIP—E. J. Brown, Coalinga, Cal.
749,920.—PILE PROTECTOR—A. S. Cooper, Oakland, Cal.
749,957.—PILE STRENGTHENER—A. S. Cooper, Oakland, Cal.
749,723—TYPE WRITER—D. S. Dufur, The Dalles, Or.
749,853—MAKING BUTTER—J. Estep, Tacoma, Wash.
750,178.—UMBRELLA—H. Fesenfeld, Hoquiam, Wash.
749,782.—TRUNK STRAP—R. Forbes, Downieville, Cal.
749,898.—HOIST—C. V. Fowler, Los Angeles, Cal.
750,190.—COOKER—J. Henault, Los Angeles, Cal.
750,032.—HOOK PIN—E. C. Herring, Reno, Nev.
750,193.—WARDROBE—W. C. James, Cucamonga, Cal.
749,968.—MAST HOOP—A. Klatt, Collinsville, Cal.
749,901.—MATTRESS—F. J. Lewzey, S. F.
749,942.—PUMPS—R. J. Mullin, Seattle, Wash.
749,969.—PACKING—J. K. Munson, Houghton, Wash.
750,037.—GRINDER—J. B. Phillips, San Bernardino, Cal.
750,006.—STAMP MILL—G. C. Richards, Berkeley, Cal.
750,227.—GOLD SAVING DEVICE—L. Sachse, Los Angeles, Cal.
750,038.—ATTEMPERATING DEVICE—M. H. Shoenberg, S. F.
749,808.—HAMMER—Speer & Bowman, Los Angeles, Cal.
749,908.—WRENCH—F. Stuart, Ritzville, Wash.
749,954.—FURNACE—M. L. Trapp, Los Angeles, Cal.
750,133.—CURING FOODS—C. B. Trescott, Portland, Or.
750,144.—SAW SHARPENER—W. J. Winter, Christopher, Wash.

Notices of Recent Patents.

Among the patents recently obtained through Dewey, Strong & Co.'s SCIENTIFIC PRESS U. S. and Foreign Patent Agency, the following are worthy of special mention:

STAMP MILL.—No. 750,006. Jan. 19, 1904. G. C. Richards, Berkeley, Cal. One-half assigned to H. Murphy, San Francisco, Cal. This invention comprises a supplemental shaft with levers adapted to engage tappets which are loosely carried upon the stamp stems and which are retained in place by sufficiently stiff springs so that vertically reciprocating movements of the stems and stamps would be effected by the action of the levers upon these tappets, while the springs would yield sufficiently to prevent sudden strain caused by the inertia of the heavy stamps and stems, the lower spring also acting to prevent breakages in case any hard substance that cannot he broken falls between the stamps and the dies.

ATTEMPERATING DEVICE.—No. 750,038. Jan. 19, 1904. M. H. Shoenherg, San Francisco, Cal. This invention relates to improvements in means for heating air forced under pressure through a tuhe or nozzle, and pertains particularly to an improved air hlast hand piece for dentists and others. Its ohject is to provide a simple electrical heating apparatus wherehy air at any pressure or temperature may he instantly obtained hy the manipulation of a single combined cock and switch.

HARVESTER, THRASHER AND SEPARATOR.—No. 750,044. Jan. 19, 1904. W. V. Allen, Chico. Cal. This invention consists in the employment of a supplemental straw carrier extending heyond the usual main straw carrier, so placed as to receive the discharge from said main carrier and having a series of turnable and adjustable direction hoards and a supplemental fan hy which the hlast of air is delivered hetween the main and supplemental straw carriers and also through the spaces hetween the direction hoards. A closed hottom receives any grain which is thus separated from the passing straw and returns it to a supplemental auger located heyond the augers of the regular cleaning shoe, and hy means of the adjustahle hoards the strength and direction of the hlast through and hetween them is regulated.

Books Received.

"Metallurgical Analysis and Assaying," by W. A. MacLeod, director Government School of Mines at Charters Towers, Queensland, and Chas. Walker, lecturer at the Government School, has been received from the publishers. This treatise represents the work in a three years' course for students of mining schools. Part I treats of qualitative analysis, the preparation and properties of gases. Part II is devoted to qualitative and quantitative analysis. Part III, section 1, deals with laboratory experiments and assaying, the second section heing devoted to technical analysis. The work is very complete and will be found a useful treatise on the various subjects in which it deals. It contains many tabulated schemes for mineral determinatiou and for use in chemical work. 318 pages, illustratod. Price $4. J. B. Lippincott Co., publishers, East Washington Square, Philadelphia, Pa.

Latest Market Reports.

SAN FRANCISCO, January 29, 1904.

METALS.

SILVER.—Per oz., Troy: London, 25⅛d (standard ounce, 925 fine); New York, bar silver, 55⅞c, refined (1000 fine): San Francisco, 55⅛c; Mexican dollars, 42@42½c San Francisco, 44c New York.

COPPER. — New York: Standard, $12.75; Lake, 1 to 3 casks, $12.62½; Electrolytic, 1 to 3 casks, $12.50; Casting, 1 to 3 casks, $12.37½; San Francisco: $15.00. Mill copper plates, $17.00; bars, 18@24c. London: £56 10s spot per ton.

The copper situation shows a slight recession instead of the expected advance, possibly due to the failure thus far of Japan and Russia to engage in war. The price in Eastern markets ranges between 12½c. and 13c. The market is steady, however, and there is no evidence at present of a material change.

LEAD. — New York, $4.65; Salt Lake City, $3.50; St. Louis, $4.25 San Francisco, $4.50, carload lots; 4¾c 1000 to 4000 lbs.; pipe 6½, sheet 7, bar 5¾c; pig, $4.85. London: £11 11s 3d ℔ long ton.

SPELTER.—New York, $5.05; St. Louis, $5.00; London, £21 17s 6d ℔ ton; San Francisco, ton lots, 6¾c; 100-lb. lots, 7c.

TIN.—New York, pig, $28.25 @ 28.50; San Francisco, ton lots, 30½c; 500 lbs., 31c; 200 lbs., 31½c; less, 32½c; har tin, ℔ lb., 35@37½c. London, £130 5s; £127 15s spot.

PLATINUM. — San Francisco, crude, $18.00 ℔ oz.; New York, ingot, $19.00 ℔ Troy oz. Platinum ware, 75 @ 82c ℔ gram.

QUICKSILVER. — New York, $46.50@47.00, large lots; London, £8 7s 6d; San Francisco, local, $44@45 ℔ flask of 76½ lbs.; Denver, $48.00. Export, $42.00@42.50.

BABBITT METAL.—San Francisco, No. 1, 10c; No. 2, 7c; No. 3, 6½c; extra, 17½c; genuine, 31½c; Eclipse, 35c.

SOLDER. — Half-and-half, 100-lb. lots, 19.50c; San Francisco, Plumbers', 100-lb. lots, 16.50c.

ZINC.—Metallic, chemically pure, ℔ lb., 50c; dust, ℔ lb., 10c; sulphate, ℔ lb., .04c.

NICKEL.—New York, 50@60c ℔ lb.; ton lots, 40@47c.

ALUMINUM.—New York, No. 1, 99% pure ingots, 35c; No. 2, 90%, 30@34c.

LUMBER. — (Retail): Pine, ordinary sizes, $24.00@25.00; extra sizes higher; redwood, $28.00@30.00; lath, 4 feet, $4.50 @5.00; pickets, $21.00; shingles, $2.50 for No. 1 and $2.25 for No. 2; shakes, $13.50 for split and $15.00 for sawed; rustic, $28.00 @35.00.

NAILS.—This week the basic prices are: Wire, $2.77; Cut, $3.25. Meanwhile the nominal quotations per keg (list prices) are: No. 20d to 60d, Wire, $3.35; Cut, $3.55; 10d to 16d, Wire, $3.45; Cut, $3.35; 8d Wire, $3.50; Cut, $3.50; 6d and 7d, Wire, $3.60; Cut, $3.60; 4 and 5d, Wire, $3.70; Cut, $3.70; 3d, Wire, $3.85; Cut, $3.85; 2d, Wire, $4.10; Cut, $4.10. Special rates for carload lots.

LIME.—Santa Cruz, $1.25 country, $1.25 city ℔ bbl.

CEMENT.—Imported, $2.15@2.40 ℔ bbl.; California carload lots, $2.00 f. o. b. at works; small lots, $2.25 ℔ bbl. in sacks, 4 sacks to bbl.

STRUCTURAL MATERIALS.

IRON.—Pittsburg, Bessemer pig, $14.00 @14.25; gray forge, $13.00; San Francisco, bar, 3c ℔ lb., 3½c in small quantities.

STEEL. — Bessemer billets, Pittsburg, $23.00@23.50; open hearth billets, $23.00 @23.75; San Francisco, bar, 7c to 12c ℔ lb.

GENERAL SUPPLIES.

ANTIMONY. — New York, Cookson's, 7c; Hallett's, 6½c; San Francisco, 1000-lb. lots, 8c; 300@500-lbs., 8¼c; 100-lb. lots, 10½c.

POWDER.—F. o. b. San Francisco: No. 1, 70% nitro-glycerino, por lb., in carload lots, 15½c; less than one ton, 17½c. No. 1*, 60%, carload lots, 13½c; less than one ton, 15½c. No. 1** 50%, carload lots, 11¾c; loss than one ton, 13¾c. No. 2, 40%, carload lots, 10c; less than ouo ton, 12c. No. 2, 35%, carload lots, 9½c; less than one ton, 11½c. No. 2** 30%, carload lots, 9c; less than one ton, 11c. Black blasting powder in carload lots, minimum car 728 kegs, $1.50 per keg; less car lots, $2.00 per keg.

CAPS.—3x, $5.50 per 1000; 4x, $6.50; 5x, $8; Lion, $9, in lots not less than 1000.

FUSE. —Triple tape, $3.60 per 1000 feet; douhle tape, $3.00; single tape, $2.65; Hemp, $2.10; Cement No. 2, $3.00; Cement No. 1, $2.65, in lots of 3000 foet and up.

CANDLES.—Granite 6s, 16 oz., 40s., 11½c ℔ set; 14 oz., 40s., 10c.

CHEMICALS. — Cyanide of potassium, 98%–99%, jobbing, 23@24c ℔ lb.; carloads, 23@23½c; in tins, 30c; soda ash, $2.00 ℔ 100 lbs.; hyposulphite of soda, 3@3½c per lb.; caustic soda, in drums, 3@3½c ℔ lb.; Cal. s. soda, bbls., $1.20@1.40 ℔ 100 lbs.; sks., $1.05; chlorate of potash, 12@13c; nitrate of potash, bbls., 10c; caustic potash, 10c in 40-lb. tins; roll sulphur, 2½@2¾c; powdered sulphur, 2@3c; flour sulphur, French, 3¼@3½c; alum, $2.00@2.25; California refined, 1¾@2c; sulphide of iron, 8c ℔ lb.; copper sulphate, 5¼@5¾c; chloride of lime, spot, $2.50@2.75; sulphuric acid, in carboys, 66% B, 1¾@2c ℔ lb.; nitric acid, carboys, 8c ℔ lb.

BONE ASH.—Extra No. 1, 5@6c ℔ lb. No. 1, 4@5c.

COAL. — San Francisco, coast, yard prices: Wellington, $8.00; Seattle, $6.50; Coos Bay, $5.50; Southfield, $8.00. Cargo lots, Eastern and foreign: Wallsend, $7.50; Brymbo, $7.50; Pennsylvania, hd., $14.00; Scotch, $8.00; Cumberland, $13.00; Cannel, $8.50; Welsh Anthracite, $13.00; Rock Springs, $11.50, long ton; Colorado Anthracite, $14.00. Coke, $10.50 per ton in bulk, $13.00 in sacks; Sunnyside, $11.50, long ton.

OILS.—Linseed, boiled, bbl., 49c; cs., 54c; raw, bbl., 43c; cs., 48c; Lucol oil boiled, bbl., 44c; cs., 49c; raw, bbl., 42c; cs., 47c. Kerosene—Pearl, per gal., 21½c; Astral, 21½c; Star, 21½c; Extra Star, 25½c; Eocene, 24½c; Elaino, 27½c; Wator White, in bulk, 15c; Mineral Seal, iron bbls., 19c; wooden bbls., 21½c; cs., 25c; Mineral Sperm, cs., 26½c.; Deodorized Stove Gasoline, bulk, 17c; do., cs., 23½c; 86° Gasoline, bulk, 25c; do., cs., 31c; 83° Naphtha or Benzine, deodorized, in bulk, per gal., 13c; do., in cs., 19½c; Lard Oil, E W. S., bbl., 85c; cs., 90c; Neats-foot Oil, pure, bbl., 75c; cs., 80c; Sperm, crude, 50@55c; Natural White, 70c; Bleached, do., 75c; Whale Oil, cs., 50@55c.

WHITE LEAD.—Per lb., in kegs: 500 lbs. and over at one purchase, per lb., 6½c; less than 500 lbs., per lb., 7c; in 25-lb. tin pails, ¼c ℔ lb. above keg price; in 1 and 5-lb tin cans, 100 lbs. per case, ½c. per lb. above keg price. Dry Lead—In bbls., 1 ton and over, 6½c; do. in kegs, 7c.

RED LEAD.—500 lbs. and over at one purchase, ℔ lb., 6½c; less than 500 lbs., 7c.

LITHARGE.—Pure, in 25-lb. bags, 8@9c ℔ lb.

BORAX.—Concentrated, 6@7c ℔ lb; powdered, 8@10c; fused, 20@25c; crystal, 7c; calcined, 25c.

MERCURY.—Bichloride, ℔ lb., 90c.

MOLYBDENUM.—$2.00 ℔ lb.

CHROMIUM.—90% and over, ℔ lb., $1.00.

PHOSPHORUS.—American, ℔ lb., 75c.

SILVER.—Chloride, ℔ oz., 90c@$1.00; nitrate, 55c.

ALUMINUM.—No. 1., 99%, small lots, 37c ℔ lb.; 100 lbs., 35c; 1000 lbs, 34c; ton lots and over, 33c, Pittsburg. No. 2, 90%, small lots, 34c; ton lots and over, 31c, Pittsburg.

URANIUM.—Oxide, ℔ lb., $3.50.

(These prices are wholesale, f. o. b. San Francisco, unless otherwise noted.)

Steam Sinking Pumps.

The Miners' Sinking Pumps occupy a place distinctly unique. They are called upon to perform work under conditions entirely different from other class of pumps.

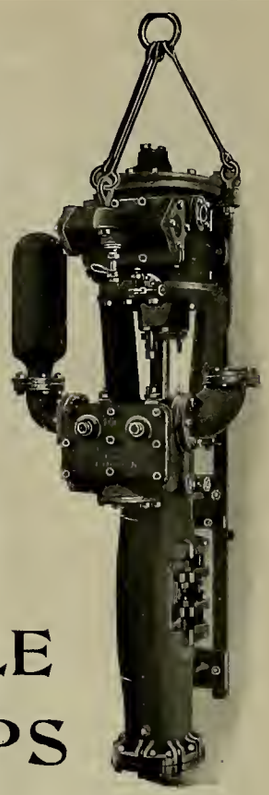
While steam economy, smoothness in operation are desirable features the commanding requirements of a first-class sinking pump may be cited as follows:

First—Absolute reliability of operation.

Second — Capable of pumping both air and water.

Third—Small space, accessibility of vital parts and lightness, yet of design and material to produce strength.

WRITE FOR ADVANCE SHEET NUMBER 12.



JEANESVILLE MINE PUMPS

ARE DESIGNED IN ALL SIZES FOR ALL KINDS OF METAL AND COAL MINES.

Jeanesville Iron Works Company

Mica Schist as an Ore Carrier.

Although veins in mica schist are for some reason looked upon with less favorable eye by the miner than some other classes of rock formation, yet quartz veins in mica schist have produced a large amount of gold, and in some districts the ore in mica schist is rich in gold. Ordinarily the veins occur as a succession of lenses or kidneys of quartz, and usually these have a tendency to follow each other in succession of lenses with a strike across the formation at a greater or less angle, determined by the direction from which the stresses producing the incipient folding were exerted. In some instances these lenses are short and narrow. In others in the same district they are wide and proportionally longer. In both cases, and particularly in the former, they often occur in a series of nearly parallel lenses forming a zone of mineralization. Where the compressive stress which caused the greater or less torsion of the rocks has been sufficiently great, folds have given place to abrupt fracture and a fissure vein results. In instances of this character a fissure, if followed persistently, will usually be found to merge into a succession of lenses which gradually become smaller and less distinct until all signs of crumpling or disturbance of the schistose structure disappears. This may occur within a few hundred feet or may extend for several miles along the strike of the formation. The prejudice against the downward extension of zones and lenses of gold-bearing quartz in mica schist is even stronger than that against its longitudinal occurrence. Numerous mines in this formation have been developed and proven profitable, but when the ore bodies in sight have been exhausted unless exploration has been carried on simultaneously which has developed new ore deposits, it is not uncommon to see such a mine closed with no further effort at development.

The fact that more than one lens has been discovered should prove sufficient incentive to seek for additional deposits, but as above stated the prejudice against this class of veins is fixed more or less firmly, and new discoveries are usually either accidental or made by men new in the business of mining. When mining in this formation the fact that the lenses break across the formation should not be lost sight of. A level driven straight ahead when a lens has been worked out may miss by a few feet, or even a few inches, another valuable deposit lying at one side or the other of the course of the drift. In these cases crosscutting is advisable, as it is in any mine, and neglect to give this important matter the attention it deserves may result in closing a mine of really great possibilities. The quartz found in lenses in mica schist is usually granular and glassy, and is generally classed as unfavorable to the occurrence of gold unless gold be seen in the rock, which is not infrequently the case. Very often the schist lying within the zone of mineralization is also gold bearing as well as the quartz lenses, though when this occurs a careful examination will disclose the fact that the schist has been silicified to a greater extent than is observable in the normal rock. There is one fact in favor of gold quartz occurring in mica schist in the form of lenses. It is usually free milling to a remarkable degree, but on the other hand, when the vein develops the fissure type of structure it is not uncommon to find complex ores—arsenical iron sulphide, galena, zinc blende and copper sulphide as well as pyrite. Rich ore also often results, but the rebellious nature of the ore to some extent offsets this richness.

Summarizing, it may be said mica schist produces erratic lenses and veins of quartz; that the quartz is above the average in value of gold quartz ores occurring under different conditions, but that the values are irregularly distributed, and that, although there have been many profitable mines in this formation, the large proportion of failures in mines opened in it may be charged rather to a lack of knowledge of the occurrence of ores in the schist than to the mines as representing a distinct or unreliable class.

Method of Securing Dump on Flat Placer Ground.

Securing Dump Room on Flat Ground.

The problem of securing sufficient dump and grade to admit of working placers on flat ground where there is abundance of water available is readily solved by the employment of hydraulic elevators, but where the quantity of water is limited to a small sluice head, the question must be solved by other means. The accompanying engraving shows how the difficulties were overcome at a placer mine in San Bernardino county, Cal. The gravel bed was opened by means of an inclined shaft, the incline being continued upward on a timber structure as shown. A car holding 16 cubic feet of gravel was used, and this was hauled from the face of the drift up the incline and onto the flat portion of the frame, in which bins were constructed to receive the gravel dumped from the car. A small portable engine and boiler furnished the power. The bins were provided with chutes which discharged into the sluice box constructed at the side bins. These were opened as required, and the water pumped from wells in the vicinity washed the gravel. When it was desired to clean up or to make any change in the line of boxes, the stream of water was temporarily diverted through a side gate, whence it flowed through a half-round flume made of disused pipe, to the wells. The movements of the car were controlled by a man stationed in the covered portion of the structure. The pile of rocks near the sluice was formed by pieces thrown out occasionally by the car man on the frame. The plant worked satisfactorily and might be duplicated to advantage under similar conditions elsewhere. The construction is simple, inexpensive and ingenious, showing that difficulties of this character may be overcome.

THE De Beers diamond syndicate, it is reported, has again advanced the price of diamonds. As the De Beers Company practically controls the diamond output of the world, there is little likelihood of a lower price obtaining in the near future. It is claimed that the constantly increasing expense in mining diamonds, together with the statement that the yield of the diamond-bearing ground is less than formerly, make an increase in price advisable.

INSTANCES are recorded where mining and milling have been or are being carried on at a cost so low as to surprise those who are well informed as to mining costs under varied conditions. In some of these instances it will be found that a large amount of dead work has previously been accomplished by the present or a former manager, which is now overlooked by every one except the manager himself, and as no charge is made for this work against the ore now being mined the mining cost seems strangely low, whereas, if the cost of the dead work were charged against the ore made available by this work, the cost would be raised considerably. Mining costs, to be valuable as a means of comparison, should take into consideration every proper charge.

INTELLIGENT use of the diamond drill in the gold mines of Western Australia has resulted, it is reported, in largely increasing known extent of ore bodies, the work of development having proved the discoveries made by use of the diamond drill to be correct and reliable. In that field the experiments with the drill have been made systematically, and the records kept have not been disproved by subsequent development. It was found, however, that in boring long holes the "drift" of the drill was considerable in some instances, and that until a series of holes had been bored the location of the ore cut by the drill was somewhat uncertain, but a series of holes systematically arranged makes it possible to determine the position of a body of ore with approximate certainty.

An Important Verdict.

The Coroner's jury, after investigating the occurrence at the Independence mine at Victor, Cripple Creek district, Colo., on January 26th, when fifteen miners were killed by overwinding of the cage, found the following verdict:

We, the jury, find that the deceased came to their end in the Stratton's Independence mine on Thursday morning, Jan. 26, through F. T. Gillese losing control of the engine there in use and pulling the cage into the sheave wheel, thereby parting the cable and precipitating the cage loaded with men down the shaft. And we further find that if the mine management had not neglected the usual precautions, the sad casualties might have been reduced, if not avoided. The usual precautions that were not taken are as follows:

First—No man was required to preside at the collar of the shaft while hoisting men.

Second—No safety device was in use on the cable to prevent the overwinding of the same.

Third—Men were loaded and unloaded without placing the cage on chairs.

Fourth—The disc brakes of the hoisting engine were detached from their usual position and therefore useless.

We, the jury, recommend that all safety appliances and precautions herein named and recommended be adopted and used not only by the Stratton's Independence mine, but by all mines in this district not now using the same, thereby reducing to a minimum the dangers to life and limb that men working in mines are subjected to.

We further recommend that a competent extra man should stand near the engineer while he is hoisting and lowering men, whose duty should be to render any assistance needed.

The above evidently indicates the state of mind in the community where the accident occurred. In the business of practical mining accidents are of frequent occurrence, and usually they occur in some new and unexpected way. This is always evident, for an accident which can be anticipated is usually avoided by the necessary precautions taken to avert it. In this case, however, from reports sent out by the local press it seems that the hoisting engine had previously given trouble, and in one instance an occurrence similar to that of January 26th happened, but before disaster resulted the engineer was enabled to operate the brakes and brought the engine to a stop. The several recommendations of the jury, if carried out, might, or might not, prevent a similar catastrophe under like conditions The requirement that a man be stationed at the collar of the shaft is a good one under ordinary conditions, but in an event such as occurred there recently, when the engineer was calling wildly for assistance and the engine winding at high speed with constantly accelerating velocity, it is difficult to imagine the top man standing at his post, or to see of what particular usefulness he could be under such circumstances. The second count, that "no safety device was attached to the cable to prevent overwinding," is a suggestion of doubtful utility. A hoisting engine usually possesses power far in excess of that necessary to lift the load it hoists from the mine. A clip, or other device on the cable, would scarcely have the effect of stopping the engine, while the strain on the cable would probably cause it to part the moment the safety device on the cable came in contact with some firm obstruction. The provision of bumpers on the guides to prevent overwinding would seemingly be a better device, when if the cage were provided with the usual safety clutches these would immediately operate, should the cable break, if the clutches were in good working condition, with a chance of holding the cage, as it had acquired no momentum. The third count, "Men were loaded and unloaded without placing the cage on chairs," has no apparent connection with the disaster, though chairs are always an advisable equipment and should be in constant use, as it is economy to employ them. The fourth count was "The disc brakes of the hoisting engine were detached from their usual position and were therefore useless." This charge presents a most unusual condition. Why the brakes were removed is not stated, but the fact of their absence appears to explain why the engineer was unable to apply these very necessary brakes and in this manner avert the catastrophe.

When cages or skips are run in balance, as in this instance, it is presumed that the cages have approximately the same weight. The shaft was about 1500 feet deep. The cages weighed, it is stated, about 4000 pounds. An inch and a quarter rope weighs 2.45 pounds per foot. When passing at the depth of 750 feet from the surface the weights are about equally balanced, the difference being in the weight of the men—in this case about 2000 pounds. As the upgoing cage approached the surface there was a difference of about 3600 pounds of cable in favor of the downgoing cage—1600 pounds more than that carrying the men. It is customary to shut off steam when nearing the surface, the additional weight of the down side, together with the momentum of the moving cages and rope, sufficing to bring the loaded cage to the surface, when it can be easily controlled by the brakes, if they are in working order, which, it appears from evidence in this case, they were not. It is presumable that a considerable interval had elapsed since the last hoisting trip had been made, and the engineer had no reason to suppose the brakes were not in working condition at the time of starting the skip from the lower levels of the mine.

Gold Dredging.

Dredging for gold within the past few years has become a distinct and important branch of the mining industry. This class of mining is carried on in gravel deposits where the situation admits of no other of the many mining methods being employed with a hope of financial success. The economical adaptation of the steam shovel to the handling of earth, gravel and finally to broken ore, demonstrated the economy of this means of handling large amounts of material at low cost. The experiment of dredging was tried by the employment of various devices. In some instances powerful pumps were used, which lifted gravel, water, and some of the gold as well, but they were soon superseded by bucket dredgers of various types. The first dredgers were considered expensive, costing $20,000 to $30,000 each, beside the cost of preparatory work in installation. Later a careful study of the requirements of the dredger suggested possible improvements. As a result dredgers were built costing $40,000 to $50,000, and it was found that these larger and more complete machines were more economical than the smaller and less expensive machines. Now dredgers are made costing $65,000 and over, and these machines, costing two and three times as much as the earlier dredgers, have been proven to be much more economical in operation than those of less cost and capacity. Elsewhere herein is an abstract of the annual report of a company operating near Oroville, Cal., in which many details of dredging operations are given. A comparison of the relation of values obtained in prospecting bore holes to results of actual dredging is interesting and instructive. The costs per cubic yard of material treated is also of interest, as these costs are segregated into the various branches and details of the operation. In New Zealand dredging is one of the most important features of the mining industry there. During November, 1903, nearly 100 dredgers were at work there, producing during three weeks working time 7216 ounces of gold. The cost per cubic yard of gravel handled for purpose of comparison unfortunately is not available.

The Battle for Copper.

The Supreme Court of Montana has reversed a decision of the lower court in the suit brought by J. MacGinnis vs. the Boston & Montana Copper Co. to restrain them from operating in Montana, for the reason that the Boston & Montana Co. was a corporation existing under the laws of another State, and as such was controlled by the Amalgamated Copper Co., and that the Amalgamated Co. had no right to hold the stock of another corporation under Montana laws. The Supreme Court has decided that no citizen has the right to maintain such action against such corporation, and that this right is vested in the State only; that the Amalgamated Copper Co. is neither a trust nor a monopoly, and that corporations may hold stock in other corporations, the same as individuals, and that the same is not contrary to the best interests of the State. A law was recently passed in Montana over the Governor's veto giving corporations the right to acquire and hold stock in other corporations and to vote the same. Unless the Supreme Court grants a new hearing on appeal, the accumulated dividends of the Amalgamated Co. will be disbursed. This is only another page in the history of the war for control of copper being waged between F. A. Heinze and the Amalgamated Copper Co.

CONCENTRATES.

BURLAPS wrapped about exposed water pipes will usually prevent the freezing of the water in the pipes. This is not proof against extreme cold, but is a good preventive against moderately low temperatures.

✤✤✤✤

IT is unnecessary to use bridging in shaft sinking except where the ground passed through is so soft that it requires the driving of lagging. It is occasionally put in in hard rock shafts, but it is an unnecessary expense.

✤✤✤✤

RAILROAD RAILS, with the bottom side turned upward, make a good grizzly. If the rails are separated by thimbles placed on the cross rods, those at the lower end being slightly wider than those at the top, it will have a tendency to reduce jamming of the rock between the rails, and the grizzly will more readily clear itself.

✤✤✤✤

ALL corporations operating in a State foreign to that under the laws of which the corporation was formed are required to have a resident agent at the capital of such State, who must have a power-of-attorney from the directors of the company. This agent usually is an attorney who acts in a similar capacity for several companies.

✤✤✤✤

THE posting of a notice by the owner of a mining claim under bond to an individual or a company, in which the owner disclaims all responsibility for debts contracted by the operators, is not required by law, but is a method usually adopted by the property owner to prevent attachment of his property in case debts are incurred by the bond holders.

✤✤✤✤

WHEN nitrogen is passed over a highly heated mixture of potassium carbonate and carbon the nitrogen is absorbed and potassium cyanide is formed, but the more simple method of making it is by heating potassium-ferro-cyanide, which breaks up into potassium cyanide and ferrous cyanide. The latter is decomposed by the heat into carbide of iron, the nitrogen being set free.

✤✤✤✤

WHERE it is desired to make curves in the line of track passing through a stope in which the square-set method of timbering is in progress, the posts may be set at a greater distance apart where necessary than the regular distance, the timbers being cut particularly for each place. If the ground is heavy, a line of poles may be laid back of the posts along the track and the space back of it filled at once.

✤✤✤✤

THE main gangway of a drift mine should be cut into bedrock to a depth of 2 or 3 feet. This serves a double purpose. It makes loading of cars from platforms along the drift more easy and consequently economical, and it makes it possible to ignore inequalities in bedrock surface, while maintaining a uniform grade for the track. This applies more particularly to drift mines of comparatively small width of channel.

✤✤✤✤

ONE of the most difficult problems facing the drift miner is the proper location of a tunnel site to reach the channel of an ancient river by driving through the rim rock. In most cases the tunnel driven for this purpose, where sufficient data has been unobtainable, has been found too low, and when the gravel was finally reached it was impossible to sink in the gravel owing to large amount of water encountered.

✤✤✤✤

IN the treatment of sulphide gold ores direct by cyanidation the success of the operation depends so far as observed upon the fineness of crushing of the material to be treated, and upon successful agitation of the sulphides during treatment. The cheapest method of reducing concentrates to a sufficiently fine state of division is a matter for experiment. It is believed, however, that this can be accomplished more satisfactorily and cheaply dry than wet.

✤✤✤✤

A TEST for the presence of silver in ores may be made by treating a quantity of the ore in boiling nitric acid, add water and when the solution is clear add a few drops of hydrochloric acid or a solution of common salt, and any silver present will be precipitated as a white cloud or as flakes of white chloride of silver. If the ore be chloride of silver, its presence may be detected by treating the ore with a solution of hyposulphite of soda, which dissolves the silver chloride. It is precipitated by calcium sulphide. Chloride of silver is soluble in ammonia.

✤✤✤✤

THE "cut" need not be drilled in the center of the shaft while sinking. It can as well be drilled nearer one end or the other. In a three-compartment shaft three machines, each on a separate bar, may be used, one at each end and the third near the center. The center machine and one of those at an end can be used to drill the center of the cut and the end holes, and the other machine to drill the down holes at that end of the shaft. In some instances four machines have been used mounted on two bars and a full round drilled with a single setting of the bars.

✤✤✤✤

WHEREVER gravel lies upon a "false bedrock" in the bed of a stream, it is reasonable to suspect the existence of older gravel below the false bedrock. This false bedrock may be a bed of conglomerate, a bed of calcareous travertine, a bed of hard clay mixed with pebbles and other rock fragments, a sheet or flow of volcanic rock such as basalt or andesite, or a bed of indurated sand of either volcanic or fragmental crystalline rock. It does not follow, however, that the old channel should be found directly beneath the newer one, and the failure to discover it there does not positively indicate that no older channel exists either to one side or the other.

✤✤✤✤

COPPER DEPOSITS are not confined to any particular geological age, but occur in rocks of almost any age and in many different kinds of rock. The United Verde mine of Arizona is in slaty and schistose rock, with limestone, all of pre-Cambrian age. Those of Butte, Mont., are in granite; those of Missouri are in Carboniferous limestone; those of Bingham district, Utah, are in porphyry and limestone; those of Cananea in similar formations. Many copper deposits are in diabase and diorite, or in schists altered from those rocks. The copper deposits of Paradox mountains, Colorado, are in sandstone. Copper also occurs in serpentine and in quartz porphyry.

✤✤✤✤

THE cost of obtaining a mining concession in Mexico is estimated at from $120 to $300 Mexican silver, divided as follows: Fees to mining agent, with acknowledgments, $20; publication of advertisements, $2 to $5; surveyor's fees, $25 to $200; expenses of trip to the mine not exceeding 10 kilometers (about 6 miles) and labor on survey, $15 to $25; stamp tax on five pertenencias, $50; deed tax, $2. To procure any number of pertenencias less than five will cost about as much, and a larger number may be reckoned as costing from $15 to $25 each in addition to the figures above given. The average cost, where a large number of claims are taken, is about $15 Mexican silver.

✤✤✤✤

THERE is a difference of opinion among mill men as to the advisability of dividing the plates in front of the battery. Some claim this arrangement to be an advantage in dressing plates and permitting a saving of time. Others hold that the comparatively small amount of time saved is more than offset by the loss occurring when all the pulp from the battery is run over one-half of the plate surface and that divided plates have no advantages. The same difference exists as to drops in the plates. Some contend that drops of one-half inch are a distinct benefit, having a tendency to render the quicksilver active. Undoubtedly amalgam accumulates where these drops occur if the drop be not too high. Whether there is a loss caused by this arrangement is a matter of differing opinion among mill men.

✤✤✤✤

THE Federal Statute provides: "Upon a failure to comply with these conditions (provisions defining method of making location, marking corners on the ground by means of posts or monuments, annual assessment, etc.) the claim or mine upon which such failure occurs shall be open to relocation in the same manner as if no location of the same had ever been made; provided that the original locator, his heirs or assigns, or legal representatives, have not resumed work upon the claim after failure and before such location." A, having resumed work through his agents before B made his location, debars B from claiming the ground and it is unnecessary for A to make a new location. The claim is as much in force as though he had done the assessment as required by the statutes during all the years following his date of location. The assessment work, however, to the amount of $100 must be completed.

✤✤✤✤

STREAMS and springs in the mining regions are often charged with ferrous and aluminum sulphates, resulting from the decomposition of bodies of sulphide ores. Where much iron is present a deposit of iron oxide is found on the rocks of the gulch, and this iron sometimes forms a firm bed of cement which may extend a long distance down stream from the source of the deposit. The water from such springs is usually remarkably clear and crystal-like, but is unfit for drinking or other use, being strongly astringent. The exploration of the vein or deposit from which the water issues will usually discover a deposit of iron sulphide, and in some instances copper as well. At Copper basin, Yavapai county, Arizona, the rocks of the streams tributary to the copper-bearing veins are coated with green copper carbonate, and nearer the source of the copper water copper carbonates have been deposited in the loose gravel, forming workable deposits of copper ore, upon which much development work has been done.

✤✤✤✤

THE saw is too large for the power. Try a 26-inch. A flywheel furnishes no power, but it tends to maintain a more steady running of machinery operating under a variable load, as in the case in point. When a shaft is sufficiently large for the strains put upon it, there is no good reason for increasing its size. The amount of power transmitted by a belt depends upon the relative diameter of the pulleys, and speed at which the belt travels, as well as upon the width of belt. The character of the pulleys is also a factor. Leather covered pulleys will transmit more power than those having turned cast-iron faces. A 4-inch belt is large enough for the equipment and could be used with more power than the present engine generates. It is believed that the product of oil refineries known as distillate is superior to gasoline, as it requires less in bulk, gives a stronger action in the engines, is less dangerous and costs about one-third the price of the former.

✤✤✤✤

THE fundamental principles of stadia measurement are based on the fact that parallel lines subtending the same angle from a given point are proportional in length to their distances from that point. This principle is applied by placing two horizontal hairs in the barrel of the telescope of a surveying instrument, equi-distant from the central cross hair. These are usually set at a distance from each other which will just cover a given length of a rod held in front of the instrument at a given distance. For convenience this is usually 1 foot of the rod at a distance of 100 feet from a point in front of the object glass of the instrument, which is equal to the focal length of the glass—that is, the distance from the cross hairs to the object glass. This distance, plus the distance from the center of the instrument to the object glass, must be added to all distances measured by stadia, whether long or short. Where distances are measured by this method over hilly ground, tables are supplied by instrument manufacturers for making the necessary correction for angles. By using care and not attempting too long measurements, the results of stadia work are as accurate as chaining over rough ground.

✤✤✤✤

SEVERAL of the mining States and Territories have passed mining laws which in most cases require the performance of certain acts in addition to those imposed by the Federal statutes. It has been contended by some that the States and mining districts have no authority to pass and enforce such laws. Secretary Teller expressed doubt whether a State Legislature had any right to attach additional conditions to the requirements of the United States laws, but Commissioner Williamson held that such requirement is not in conflict with congressional law. The State courts have uniformly enforced this class of provisions, and, there being no authoritative ruling denying the right of the State to make such legislation, it is assumed these conditions are valid. Several States have laws which require the sinking of a discovery shaft or its equivalent prior to the completion of location. These States are Arizona, Colorado, Idaho, Montana, Nevada, New Mexico, North Dakota, Oregon, South Dakota, Washington and Wyoming. The Circuit Court of Appeals for the ninth circuit (case of Northmore vs. Simmons, 97 Fed., 386) decided that it was competent for the laws of a State or the local regulations of a district to increase the amount of actual work required to hold a mining claim by the Federal law, and upheld the validity of the regulation.

✤✤✤✤

IN rock exposures the jointing planes are sometimes mistaken for planes of bedding. In some instances the distinction may be important. Where exposures of large extent may be studied, there is seldom any difficulty, as the floors produced by the joints are rarely, if ever, parallel, though often nearly so. Frequently the jointing planes are distinctly marked while the bedding planes are almost wholly obliterated, and in such cases the floors may be mistaken for planes of sedimentation. There are instances where the bedding planes stand nearly vertical, due to uplift of the formation, and in this ore deposition has taken place, but the floors formed by the jointing planes seem to have influenced the deposition of the ore, which is confined within irregular but distinct limits between floors lying a considerable distance apart, with several intervening floors which have no apparent effect on the ore deposition. In such instances the ore appears confined to a zone more or less irregularly defined by what may be considered the walls of the vein. These occurrences are erratic and cannot be anticipated, either as to the finding of ore or its discontinuance when found. In a mine where these geological peculiarities occur the necessary requirement is the discovery of an ore body large enough or rich enough to pay, though this may be said of any mine, but the occurrences above described are rather the exception than the rule.

✤✤✤✤

THE California Legislature passed mining laws in 1891 providing for proof of annual assessment, forfeiture of co-owners and resumption of work to prevent forfeiture. In 1897 another act, more comprehensive in scope and embracing some of the subjects embodied in the previous law, was passed. This act, by implication, repealed the act of 1891 to the extent that it embraced subjects covered by the prior law. This last named act was itself repealed by the act of March 20, 1899. The language being uncertain, it was contended that this last act did not repeal the act of 1897. The State Supreme Court held that the act of March 20, 1899, took precedence over all previous acts which were thereby repealed. On February 8, 1900, the State Legislature passed another act in which the language was free from objection, and which was practically the same as the previous act. The State law is still uncertain as to recording of annual assessment work. It requires the performance of assessment work, but imposes no work in addition to that required by the Federal Statute. Section 1159 of the civil code contains the following: "Affidavits showing work or posting of notices upon mining claims may be recorded in the Recorder's office of the county where such mining claims are situated." The word "may" indicates that the recording of such notice of assessment work performed is optional and not compulsory. It is unlikely that the courts would sustain an attempt to forfeit a claim for failure to record such notice.

Cost of Gold Dredging Operations in California.

Following is an abstract of the annual report of the Oroville Gold Dredging & Exploration Co. of San Francisco, Cal., for the calendar year 1903:

BULLION TABLE.

MONTH.	Cubic Yards (Bank Measurement) Dredged.	Operating Expenses.	Cost per Cubic Yard, Cents.
January	*31,000	$ 1,712 77	5.52
February	*30,130	1,804 48	5.98
March	*30,570	2,895 99	9.47
April	49,130	2,684 32	5.46
May	35,900	2,273 46	6.33
June	34,040	2,667 87	7 83
July	40,100	3,017 13	7.52
August	46,000	3,884 83	8.44
September	46,790	2,529 99	5.34
October	50,960	2,574 56	5.05
November	39,420	2,530 64	6.42
December	40,570	2,208 91	5.45
Totals and averages	474,610	$30,784 95	6.48

*In January, February and March 44,680 cubic yards of soil dredged on moving dredge to block 196.

SUMMARY OF COST IN CENTS PER CUBIC YARD.

	1903.
Dredge Crew, Power and Operating Supplies	2.52
Repair Labor	.95
Repair Supplies	2 65
Total Operating Costs	6.10
Superintendence	.38
Oroville General Expense	.28
San Francisco General Expense	.17
Taxes and Insurance	.38
Bullion Expense	.04
Grand Total all Costs	7 35

For three dredges these items would he as follows:

	1903.
Dredge Crew, Power and Operating Supplies	2.52
Repair Labor	.48
Repair Supplies	2.58
Total Operating Costs	5.58
Superintendence	.16
Oroville General Expense	.09
San Francisco General Expense	.06
Taxes and Insurance	.24
Bullion Expense	.04
Grand Total all Costs	6.17

The above work was done with one $45,000 dredge uuder direction of Superintendeut C. H. Munro. The original inteutiou of the organizers of the company was to equip the property with three $45,000 dredges. This has not been done, as the $67,500 style of dredge since developed can haudle 60,000 cubic yards per month at a cost of about 6 cents per cubic yard. It is the iuteution of the company to now add one $67,500 dredge. With this and the $45,000 dredge it is expected to handle 100,000 cubic yards per month at a total average cost of 5.7 cents per cubic yard.

Weights of Steel and Iron, Etc.

TO THE EDITOR:—In looking over the table of weights of round, octagon and square steel given in your last number, out of curiosity I applied the old rules for memorizing for the purpose of getting at the approximate weights of bar wrought irou. I found that they agreed very well, after making allowauce for the extra weight of steel over iron. In doing that, however, I discovered a new rule that will give—uot approximate, but absolutely correct—weights of octagon steel to the third or fourth decimal place. As it may iuterest your readers, I give it below. It must be understood that the rule is given in the following form in order that it may be easily remembered:

Rule for fiuding the weight in pounds of octagon steel bars. The weight found is for oue lineal foot of bar. It is to be uuderstood that the diameter of the octagon is to be measured from face to face, and uot from angle to angle. That is to say, it is with reference to a circle, a circumscribed octagon, and not an inscribed one. Take the number of quarter inches in the diameter and square them. Add to this square the square of the same diameter taken in inches. Divide the sum by 6. The quotient is the weight in pounds of oue lineal foot of the octagon steel bar. Example:

Octagon bar 1 inch in diameter.

$1 \times 4 = 4$ quarter inches.

$((4 \times 4) + (1 \times 1)) \div 6 = 16 + 1 = 17 \div 6 = 2.833$ pounds per liueal foot.

2 inches in diameter:

$((8 \times 8) + (2 \times 2)) \div 6 - (64 + 4) \div 6 = 68 \div 6 = 11.333$ pounds per lineal foot.

5 inches in diameter:

$((20 \times 20) + (5 \times 5)) \div 6 = (400 + 25) \div 6 = 425 \div 6 = 70.833$ pounds per lineal foot.

Comparing these results with your table, they will be found to agree exactly. Taking the number of quarter inches is, of course, the same thing as multiplying by 4, but given in that way it is easier to remember.

There are several approximate rules for finding the weight of wrought iron bars, and as some of your readers may not know them, and as they are easily remembered, and therefore useful, I will apend them. They give approximate results only, but they are sufficiently accurate to answer ordinary purposes.

Approximate rules for finding the weight of bar iron: For iron of rectangular or irregular section, take the area of the section in square inches and multiply by 10. The product is weight in pounds of 1 linear yard.

Example—Bar, 2×4 inches: $2 \times 4 = 8$; $8 \times 10 = 80$ pounds per linear yard; $80 \div 3 = 26.666$ pounds per foot.

For round iron bars, take the number of quarter inches in the diameter aud square them; divide the square thus found by 6. The quotieut is weight of 1 linear foot.

Example—Round bar 2 inches in diameter: $2 \times 4 = 8$; $8 \times 8 = 64$; $64 \div 6 = 10.666$ pounds per foot.

It was from this last rule that I deduced the rule for calculating the weight of octagon steel bars, and it is rather curious that while the latter gives only the approximate weight of round iron bars, it gives the exact weight of octogon steel bars, even to several decimal places.

There is another rule, easily remembered, that ap-

plies to railroad "T" rails, and which also gives exactly correct results. As is well known, railroad iron or steel is graded or classified by the weight per yard of a single rail. Thus what is known as "56-pound iron" (or steel) is that weighing fifty-six pounds to the linear yard. If it is desired to find the number of gross or long tons in a mile of track (single track, of two rails) it is easily found by the following:

Rule for finding the weight of railroad "T" iron in 1 mile of single track (two rails) in long tons: Divide the weight per yard by 7, multiply the quotient by 11, and the product is the weight of 1 mile of track in long tons of 2240 pounds.

Example—56-pound rails $(56 \div 7) \times 11 = 88$ long tons.

Example—85-pound rails $(85 \div 7) \times 11 = 133.57+$ long tons.

In the case of round iron or octagon steel, having a diameter of less than one inch, if expressed in quarter inches, it is only necessary to square the numerator of the fraction, as, for instance, for a diameter of three-fourths inch, square the 3, etc. If the diameter be expressed in eighths of an even number, it can of course be reduced to quarters, except in case of one eighth, where it is half a quarter—that is, .5—which is to be squared. If the number of eighths is uneven, it will be expressed by quarters and fractions, as in case of ⅞. Here there would be 3½ quarters, and the formula would be $((3.5 \times 3.5) + (.875 \times .875)) \div 6 = W$. A diameter of 1⅞ inches would reduce to 7½ quarter inches, and so on.

SANFORD ROBINSON.

Steeple Rock, New Mexico, Jan. 25.

The Precious Stones Industry.

In the annual report on the precious stones industry by G. F. Kunz is an interesting preliminary review of the industry for 1903 in which emphasis is laid on the future of California as a field for gem discoveries. Pala, in San Diego county, furnishes the remarkable new variety called kunzite, a lilac-colored spodumene. Crystals of great size and beauty have been obtained. It has been cut into gems for jewelry.

New discoveries and developments of fine rubellite and other tourmalines have also been made at Pala and likewise near Coahuila, in Riverside county. Topaz, both white and pale blue, have been identified for the first time in the State of California. It was found at Coahuila in crystals ¾ of an inch by 1 inch. Spessartite garnets were obtained near Ramona, in San Diego county. Chrysophrase was also extensively mined during the early part of the year in Tulare county. The massive green vesuvianite from Siskiyou county, which so resembles jade that it was first mistaken for that stone, has been further analyzed and examined and the name californite bestowed upon it. A second locality for it was found in Tulare county. The deposits of colored tourmaline at Mesa Grande were further developed during the year.

Outside of California, both prospecting and development work have been carried on in a few scattered districts. Turquoise has been mined at several places in New Mexico, Arizona, Nevada and in California, and many gems of great beauty have been obtained. The sapphire mines of Montana were worked by three different companies, two developing the fine blue gems at Yogo, in Fergus county, and the other the multi-colored or variegated stones at Rock creek in Granite county. Much of the material from all three localities, when not fine enough for gems, found a ready sale for watch jewels, principally among European manufacturers. The old beryl locality at Grafton, N. H., was reopened and some development was attempted. Very little was done with the tourmalines in Maine, although some prospecting took place at several localities in that State. In North Carolina, prospecting for beryl, amethyst and emerald matrix was continued.

In many of the ancient river channels of California, which are usually very much wider than the modern streams, the size of the material comprising the channel filling varies greatly, from fine gravel and sand to coarse cobbles and boulders, but in these channels at times are found boulders of quartz, quartzite or other hard metamorphic rock weighing 50 to 100 tons or more, while the greater part of the material filling the channel is small, few of the larger cobbles exceeding a foot in diameter, and not many of them. Near San Andreas, in Calaveras county, are numerous masses of greenstone with angular edges and rough surfaces, showing little signs of abrasion, though lying in a bed of gravel 60 feet in depth, and at 20 to 50 feet above bedrock, some of them on the surface. These boulders weigh from 50 to over 300 tons. The channels where they are found are narrow, less than 100 feet wide, and the surrounding rim rocks are not rugged. These occurrences indicate that the boulders were deposited in their present position by heavy floods, and that the superficial gravel was swept away quickly, as long continued scouring by moving detritus in the stream would have resulted in rounding the edges and faces of the boulders.

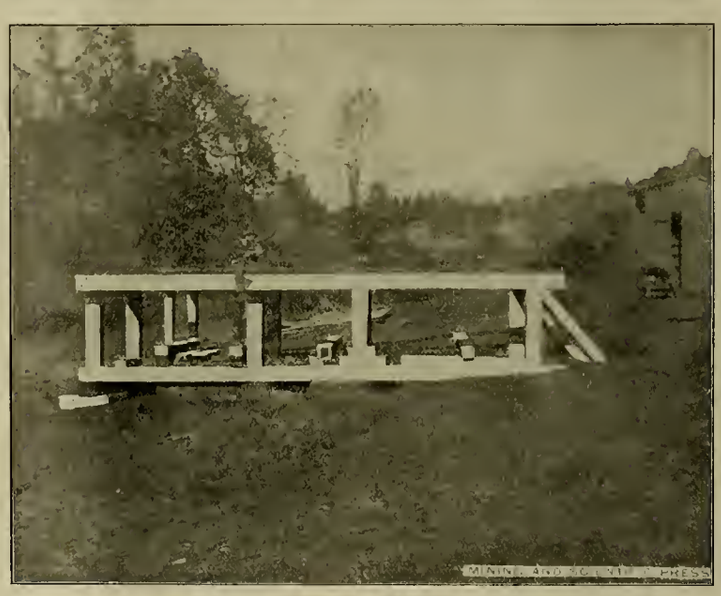
Simple Head Frame Construction.

Written for the MINING AND SCIENTIFIC PRESS

At many mines may be seen elaborate and expensive head frames, where the amount of rock handled or the depth at which the mine is being worked does not require or justify any such outlay or expense. The simplest frame adapted to either incline or vertical shafts is the two-post frame, with back angle braces. This type of frame is easily and cheaply constructed, requires the minimum of timbers, and it can be utilized with bucket, skip or cage. Skips may be dumped automatically into bins constructed in the frame, and cages may be operated as readily with this type of frame as any other, the guides being carried in front of the frame at a suitable distance, and buckets may be handled with a trip rope or even dumped automatically in this frame. It not infrequently occurs that a shaft is sunk in a flat where no dump can be obtained without resorting to artificial means. A crib may be carried up as the shaft is sunk by means of a windlass, and the material from the shaft filled in around it, and upon this insecure fill sills may be laid and the head frame built, but such a makeshift as this is only advisable where the work done is for the purpose of prospecting only and no permanent installment is contemplated.

The accompanying engraving shows a substantial frame constructed on a flat at the collar of a shaft. The conditions were undesirable, as the alluvial deposit overlying bedrock consisted wholly of loam and clay, situated in a wet, meadow-like valley. It was 13 feet to bedrock, but the vein was known to pass underneath the surface at the site of the shaft, the croppings being exposed in a creek not far distant. It was impossible to sink in the creek bed, and the shaft was located as shown. The shaft was begun and sunk to bedrock, the soft earth being carted away. Shallow pits were then dug at the surface to get down to the tough clay, and in these pits was laid a layer of broken rock to form a foundation for the heavy mudsills. There were four of these pits, located under the position occupied by the upright posts, shown in the engraving. On these sills were laid two long stringers, or sills, which were mortised to receive the tenons of the posts, the upper tenons of which were inserted in caps connecting the two posts of each set. Upon these caps were laid a second set of stringers which formed the real sills for the head frame. The shaft is situated near the forward end of the structure, the lagging showing beneath the lower sill. At the back short angle braces were placed to keep the frame from racking, and the whole was solidly bound with ¾-inch iron bolts.

The material from the shaft was dumped in and around this frame, and eventually it extended over half an acre of ground, the frame with its details of construction being buried from sight. Upon this substructure was erected a head frame 32 feet in height. It consisted of nine pieces of timber, viz., two posts, two back braces, one cap, two ties (one joining the angle braces and the other the posts under the cap) and two short upright posts between the lower tie and the cap to support the sheave wheel. The shaft was sunk to a depth of over 300 feet with this frame, the first 100 feet being vertical and the remainder inclined at a variable angle, following the vein, which had many changes of dip. The illustration on the front page is of a similar head frame constructed by the writer, who also built that above described. The conditions were not identical, though similar. In the latter case the forward end of the frame is supported upon a cap which rests upon two posts, these having their foot rest on a crib of timbers 3 feet square, the bedrock being too soft to support the post. The sills were laid on similar structures at four places along their length. The shaft was an incline, dipping at 50° beneath the engine house, it being impracticable to place the latter on the opposite side. The track in the shaft was projected upward at the same angle into the head frame. Self-dumping skips were used, these dumping automatically by allowing the forward wheels to run onto a horizontal track, until they were stopped by a bumper, the hind wheels being lifted off the track by the pull of the engine until the contents of the skip poured out. At 2½ feet above the collar of the shaft a gate was provided by cutting out a section of the track about 18 inches in length. This section was provided with hinges. If it was desired to hoist water, these were thrown back and the skip wheels ran out upon a flat section of track arranged there for the purpose, and the water poured out into a box and flowed away. The illustration shows the frame in process of construction. There are several temporary pieces shown, used for holding platforms, etc., which were subsequently removed. Owing to the length of the back braces, a counter-brace was put in to give the frame steadiness and to afford a support to the timbers carrying the track upward from the collar of the shaft. These timbers, 8x8 inches, rest on the cross tie midway of the auxiliary braces. All posts and sills were provided with mortises and tenons, and the ties were dovetailed in, as were also the vertical posts.



Sub-Structure for Head Frame, Built on Flat Ground.

One-inch iron bolts bound the sheave supports in place, between the cap and tie, carrying the sheave. The rock from the shaft was dumped in front of the frame until a sufficient space had been provided and the ground had settled sufficiently, when an ore bin was built, into which the skip dumped.

The short angle-braces under the cross ties connecting the main posts were inserted as precautionary, the spread between the posts being 10 feet, those under the lower tie particularly being necessary, owing to the shock incident to the striking of the skip wheels against the bumper, which would occur occasionally.

This type of head frame is recommended wherever it is possible to secure timbers sufficiently long, and even where they can not, splices may be made which will make a very strong frame. Shorter timbers usually cost less per foot than those of unusual length, which in some regions must be cut to order. In the case of the first frame above described, the material was ordered late in the fall, and one of the long timbers intended for angle braces failing to arrive at the mine, a brace was built of inch boards nailed together, the lengths being variable and the ends overlapping. This frame was subsequently taken down and removed to another mine, and every stick of timber was reused without change of any kind being necessary.

During the recent warlike demonstrations made by the Colombians, in South America, the American manager of the Darien Mining Co. and his staff at Cana closed the property and retired to Panama to await the result of developments. Doubtless this was a wise course to pursue, for while the United States Government would, no doubt, demand proper satisfaction of the Colombian Government for any damage to property of Americans, or for any indignity or injury inflicted upon Americans in Colombia, the miners showed their discretion in leaving a position so wholly unprotected as that at Cana.

Ordinary Transformer Connections.

Written for the MINING AND SCIENTIFIC PRESS by WM. H. KRITZER.

The common transformer consists of a laminated iron core for procuring a magnetic circuit upon which two coils of copper wire or flat ribbon are wound, the layers being separated from each other by some specially prepared insulating material. These coils are entirely distinct. The one called the primary is connected to the main circuits; the other coil, called the secondary, is connected to the circuit to which the current is delivered. When the current that is taken from the mains is sent through the primary coil it sets up a magnetism in the coil, which rapidly alternates with the changes of the current.

This changing magnetism sets up an alternating electro-motive force in the secondary, and this secondary current depends upon the number of turns of wire or ribbon in the secondary coil. If the secondary turns are less in number than the primary, the secondary electro-motive force will be less than the primary. The winding of the secondary is sometimes made for several different voltages, having its terminals arranged for either series or multiple connections; others are movable in order to obtain a practically constant current.

One of the necessary requiremeuts of a good transformer is that it will withstand undue heating, which in the high voltages may be dissipated by artificial or simple radiation from the surface of the containing case, by air blast, or by the circulation of water through pipes immersed in oil, or by the constant removal of heated oil and its return after having been cooled. A transformer never gives out quite as much power from the secondary as it takes in from the primary mains, because there are losses of two kinds: first, the iron loss due to the magnetic reversals in iron; second, copper loss, resulting from the passage of current through the conductors. Experience and test have made it evident that the installation of one large transformer instead of several small ones is very much more economical in first cost, regulation and running expeuses.

Ordinary transformers, having parallel connections and built for the same potential and frequency, may be connected together in a variety of ways that need no explanation outside of the accompanying diagrams.

Where continuity of service is very important in the three-phase system, the "delta" connections are of great advantage, as the removal of one transformer does not interrupt the distribution, and the removal of two trausformers still admits of power transmission on a single phase or circuit. The advantage of the "star" connection over the "delta" is that for the same transmission voltage smaller transformers can be installed.

Transformers used for raising the voltage are known as step-up transformers; those used for lowering the pressure are known as step-down transformers.

When transformers are identical as to make and type it will generally be found that the secondary ends can be connected exactly like the primaries—i. e., if the two right hand primaries are connected together, then the two right hand secondaries will usually go together. However, if manufactured by

different makers it is necessary to test them in order to avoid the possibility of connecting them in such a way as to short circuit the one on the other, for if they are to be run in parallel the windings must have the same polarity at a given instant, and although it is not imperative that they be of the same type it is decidedly preferable.

This polarity cannot be determined by any ordinary method, but it is possible to find out whether or not transformers agree in this respect by connecting

the two to the primary circuit (see Fig. 1), then connect one secondary terminal of one transformer with one of the other transformers by means of a small fuse wire E; touch the remaining secondaries together. If the fuse melts the connections are wrong, and in making them permanent C must connect with A and D with B. If the fuse does not melt, the connections—C to D and A to B—may be made permanent.

The Geology and Copper Deposits of Bisbee, Arizona.*

Written by F. L. RANSOME.

The following paper aims to present in condensed form the salient results of a detailed geological study of the Bisbee quadrangle, Arizona, carried on during the latter part of the year 1902. It is essentially an abstract of the final official report which will shortly appear in the series of professional papers of the United States Geological Survey, accompanied by maps, sections and illustrations.

I. GEOGRAPHY.—The Bisbee quadrangle, which includes the Warren mining district, lies in Cochise county, in the southeastern part of Arizona, adjoining the Mexican boundary line. The area of the quadrangle is about 170 square miles, and includes the southeastern half of the Mule mountains, one of the smaller of the isolated ranges characteristic of this part of Arizona. The Mule mountains, while less markedly linear than the Dragoon, Huachuca, Chiricahua and other neighboring ranges, have a N. W.—S. E. trend. They may be considered as extending from the town of Tombstone to the Mexican border, a distance of about 30 miles. On the northwest they are separated by the broad, flat floor of Sulphur Spring valley from the Chiricahua range, and on the southeast by the similar broad valley of the Rio San Pedro from the Huachuca range. The maximum width of the range is about 12 miles, and its greatest elevation attained by Mount Ballard, west of Bisbee, is 7400 feet above sea level.

The town of Bisbee, with an estimated population of 6000, is crowded into a few narrow confluent ravines near the heart of the range, 7.5 miles north of the international boundary. It is connected by the El Paso & Southwestern Railroad to the east with the new town of Douglas in Sulphur Spring valley, with Deming and El Paso. To the west, branches of the same road run to Naco on the Mexican boundary, to Tombstone and to Benson on the main line of the Southern Pacific Railroad. At Douglas, connection is made with the Nacosari Railroad to Cos, and at Naco with the Cananea, Yaqui river and Pacific Railroad to Cananea, thus bringing the new smelters at Douglas within reach of the important mines at Nacosari and Cananea in the State of Sonora, Mexico.

II. GENERAL GEOLOGY.—The first attempt to describe the geological environment of the Bisbee copper ores was that of Wendt, in 1887, followed thirteen years later by the more comprehensive account by Douglas. Both these papers, however, touch but briefly on the geology and structure of the Mule mountains, being concerned mainly with the ore bodies and the metallurgy of the ores. Dumble's reconnaissance notes published in 1902, although necessarily fragmentary, are really the first step toward any general knowledge of the broader geological features, and to him is due the first recorded recognition of the extensive Cretaceous deposits of the Bisbee region.

The rocks of the Mule mountains may be primarily divided into five main groups: (1) a pre-Cambrian basement of crystalline schists; (2) a Paleozoic sedimentary series; (3) a Mesozoic sedimentary series; (4) Quaternary valley deposits; and (5) intrusive igneous rocks.

One, standing upon Mount Ballard, can look out over the clustered ridges and peaks composing the mountain range and to a certain extent trace the general distribution of the rocks by the character of the topography. The Quaternary deposits floor the broad valley plains stretching away from the intricately embayed line marking the foot of the mountains. The N. W.—S. E. diagonal of the Bisbee quadrangle, a line which passes very near the town of Bisbee, and corresponds with the course of Tombstone canyon, roughly divides the mountainous part of the quadrangle in two topographical divisions. Northeast of this line the mountains are sculptured from comparatively soft Mesozoic beds, striking approximately with the trend of the range (N. W.—S. E.) and dipping at generally moderate angles toward Sulphur Spring valley on the northeast. The slopes of these hills are comparatively smooth, although the occurrence of hard fossiliferous limestone in the middle of the generally arenaceous group has occasioned a persistent cliff of erosion, conspicuous from points near Bisbee. Southwest of this line, pre-Cambrian schists and Paleozoic beds, both cut by eruptive rocks, prevail. These are more resistant of erosion and more heterogeneous in character than the Mesozoic beds and have a far more complicated structure. Their degradation has consequently resulted in a more rugged and less regular topography.

THE PRE-CAMBRIAN BASEMENT.—The rocks forming the pre-Cambrian basement, the oldest rocks known in the Mule mountains, are fine-grained sericite schists, derived from the ancient sediments. These, which have been called the Pinal schists, were probably original shales or arkose sandstones, which were folded and metamorphosed into their present crystalline condition before Cambrian time.

THE PALEOZOIC SEDIMENTARY SERIES.—After long erosion the Pinal schists were reduced to a surface of very slight relief, which in Cambrian time was submerged beneath the sea and covered with the sands that are now represented by the Bolsa quartzite (Cambrian), from 400 to 500 feet in thickness. The Bolsa quartzite has at its base a thin conglomerate, which rests with unconformity upon the eroded edges of the Pinal schists.

The submergence of the area continued, and about 750 feet of thin-bedded, cherty, fossiliferous Middle Cambrian limestones, named the Abrigo limestone, accumulated on top of the Bolsa quartzite. No record of Silurian time has been discovered in the Bisbee quadrangle. Overlying the Abrigo limestone, apparently in perfect conformity, are 340 feet of dark-colored, compact, rather thin-bedded limestones, with some intercalated shales, all carrying an abundant and characteristic Devonian fauna, consisting chiefly of brachiopods and corals. This formation is distinguished as the Martin limestone.

The opening of Carboniferous time was, in this region, unmarked by any interruption of the continued subsidence. No unconformity has been detected between the Devonian and the lower Carboniferous (Mississippian) rocks. The latter consist of white or light-gray granular limestones, often made up almost entirely of crinoid stems. The thickness of the lower Carboniferous limestone may be provisionally given as 700 feet. The beds are often 6 feet or more in thickness, and commonly form cliffs overlooking slopes carved from the less resistant Devonian and Cambrian limestones. This formation has received the name of the Escabrosa limestone.

There is in the Mule mountains no discoverable stratigraphic break between the lower and upper Carboniferous beds. Subsidence apparently continued, and the generally thinner beds of upper Carboniferous (Pennsylvanian) limestone accumulated to a thickness of over 3000 feet above the lower Carboniferous. The upper Carboniferous limestones are usually more compact in texture than those of the lower Carboniferous, and are more fossiliferous. They are also somewhat more variable in color, pinkish and yellowish beds being of frequent occurrence. This formation has been named the Naco limestone.

The local Paleozoic section from the Pinal schists very nearly to the top of the Escabrosa limestone is well exposed on the northeast face of Escabrosa ridge, about 1.5 miles west of Bisbee. The beds of the Naco limestone are best seen in the hills just north of Naco Junction (5 miles southwest of Bisbee), and the conformable relation between the Escabrosa and Naco limestones is well shown near the Whitetail mine, about 2 miles due south of Bisbee.

(TO BE CONTINUED.)

* Abstract Trans. Amer. Inst. Min. Eng.

Annual Report of the Director of the Geological Survey.

The twenty-fourth annual report of the Director of the United States Geological Survey, now ready for distribution, shows that the several branches of that organization greatly enlarged the scope of their work and increased their activities during the last fiscal year. The period covered is from July 1, 1902, to July 1, 1903, for the work of which Congress had appropriated the sum of $1,337,470.

The survey as now organized is divided into five branches—the geologic, topographic, hydrographic, publication and administrative.

The geological branch includes the divisions of geology and paleontology, of mining and mineral resources, and of physics and chemistry. The administration of the division of geology and paleontology was in the hands of the geologist in charge of geology, while scientific supervision rested with the chiefs of sections. The various sections included those of areal geology, Pleistocene geology, pre-Cambrian and metamorphic geology, petrology, economic geology of metalliferous, economic geology of non-metalliferous minerals and paleontology. A new section was created during the year—that of petrology.

A new feature of the work of the division of geology and paleontology was the preparation and publication of a bulletin entitled, "Contributions to Economic Geology, 1902," which is intended to be the first of an annual series.

In Alaska five parties were engaged in field work during the summer of 1902. An account of the investigations made is given in the report.

The year's work of the division of topography may be summarized as follows: Two base lines were measured; primary azimuth observations were made at four triangulation stations; 395 triangulation stations were occupied or located; 1487 miles of primary traverse were run; 36,275 square miles were covered by detailed topographic mapping, this area being distributed through thirty-six States and Territories; 29,160 miles of levels were run; and 1826 bench marks were established, and at each of these an iron post, a bronze or aluminum tablet, or a copper or aluminum plug was set in place. In connection with the Alaskan surveys, about 20,080 square miles were mapped topographically. About 45 miles of the boundary of the Bighorn Forest Reserve of Wyoming were surveyed and marked with special iron posts, this work completing the survey of the reserve; also 154 miles of the boundaries of the Black Mesa Forest

Reserve and 12 miles of those of the Mount Graham Forest Reserve of Arizona were surveyed and similarly marked. In the office ninety-seven atlas sheets were completed and the entire revision and redrafting of the large topographic wall map of the United States was commenced.

About 7500 square miles of forest reserves were examined during the season. The appropriation for this work amounted to $130,000.

This report is published for gratuitous distribution and may be procured on application to the Director of the Geological Survey, Washington, D. C.

Compressed Air Power Plant at the St. Louis Exposition.

The central compressed air power plant at the St. Louis Exposition will contain two main compressing units; one cross-compound two-stage Cincinnati-gear compressor, having 13 and 24-inch steam cylinders, 22 and 14-inch air cylinders and 24-inch stroke, with a displacement at 125 R. P. M. of 1300 cubic feet per minute, and one cross-compound two-stage Meyer-gear compressor having 12 and 20-inch steam cylinders, 18 and 11-inch air cylinders and 18-inch stroke, with a displacement at 100 R. P. M. of 530 cubic feet per minute. The first machine is to supply the general compressed air requirements of the Exposition, the second is to supply the transportation exhibits. The larger machine is stated to be the first compressor of its type thus publicly exhibited.

The general construction of one of these machines is shown in Figures 1 and 2. The frames are of massive construction, with a long bearing on the foundation; the steam and air cylinders, joined in the direct line of thrust by heavy cast-iron housings, are also supported by bed plates under their entire length.

The steam valve gear is of the four-valve type. Steam distribution is effected by means of short double-ported slide valves, working at either end of the steam chest on a valve face as close as possible to the cylinder bore, the port volume being restricted as far as the large valve area will allow. The exhaust valves are of the Corliss rotary type and are placed at the bottom of the cylinder. This construction has been followed in order to produce a valve gear having the essential advantages of a Corliss, namely separate passages for the steam and the exhaust with corresponding reduction in cylinder condensation, together with short, straight ports and small clearance.

The air valve gear is, however, the distinguishing feature of this machine, designed to combine positive action, noiseless operation and durability of the mechanically moved valve with the elasticity of the poppet valve. Noise or rapid wear of the poppet valve, due to the impact of the valves closing at the reversal of stroke, is stated to be eliminated by mechanically closing the passages underneath the poppet valve, and leaving a cushion of air upon which the latter seats.

These machines are built by the Laidlaw-Dunn-Gordon Co., Cincinnati, O.

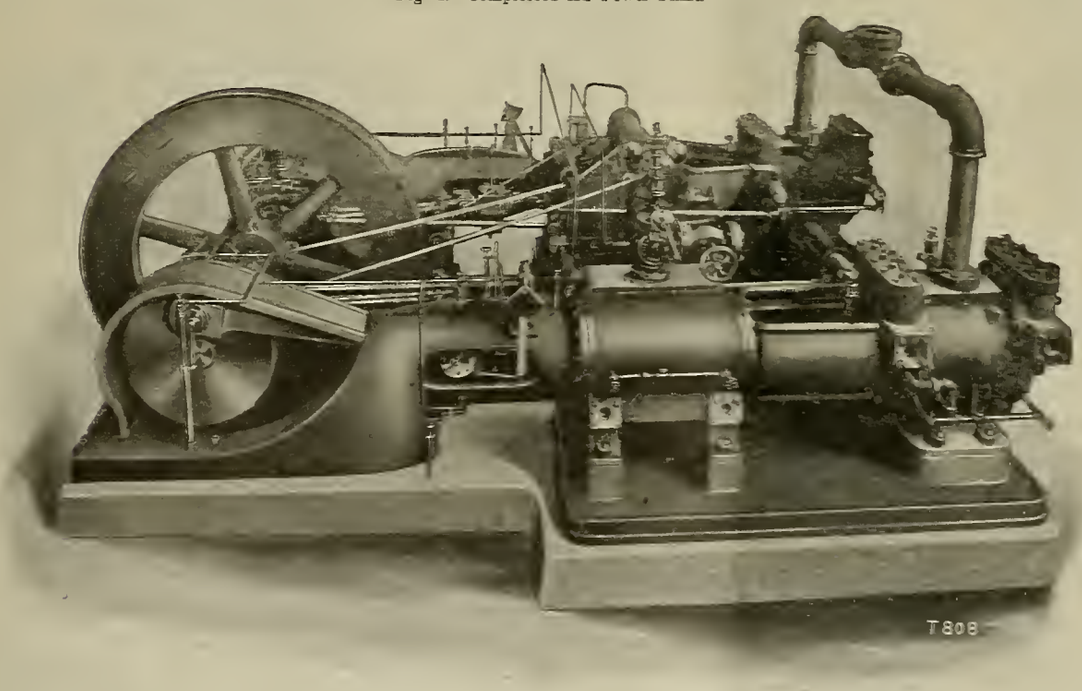

Fig. 2.—Compressed Air Power Plant.

Contact-Metamorphic Deposits in the Sierra Nevada Mountains.*

Written by H. W. Turner.

In the Dardanelles quadrangle of the map of the United States Geological Survey, 3 miles northwest of Tower peak, there is a considerable mass of quartzite, marble and dark, fine-grained gneiss. At the edge of the coarsely crystalline white marble, having a width of about 400 feet, is a white schistose rock, which under the microscope shows pyroxene. Granitoid rocks and quartz veins cut both the marble and the pyroxene schist. The granitoid rock is a fresh quartz-diorite, containing primary augite and titanite. One of the quartz veins at the contact of the marble and pyroxenic schist has been prospected, and much green epidote, garnet, blende and some molybdenite have been found in it.

In the Yosemite quadrangle, east of Iron creek and on the eastern slope of the mountain, at an altitude of 9215 feet, there are numerous streaks and bunches of garnet-pyroxene-epidote rocks, in which open cuts have been made that in some cases show sulphides, notably blende. From one cut issues a sulphurous gas that is doubtless forming from the oxidation of sulphides. Adjoining the schists containing these contact-metamorphic deposits are metamorphic lavas, probably meta-andesites, containing streaks and bunches of magnetite.

In the Yosemite quadrangle, on the southeastern slope of Mt. Hoffmann, several cuts exposing sulphides have been made in a schist lense enclosed in a granitic rock. A shaft also has been sunk on a lode composed of garnet, epidote, quartz, calcite and a little galena and molybdenite. The lode is at the granitic contact. Not far distant, but not directly connected with this lode, is a mass of marble.

In the Mt. Lyell quadrangle there are two series of schistose rocks, one composed chiefly of quartzite and slate, which I have called the Tioga formation, and the other, composed chiefly of metamorphic volcanic rocks, which I have called the Dana formation. Most of the metamorphic volcanic rocks of this district, including both lavas and tuffs, are now schists. Iron mountain is largely made up of these volcanic schists, containing veins of magnetite, which have been exploited to some extent. The property is now owned by the Minarets Mining Co. The magnetite ore shows traces of copper carbonate, but the original copper mineral has not been determined. The magnetite is associated with a green, massive, fibrous hornblende, which contains prisms 2 or more inches in length of a light-colored mineral, possibly apatite. An analysis of the ore shows from 0.243% to 0.454% phosphorus, but no titanic acid. Although the magnetite veins are not at the immediate contact of the neighboring granitic rocks, they should, perhaps, be classed with contact-metamorphic deposits.

In the foothills of Madera county, Cal., there is a belt of contact-metamorphic schists (chiefly mica and chiastolite schists), containing copper deposits at several places. Two of these deposits, the Ne Plus Ultra, belonging to the California Copper Co., and the Buchanan, were examined. The ore of the Ne Plus Ultra mine is chalcopyrite in a gangue composed largely of a colorless hornblende, resembling tremolite. There are also at this place many dikes of diorite-porphyry. In the clay schist country rock there are numerous crystals of chiastolite, often 2 inches in length. These chiastolite schists belong to the Mariposa formations. Granitic rocks occur not far distant toward the east. At the Buchanan mine the enclosing schists contain garnet. The ore is chalcopyrite, associated with a chlorite (resembling delessite), colorless amphibole, pyrite, pyrrhotite, garnet, quartz and reddish brown biotite. Granitic rocks are near by.

*Trans. Am. Inst. Min. Eng.

SOME smelters contend that coke is essential in the blast furnace to keep the charge from packing.

Underground Handling and Transport of Ore.*

NUMBER II.—CONCLUDED.

Written by CHARLES H. SAXER and GEORGE CARTER.

A modification of the wire rope tramway, generally known as an aerial gear, is likewise being used, and, under certain conditions, has proved very effective. It consists of two standing wire ropes forming the track; these are firmly fixed at one end and attached to tightening rigging screws at the other, the wire ropes being passed through the eyebolts and securely held by clamps, these standing ropes throughout their length being supported at intervals on brackets fixed on light drill bars or hangers from the roof of the stope. The buckets, holding from 3 to 5 cwts., are fixed to bridles attached to a frame running on wheels on the carrying rope track.

These are worked by a ¼-inch or ⅜-inch traction rope attached to the top end of each bucket, and in order to adjust for the varying positions of the accumulated broken ground in the stope, are wound round two separate drums, 6 to 12 inches in diameter and about 12 inches wide, fitted with band brakes. These drums, keyed to a common axle, are fixed on an ordinary rock drill bar, the weight of the full bucket descending raising the other automatically; but, in cases where the inclination will not allow of this, a handle may be fixed to the drums and manual labor used.

In the case shown in Figs. 4 and 5, which is working at the Nourse Deep, Ltd., twenty-five 3-cwt. cars were run down a length of 150 feet in half an hour. Four "boys" are employed shoveling into and running the gear per shift, whereas previously nine "boys" shoveled the same quantity of rock over half the distance.

From these various contrivances the broken ore is deposited into boxes, platforms, trucks, etc., or into ore passes, as may be most suitable for trucking in the levels.

Fig. 4.—Aerial Tram Bottom, Nourse Deep, Rand, S. A.

Fig. 5.—Aerial Gear Top, Nourse Deep, Rand, S. A.

Broken rock from development faces has to be cleared as soon as possible after blasting, if rapid headway is to be expected, ground from drives being shoveled into trucks; that from winzes, where vertical, an ordinary hand windlass and kibble, balanced or otherwise, is used. In steeply inclined winzes the kibble slides on rail guides. Where the inclination is not great (see Fig. 6) a track is laid of light rails and a small, self-dumping skip is used, usually worked by an air winch or hand windlass, provision being made at the mouth of the winze for tipping into a truck.

In raises where not sufficiently steep for the broken ground to gravitate to the level below, shoveling by "boys" is usually done; in such cases, a shaking chute, as previously mentioned, might be used with considerable advantage. Another method, although it has not yet been sufficiently tested to have been proved economically successful, is worthy of consideration and is being experimented with on the Nourse Deep, Ltd. In this a jet of water under pressure is utilized for washing the broken ground down a stope; this is especially applicable to the final cleaning down of the rich "fines" before abandoning the worked out stope, in place of the laborious method of sweeping down with brooms at present in use. Furthermore, this method may well serve its purpose in bringing to light the rich "foot wall leader" often left in South Reef stopes, as well as allaying the dust, in which it would be of especial advantage in washing down, in flat raises, the broken ore to the level below after blasting.

TRANSPORT OF ORE TO SHAFT LOADING STATIONS.—In extensively worked mines it is also necessary that labor-saving appliances be adopted in this connection, if large outputs at a minimum cost are to be maintained. Conditions vary so much in each mine that no hard and fast rule can be laid down as regards the methods to be adopted.

Where mechanical appliances are to be used, it is advisable that main drives should be driven as straight as possible, of large section, suitable for not less than two tracks, and generally in the footwall side, keeping the reef just in the "banging" on that side, so that boxes can be set at a sufficiently steep inclination for the rapid filling of trucks. On the floor of the level rail tracks are laid weighing from twelve to twenty-four pounds. These are laid on iron sleepers and stayed at intervals with wooden binding sleepers cut the width of the drive and hitched into the sides.

The usual type of trucks used are U-shaped steel side tipping, and flat-bottom end tipping, having a capacity of from 10 to 16 cwts., these having been found the most suitable for handling. The wheels are generally fast, revolving with the axles; but in cases where there are sharp curves, especially at shaft stations, fast and loose wheels on opposite sides are advantageous. The bearings are generally lubricated with grease by hand, and there is room here for the adoption of a good form of automatic or continuous lubricator.

For the transportation of the trucks to and from the loading stations at the shaft, various systems are in use, hand labor being almost exclusively used in the mines here at the present day, and is carried out by white men, Cape boys and natives.

Animal haulage is being used only to a very small extent, and likewise mechanical; but with this latter method there is room for a considerable extension of its application, and especially if a large number of rock drills are concentrated in the stopes on one level, thus insuring a large quantity of broken ore being handled continuously.

In this connection, we believe that one of the first adaptations of a main and tail haulage system on the Rand in metalliferous mines was installed in the Nourse Deep, Ltd., and this arose from the fact that the shaft in the western section of this mine was not equipped for handling large quantities of ore, thus necessitating its transport to the central shaft.

This haulage first consisted of one air winch having two drums, one loose on the shaft, and each equipped with clutch and brake, the tail rope being carried overhead and guided around pulleys. To obviate the excessive wear and tear, this method has since been improved on by using two air winches, one at either end of the haulage, the larger one, of 7-inch diameter and 12-inch stroke, single cylinder, hauling the full trucks with a main rope of ⅞-inch diameter, while from the opposite end of the smaller winch of 5-inch diameter and 8-inch stroke, double cylinder, hauls back the empties with a rope of ½-inch diameter.

The trains consist generally of eight 16 cubic foot trucks. The level through which this haulage has to work is most unfavorable, having a number of sharp curves, as will be seen from the diagram; it is 1300 feet in length and has only sufficient room for a single track for the greater part of this distance, and, under the conditions which exist, its efficiency over hand tramming has been proved, as the cost over

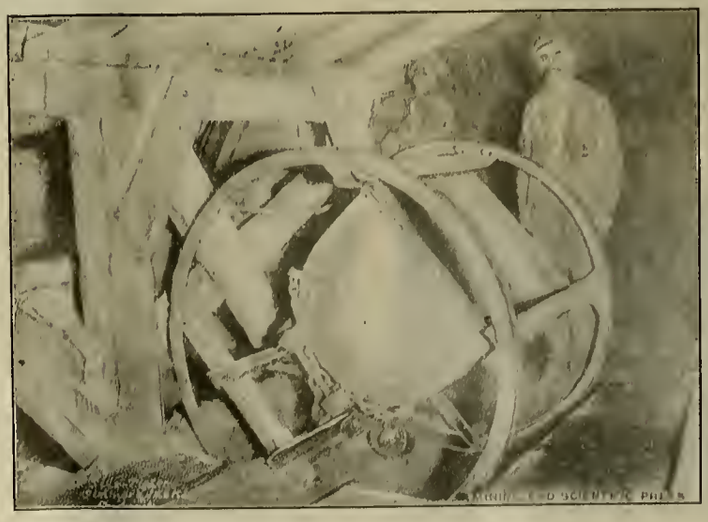

Fig. 6.—Side Tipler, Simmer and Jack Mines, Rand, S. A.

*Trans. Chem., Met. and Min. Soc., S. A.

this length works out an average of 8d per ton, inclusive of maintenance.

One "boy" drives the winches at either end and a white man travels with the trains and has complete control, by means of electric bell signals, anywhere along its length. This practically means that, as far as labor is concerned, it requires only one man and two boys to carry out this tramming.

On reaching the hooking-off point the trucks are detached singly and run by means of a sharp downgrade to a set of points, from which they continue on a short up-grade, sufficient to keep them automatically opposite the bin.

When the ore is dumped, which may be done by a tipler (see Fig. 6), and the truck righted, it is allowed to run back across the points to the hooking-on point on the return empty track.

At either end the drive is widened to allow of this double track being laid for a sufficient distance. Owing to the sharp curves, the rope has to cross the track at various points, and at these points hardwood rubbing blocks or rollers are suitably placed to prevent contact with rails. The rope is also guided around the curves by rollers set vertically. These are about 12 inches long and 9 inches in diameter, being made of circular wood blocks inclosed in a steel pipe, having bearing pins on either end working, preferably, in hard wood journals kept well greased.

The life of the rope is a comparatively short one, being largely influenced by the acidity of the mine water and the bending strains to which it is subjected in this particular case.

A similar haulage is being installed in one of the lower levels of this mine, and, as will be seen from the

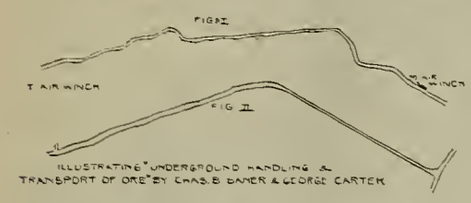

diagram (see diagram), the working conditions will be much more favorable.

This drive, as originally driven, was comparatively straight, and has been further straightened by stripping the sides to a sufficient width to allow of two tracks being laid where necessary.

The length of this haulage will be 1160 feet, and power will be supplied in a similar manner to that previously described.

This system up to the present seems to be the most suitable for local conditions, and can be utilized either where a level has been driven its entire length, when stationary air winches can be fixed at shafts and extreme points east and west, or where the level is still being driven and tramming from stopes at various points has to be carried on simultaneously; the air winch, operating the tail rope, can be mounted on a traveling hogie, which can be moved to and temporarily anchored at any desired point.

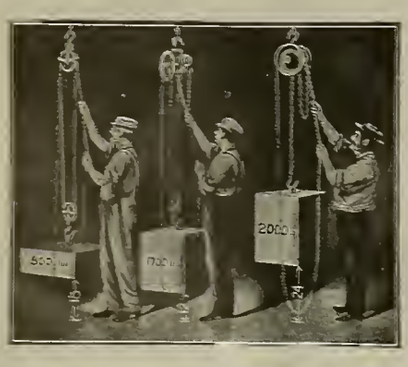
Main levels, where possible, should be laid out with a suitable grade in favor of the full trucks.

Other devices, although not at present in use, might be proved to be suitable, such as self-acting incline planes, endless rope haulages, electric motors, compressed air motors, etc., or even a belt conveyor.

Some of these, although often utilized in colliery practice, have, so far as we know, up to the present, not been extensively used in metalliferous mining, but might receive greater attention in the near future than they have done hitherto.

Labor Saving in Lifting.

Herewith is illustrated the weight and height a



man can lift in half a minute with two blocks such as furnished by the Yale & Towne Manufacturing Co., 9–11–13 Murray street, New York.

Regarding these labor saving devices the Yale & Towne Co. say: With the differential three men can easily lift a ton a foot "by pulling 216 pounds and overhauling 30 feet of chain; with the duplex one man does it by pulling only 87 pounds, but overhauling 59 feet of hand chain; while with the triplex one man pulls 82 pounds and handles only 31 feet of chain. You can prove this at our expense if you wish. Write us for a triplex block for trial use."

The Manufacture of Gun Cotton and Nitroglycerine.*

NUMBER III—CONCLUDED.

Written by BRYANT S. DRAKE.

Life could hardly be supported in the midst of the fumes, yet as soon as the charges are all run down, four men, each with a handkerchief over his nose and mouth, and a rubber squeegee, shaped to fit the trough, in his hand, chase down the portions of the charge remaining in the troughs. The fumes thin out very quickly—in four or five minutes one can see the entire distance of 600 feet. The charge runs from the troughs directly to the separating tanks, and is allowed to stand while the nitroglycerine rises and the surplus acids sink, till a distinct dividing line can be seen. The nitroglycerine is then drained off to the washing tubs by means of a submerged funnel, and washed with water, sodium carbonate, salt water and fresh water in succession. In washing, the nitroglycerine changes from a dark oily liquid to a turbid, whitish one, and once separated from all free acid, loses its greatest inflammability and becomes comparatively safe. So the washings are continued until the nitroglycerine is neutral to test paper.

The next step is to run it upon the filters. These are simply large cloths, similar to the familiar gunny sacking. The waste acids, as separated from the nitroglycerine, are run to a second separating house, and the remaining nitroglycerine is removed. The acids are then separated by heat, and the H_2SO_4 is reconcentrated by evaporation, but the HNO_3 is not capable of being strengthened in this way, and is practically of no value.

The nitroglycerine is tested by heat for its stability and its ignition point, and the amount of free acids in it is determined. The percentage of nitrogen is also determined by the nitrometer the same as for gun cotton.

Nitroglycerine is not used in the free state, as it is too violently explosive. The chief factor in the development of the industry was the discovery that its explosive violence and its stability could be regulated by mixing it with some absorbent. The product thus obtained is a dynamite. Naturally there are several classes:

(a) An explosive mixture:
  1. Nitrate class (Judson powder).
  2. Chlorate class (Vigorite powder).

(b) An explosive compound:
  1. Nitro substitution compound (Castellanos powder).
  2. Nitro derivative compound (Explosive gelatine.

All dynamites, of whatever class, are manufactured by similar processes. There are three main operations:

1. Mixing the base.
2. Incorporating the nitroglycerine.
3. Packing the cartridges.

Each operation is done in a separate building, and each building is surrounded by bulkheads similar to those around the nitroglycerine mixing house. These bulkheads are from 15 feet to 20 feet high and from 4 feet to 8 feet thick at the base, and are made of two concentric rows of heavy timbers, filled in between with solid earth. The dry mixing is done in an iron tub by means of brass stirrers actuated by an electric motor. Into this tub the ingredients are dumped in a pulverized state, and, when thoroughly mixed, the charge is taken to the wet mixer, weighed and placed in wooden vats. The nitroglycerine is then poured from wooden buckets, and thoroughly incorporated by means of wooden spades in the hands of Chinese laborers.

The finished dynamite has the appearance of brown sugar or moist pine sawdust. It is filled into cartridges and boxed ready for shipment. The papers of which the cartridges are made are rolled and pasted by girls, the only female operatives connected with the plant. A skillful girl can roll as high as 300 cartridges an hour, but such a pace is not long kept up save for the making of a record. The pasted paper cylinders, closed at one end, are dipped in melted paraffine, allowed to drain and dry, and then carried to the packing houses by Chinese coolies. The filling of the cartridges is done by a packing machine. These machines fill from fifteen to twenty cartridges at a time, the dynamite being rammed in by a wooden plunger. The top of the cartridge is then creased and folded over, and the cartridges are packed in boxes.

The Chinese are a bit superstitious, and when electric lights were installed to enable working later on short and dark days, they refused to work when the lights were burning, and the experiment came to naught. The operation of packing is very dangerous, and white men will not stick to their jobs long enough to become expert and make it less dangerous, and so the Chinese superstition has to be tolerated.

The finished and boxed cartridges are stored in magazines awaiting shipment. All transportation is carried on by a narrow-gauge railroad, operated by compressed air locomotives. These little trains carry the boxes to the loading switches of the Santa Fe and Southern Pacific railroads, so that steam locomotives do not run into the works to points where stray sparks might do damage. Fire is always to be feared in the works, and the burning of grass in fields near by is anxiously watched, and the foreman will, on slight provocation, send all the available men in the yards to extinguish it before it gets anywhere near the grounds.

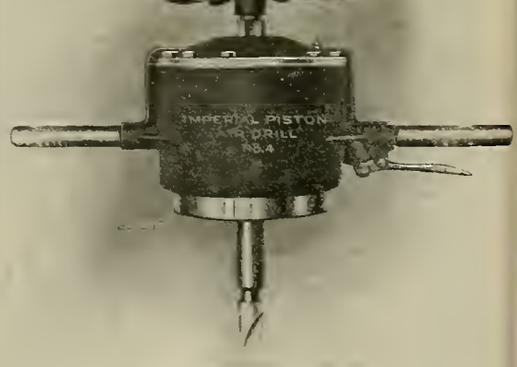
The condition of the workmen at the plant is as good as can be expected, considering that the men do hard labor and have dangerous occupations. Workmen on the outside, as those who handle the supplies, build track and perform similar day labor are called, receive $2 per day, and can get half a day off at any time by applying to the foreman. Regular promotion of faithful employes is the company's rule, the rise being from outside labor to the acid, gun cotton and nitroglycerine works in succession. The scale of wages rises in successive departments. An experienced employe, who does his work faithfully, is rarely discharged, and is sure of promotion if he abstains from drunkenness. The men in the gun cotton works, and especially those who do the dipping of the cotton, are constantly exposed to the fumes of the mixed acids, and this is the most undesirable position in the works. The acids affect the teeth and lungs. Good teeth will be decayed in six or eight months. Fatalities occasionally occur from breathing the acid fumes. When a man is disabled here he is placed in an easier position; in event of illness, he is treated at the company's expense, and is sure of a job when he is again able to work. The families of fatally injured employes are pensioned, and able-bodied children may obtain employment without fear of discharge, even though their services are of little value to the company. The nitroglycerine works are the most dangerous, and no married man will be employed there. Those who desire to live in the quarters furnished by the company may do so, and they are provided with comfortable rooms, bedding, water and light. The rooms are taken care of by a Chinese servant. The company also operates a boarding-house, where meals are furnished at 25 cents each or $15 per month. Emergency supplies are kept on hand to treat injured employes before they are taken to the hospital, and medicines are furnished for the general indisposition of the employes, from biliousness to ingrowing toenails, but no remedy is provided for laziness. The natural alkali of the surrounding region, together with the waste from the plant, makes the available water fit only for fire protection, and the drinking water is shipped in in iron tanks and stored for use at convenient points about the works.

The power plant which furnishes electricity, compressed air and water for fire protection is operated by steam engines driven by oil-burning boilers. The fire protection is unique in its way. Near each building are one or more nozzles connected with the mains and mounted on vertical pipes in such a way as to be capable of being pointed in any direction. The object of this is that one may train a stream of water upon a fire, clamp the nozzle and then retreat before an explosion occurs. All the buildings are connected by telephone, and a "central" is provided for all switches and connections.

*Abstract California Journal of Technology.

Piston Air Drill.

Herewith is illustrated the Imperial piston air



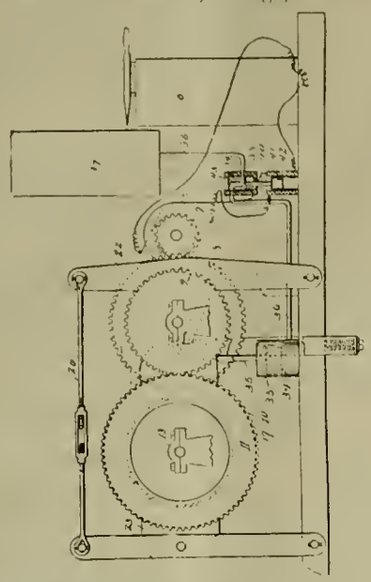
drill No. 4, adapted to drilling up to 3 inches, reaming and tapping up to 2½ inches, and rolling flues up to 4 inches diameter; air consumed per minute, 35 cubic feet; weight 57 pounds. This is one of a line of pneumatic tools made and furnished by the Rand Drill Co., 128 Broadway, New York.

Mining and Metallurgical Patents.

PATENTS ISSUED JANUARY 26, 1904.

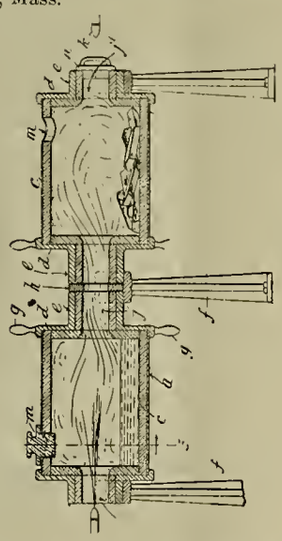
Specially Reported and Illustrated for the MINING AND SCIENTIFIC PRESS.

BRAKE FOR HOISTING MACHINES.—No. 750,283, F. K. Hoover and A. J. Mason, Chicago, Ill.



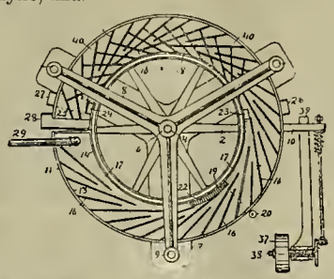
In hoisting apparatus, combination with brake pulley, of brake shoe applied to periphery thereof, back strut supporting brake shoe against pulley and constituting one link of toggle whereof other link is constituted by sector of brake pulley between axis and brake shoe, means connected to brake shoe normally tending to draw same in direction to spread links of toggle, and means for counteracting brake shoe actuating means during hoisting of load.

MELTING FURNACE.—No. 750,748; J. F. Barker, Springfield, Mass.



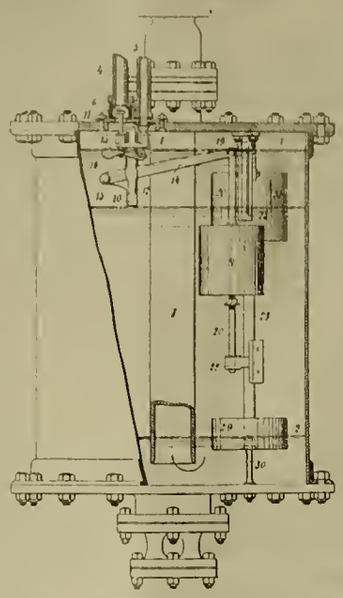
Combination in melting furnace, of two separate chambers to receive charges of material, chambers being independently revoluble on common axis, there being passage from one chamber to the other; with means to introduce gaseous or liquid fuel into either of chambers.

ORE CONCENTRATOR.—No. 750,281; T. H. Hicks, Fort Wayne, Ind.



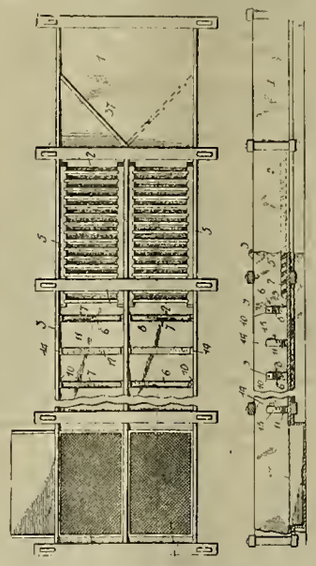
In ore concentrator, spirally descending concentrating trough, series of riffles 16 arranged diagonally upon bottom of trough and converging toward inner wall thereof; and means to differentially oscillate trough.

PNEUMATIC FLUID ELEVATOR OR PUMP.—No. 750,326; A. Montenegro y Van Halen, Madrid, Spain.



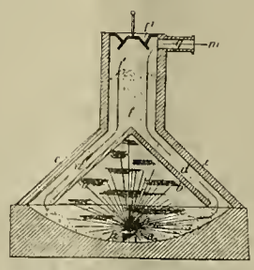
Apparatus for raising liquid by compressed air comprising closed chamber provided with liquid and air inlet and outlet, valve operating lever, float for actuating lever, two catches adapted to engage valve lever in raised and in depressed positions respectively, lever for operating catches, and float actuating last mentioned lever, catches being simultaneously operated through last mentioned lever and float, one to release and other to be free to engage valve lever as last named float reaches end of upward or downward stroke.

COMBINED CONCENTRATOR AND AMALGAMATOR.—No. 750,706; H. J. Russell, Crescent Mills, Cal.



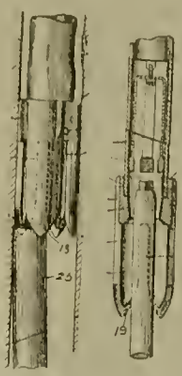
In concentrator, combination of flume, riffles arranged transversely on floor of flume, revolving catchers rotatively supported in flume and adapted to be rotated by flow in flume, screens placed at lower end of flume and arranged to receive discharge from flume, chute situated beneath screens, feed box supported near chute, and means whereby flow is conducted from chute to feed box, pivoted tables arranged to receive flow from feed box, tables having surfaces covered with woolly fabric, and concentrates tank beneath tables.

ELECTRIC FURNACE.—No. 750,753; R. C. Contardo, Sevres, France.



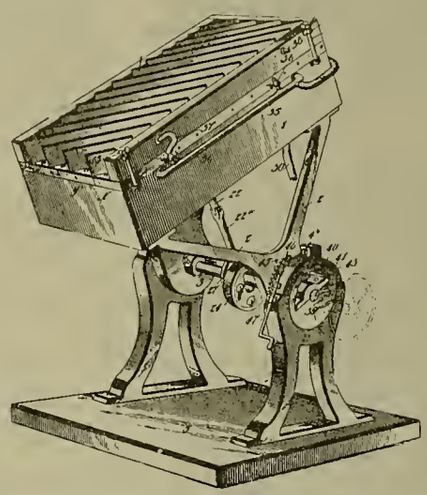
Electric arc furnace, comprising hearth having inclined surface, electrodes above same, arch above hearth consisting of two symmetrically and downwardly inclined surfaces, and side walls parallel to arch forming inclined flues, and vertical shaft above arch connected to side walls, and means for opening and closing charging opening of shaft.

FISHING TOOL FOR OIL OR LIKE WELLS.—No. 750,491; C. A. Sargert, Sheridanville, Pa.



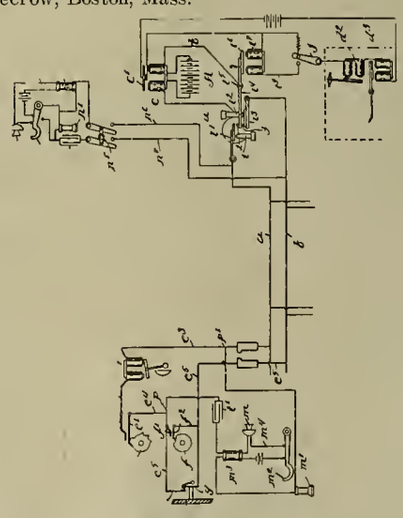
In fishing tool, head or socket, guide reins projecting down therefrom, guide reins having tapering ends and beveled inner edges.

PNEUMATIC DRY ORE SEPARATOR.—No. 750,366; E. M. Jahraus, Dayton, Ohio.



Ore separator box having pendent arms which are journaled on such axis, eccentric on axis, jointed piston rod connected with eccentric, air piston arranged in box and reciprocated through medium of piston rod, toothed arc formed on side of one of pendent arms, hand worm shaft journaled on one of fixed supports, its worm engaging toothed arc.

ELECTRIC SIGNALING APPARATUS.—No. 750,268; W. E. Decrow, Boston, Mass.



In electric signalling system, combination of battery and two main circuit wires a, b, leading from opposite poles thereof, constituting normally open circuit, signal receiving apparatus adapted to be operated by circuit, plurality of box-number circuit-operating devices, switch for each set of connecting wires for opening and closing it, means for operating switch, answer-back bell included in series with box-number circuit operating device in each set of connecting wires, and means for operating bell which is operated by signal receiving apparatus.

Mining Summary.

SPECIALLY COMPILED AND REPORTED FOR THE MINING AND SCIENTIFIC PRESS.

ALASKA.

Rich beach diggings are reported found on the tundra between Hastings and Little Derby creeks, 3 miles below Fort Davis, near Nome, and half a mile back of the present beach. These diggings are two claims wide and 2 miles long. As high as $2 per pan has been taken out, the ruby sand being 7 feet deep. Fifty men are putting up cabins in preparation for summer work.

Nome reports say the Norton Bay M. & Dev. Co. of San Francisco, Cal., has opened up high grade, white-quartz wash. Their property is so situated that they can work twelve months in the year.

ARIZONA.

Cochise County.

The Shattuck-Costello group of copper claims, near Bishee, is reported sold for $1,100,000 to A. M. Chisholm of Duluth, Minn.; M. Pattison of Superior, Wis.; A. Guthrie of St. Paul, and T. Bardon of Ashland, Wis. The property comprises 120 acres.

Graham County.

The average daily production of ore from the Detroit C. Co. stopes, near Clifton, is 700 tons, exclusive of waste, being the figure on ore going to the smelter and concentrator, says the Standard.

Work on the Coronado C. Co. group, near Clifton, is being resumed. The upper tunnel will be driven 200 feet, at which point it is expected the Coronado lead will be struck.

Mohave County.

At the Dempsy-O'Dea mines, near Chloride, one of the shafts has reached depth of 105 feet and is in ore. The owners will continue work on the group as long as it is possible to windlass out and then a hoisting plant will be built. Dempsy & O'Dea are owners.

The Vivian mine near Kingman, being operated by T. Ewing and J. Ross, of Los Angeles, Cal., is getting ore in bottom of shaft. A hoisting plant has been put in operation.

The crosscut from the bottom of the 400-foot shaft on the Gold Road mine, near Acme, has cut the vein and is showing 17 feet of the ore. The ore is being drifted on. J. D. Spargo is superintendent. The values are in free-milling gold. Additional machinery will be put in at the mine and it is proposed to enlarge the mill. Electric installation will be made at some point on line of Santa Fe Railroad, from which transmission line will be run to the mines for operation of all machinery. At present gasoline engines are used for power.

Yavapai County.

The Bradshaw Mountain C. M. & S. Co., which has mining interests at Middleton, has bought the Val Verde smelter for reducing the ores of the company. They will take charge of the smelter this month.

Superintendent Bowman of the Rainbow G. Co.'s property at Crown King has let 100-foot contract. The mill site is being prepared and the machinery will be installed in the spring.——The Crowned King M. Co. has made application to the Government for 4000 cords of wood to be used at the mine and mill.——At the Peck mine the work of unwatering is progressing. The main shaft is 500 feet deep with several long drifts.

The Dividend Con. G. M. Co., at Chaparral, reports the mill being enlarged.—— It is reported operations will be resumed on the Midnight Test mine at Groom Creek.

W. H. Bates, of Prescott, interested in the Welcome mines, 5 miles from Martinez, half way between Congress and Octave, reports ore struck in the Welcome at depth of 80 feet from the surface. The miners are raising.

Yuma County.

In Planet district in nortbern Yuma county B. Blanchard is working eight men on his group of copper claims 12 miles south of Planet. Two-horse whims have been set up and work is going ahead under superintendence of S. Butler. He will sink two of the vertical shafts on the group to depths of 200 feet and then crosscut for the ore bodies.——T. Chichester has men at work on the Mineral Hill group, owned by M. Pickerell of Prescott. ——C. Hawley has, the past six months, been steadily developing gold prospects in the quartzite belt, 2 miles from Planet.

On the Planet mine, owned by the Copper M. Co. at Planet, work is being confined to exploration of territory south of old surface workings which formerly produced high-grade copper ore. The drifts which have entered the hill over 300 feet beyond the old stopes, and at a vertical depth of 150 feet, have been run entirely in iron and copper ore. J. S. Jones is president of the company.

CALIFORNIA.

Amador County.

Robinson & Glenn, working the Whitmore mine, near Pioneer, have the mill in operation.

One hundred stamps are dropping at the Kennedy mine at Jackson—sixty in the new mill at the east shaft and forty in the old mill at the north shaft. The principal work is being done through the east shaft, the hoist there handling a 4-ton skip. Rock is being taken from the 2550, 2450, 2200, 2100 and 1800-foot levels, and about 250 miners are employed.

Calaveras County.

At the Columhus mine, near West Point, owned by B. A. McKinzie, near the Lone Star mine, the vein ranges from 2 to 5 feet in width. Owing to had weather, it is closed down till spring.

Del Norte County.

F. C. Marlowe, superintendent of the Haynes Flat mine, at Haynes Flat, near Crescent City, says little work has been done the last two weeks on account of snow. He is building flume and digging ditch, and $20,000 will have been expended when water is turned through the ditch and washing of the gravel deposit started.

El Dorado County.

The steam hoist on the Ida Mitchell mine, near Placerville, is in operation and sinking resumed in the double compartment shaft. The shaft is being sunk on incline and will pass the old workings of the Ida Mitchell. It is intended, says Superintendent D. H. Jackson, to go down 1000 feet and develop the ledge. Oil is being used as fuel and the buildings lighted by electricity. Measurements taken in the former workings show the ledge 12 feet wide.

Fresno County.

The Mt. Hamilton Oil & Land Co., which has been drilling at intervals near Alcalde station, near Coalinga, has again suspended operations indefinitely. —— After cleaning out well No. 2 of the Esperanza Oil Co., it has regained its former productiveness by resuming a flow of 400 barrels per day.

Rapid drilling is reported at well No. 3 of the New San Francisco Crude Oil Co. at Coalinga. Within thirty days the drill was penetrating oil sand at a depth of 1050 feet, having made that distance without mishaps.

The Monterey county board of supervisors has granted a right of way to the National Oil & Transportation Co. to build a pipe line from the Coalinga oil fields in Fresno county over highways in Monterey county for conveying products of Coalinga oil wells to tide water at Moss Landing. All the right of way over private property has been secured and the company will start work next week laying 6-inch pipe. This line will carry 10,000 barrels of oil per twenty-four hours from the wells.

Kern County.

The Uncle Sam M. Co. is developing the Hard Cash mine, near Randsburg.

Monterey County.

The Cavanagh oil well, near Bradley, is a 100-barrel well at a depth of 1400 feet, of 40° gravity oil.——The Combined Oil Land Co. continues development work on its land near San Lucas. J. D. Hoff, secretary, reports that its drilling outfit, working 9 miles from San Lucas, has a well down 640 feet, showing an oil-bearing stratum. They are prepared to sink to 2000 feet.

Nevada County.

The Omega Placer M. Co. has been incorporated to operate in Omega section, near Nevada City, with R. M. Wilbur, J. Underwood, F. W. Norwood, R. J. Beatty and J. Cheshire as officers.

After being idle for two weeks, during which time numerous repairs were made, the 3-stamp mill at the Rose Hill mine, near Grass Valley, is again in operation.

The trestle at the Murchie mine, near Nevada City, is completed, being 700 feet long, double track, and runs from the mill to the hoisting works. One thousand feet of pipe is ready to he laid to carry water from the hoisting works to the mill. The pipe will have 4-inch nozzle. The work of repairing the Banner ditch has been delayed on account of the rough weather. The ditch is 4 miles long and begins at the head of Little Deer creek.

A strike is reported made last week in the Ethel mine of the Gaston Ridge G. M. Con. Co., 7 miles above Washington, in God's Country, 27 miles north of Nevada City. A. Maltman et al. of Nevada City are owners. A crosscut tunnel 600 feet long was driven to tap the ledge at a depth of 300 feet.

An area of 150 acres of land at Jones Bar near Grass Valley has been bonded to T. J. and P. H. Leonard of Sweetland for $5000. They have had hauled there a quantity of 11-inch pipe and will convey water to the ground. The side of the hill will be sluiced off down to bedrock and in this manner they expect to uncover the vein.

In the New Eureka mine at Canada Hill near Grass Valley development work is progressing. The drain tunnel, which taps the incline at depth of 75 feet, is completed and drains off the large amount of surface water. The work of sinking the incline is going ahead and in the bottom there is a ledgo 18 inches in width. A station will he cut and drifts run both ways on the ledge.

Superintendent H. Kaler of the Grey Eagle mine, at Mayhert, says huildings are going up and operations ahove and helow ground will be started. Kaler has men extending the tunnel of the West Lindsey mine, which is owned hy A. H. Tickell of Nevada City. The tunnel is on the ledge.

Work was resumed at the Phelps Hill mine, near Nevada City, last week. E. S. & M. C. Irwin, C. A. Poage, A. H. Bayless, W. H. Murchie, L. A. Walling and E. E. Irwin of the company filed location notices on five claims comprising 450 acres of mineral and timher land at Phelps Hill, heing the Orion, Ajax, Fair View, Tiptop and Surprise Placer. These claims double the holdings of the Phelps Hill Dev. Co., says President Ketcham. Machinery for a sawmill will be set up on the property in the spring.

Placer County.

Work has started on the opening up of the Blue Lead gravel mine at Bangor. Men were put on last week. It is proposed to pump out some of the shafts, particularly the Catskill, and prospect the ground. If satisfactory, the work of driving the tunnel from Kentucky Ranch will be started. As considerable of the gravel is cemented, it is thougbt a stamp mill will be built near tbe mouth of the tunnel. Formerly the cemented gravel was handled by an arrastra.

Plumas County.

It is reported the Crescent mine at Crescent Mills will soon he unwatered and reopened.

At the Morning Star mine, on Nelson creek, near Quincy, Spaich & Co. have men on tunnel work. They are also drilling a raise from the tunnel to reach the channel.——The Continental mine has been equipped with plant and is ready for active work in the spring.——Gaspar & Anderson are running a tunnel to develop a back channel on east branch of Nelson creek.

San Bernardino County.

The Trio M. Co., near Manvel, has opened into a body of ore carrying native copper. This mine has 300 feet of tunneling and 100 feet of shaft.

Santa Barbara County.

The Brookshire Oil Co., operating 8 miles soutb of Santa Maria, reports striking a flow of oil in its well at a depth of 1900 feet. The property is north of the Pinal Co.'s holdings. The stream of oil shot out over the top of the derrick.

Shasta County.

Graphite deposits are reported located by F. H. Robertson and C. J. O'Brien, of Redding, in the hills 8 miles west of Redding. The ledge is 2 feet in width.

The Summit mine, a chrome property near Chromite, near Redding, has heen bonded to S. Gibson.

The Dry Slime mine, near the railroad connecting the Iron mountain mine and Keswick smelter, at Keswick, has heen bonded to A. M. McDonald of Oakland.

Sierra County.

The Alleghany M. Co. has bought the Alaska, Balsam Flat and other adjoining placer claims, near Alleghany. The mines have been under a bond to the company for some time. This gives them a large area of mineral ground covering several miles of the main channel.

Siskiyou County.

The Klamath G. M. Co. has located several quartz and placer claims on lower Humbug creek, near Hawkinsville, which will be opened up during the coming spring. Development work is progressing on the Punch Creek and McKinley quartz mines, and also the Spengler placer mines. —— Tbe warm weather of the last week, together with rain and snow, has started a good supply of water in the creeks and gulches. The placer miners are ground sluicing and operating hydraulic giants.

The New York mine at Indian creek, near Fort Jones, is heing worked steadily under management of J. B. Scott, by electric power for both mill and mine.—— A. C. Brokaw is working the Golden Eagle mine, also on Indian creek.

The ledges comprising the Punch Creek group on Humbug creek, near Hawkinsville, have been taken over by the Mono M. Co. and work will be increased during the coming spring and summer. They intend putting up a 12-stamp mill to operate hy electric power.

Fry & Macauley are developing the Sheba quartz mine at Patterson creek in Scott valley, near Fort Jones, with their mill in operation.

The Siskiyou M. & Dev. Association has closed down its coal mine, near Ager, as the machinery was unable to handle the large amount of water coming into the shaft. They will start up again hefore May 1st., after putting in heavier machinery. They have 100 tons of lignite coal on hand which will he used for fuel when operations are resumed. The mine is on the Southern Pacific Railroad, 3 miles south of Ager. The company has run an incline of 800 feet on the vein, and a vertical shaft of 145 feet cutting the coal at 2000 feet from where they left off on the incline.

Trinity County.

W. M. Walker and W. D. Miller of Hayfork have a hond on the Maple Creek group of quartz mines and are developing them. They expect to start the mill this month.

Tulare County.

The Fountain Springs section, between Porterville and White River, is heing opened up. J. M. Groves is developing claims in Fountain Springs gulch. A winze 100 feet deep has been sunk in the 75-foot level, showing a vein 18 inches all the way down, which assays $20 in gold. There are 170 tons of rock on the dump. Groves, with F. Marshall, is preparing to put in a 3-stamp mill and a 5 H. P. crude oil engine.

Tuolumne County.

An 8-foot vein of high grade milling ore has heen uncovered in crosscut, at 500-foot level, in the Golden Rule mine at Stent.

An air compressor will be placed at the Horse Shoe Bend mine near Columbia and machine drills operated. It is reported the company will hegin operations at the Arbona mine near Tuttletown, which has been idle for a year.

Fifteen men have been put to work at the Densmore mine, near Columbia, and prospecting will he done to relocate the ore shoot.

E. G. Kennedy has bought the Big Fern mine, situated on north side of Tuolumne river, 3 miles north of Jacksonville.

A 4-stamp mill is being built ou the Vivian and Concord group of the Republic M. Co., above Parrotts Ferry, near Columbia.—A. A. Irish of Los Angeles has honded twenty acres of the Trevithick ranch, above Sonora, and will prospect the mines thereon.—Operations on the Mt. Lily mine are expected to resume this month, says Superintendent C. Grimm. An air compressor, drills and other machinery are being put in.

Work is going ahead at the Vine Spring mine, near Columbia, and the stamp mill was put in operation last week, also the cyanide plant.

In main tunnel of Over mine, on Bald mountain, near Columbia, at point 1000 feet from mouth and 350 feet from surface, a station has been cut out and machinery is being set up for sinking on main shoot. The machinery will be run with water power and the 500-foot pipe line connecting same with ditch above by way of the stopes is in position. It will give 400 feet pressure.

The mill at the Del Monte mine of the Sierra G. M. Co., near Groveland, is crushing ore. In the mine work in the raise to connect with the west shaft is progressing. By this raise a body of ore is opened, the vein showing 8 feet in width. It is intended to raise from the 200-foot east drift to the surface, at distance of 250 feet from the shaft.

Work continues at the Hull mine, near Groveland. Drifting is heing done and ore is being taken out. Sinking will be resumed this month. The management has leased the Duleek plant and the mill will he started up next week. Fourteen men are at work in the mine under Superintendent A. J. Froehlich.

At the Dutch mine, at Quartz, the mill is in full operation with electric power. The ore is coming from the stopes above the 600-foot level south. The shaft is down 1480 feet and the 1400-foot level is being drifted south, being in 340 feet. Superintendent A. Trittenhach says he is drifting to connect with winze that is being sunk at the 1250-foot, and lacks ahout 25 feet of conuection. The shaft has heen retimbered from the 600-foot level up to collar. Fifty-five men are at work in mine and mill and 1800 tons is the monthly output of ore.

The Rawhide mine, near Jamestown, is running its 40-stamp mill by electric power.

Superintendent Hoskins is unwatering the Norwegian mine, near Tuttletown.

At the Jumper mine at Stent, Manager M. B. Kerr is running the 60-stamp mill by electric power. The new twenty stamps are housed and are expected to

be ready to run before March 1st. The concentrating room is completed, also the cleanup department. The ore bins are full and kept supplied from the mine by day shift alone. With the sixty stamps 5500 tons are reduced monthly. To obtain the rock needed for the additional stamps a few drills will be put on during night shift. There are twenty baby drills used in the mine. The compressors are not being run at night and mucking and timbering are mostly being done during those hours. Stoping is being done north and south from the main Jumper shaft from all of the levels above the 800-foot. Also ore is being taken from the middle vein of the Golden Rule mine and trammed through the 500-foot level to the Jumper shaft, there raised and sent to the mill. After connection between the two mines was made a crosscut was driven 250 feet to the foot wall, where the middle vein was struck, and it is being opened up. There are two grades of ore in this property. The proportion of sulphurets in the milling ore averages from 3% to 4%.

Superintendent E. C. Loftus, at the Santa Ysabel mine, near Stent, is sinking on the new shaft, and is down 370 feet. The shaft is of three compartments and an incline. It is proposed to send it down to the 2000-foot mark. It is said to be in diorite.

COLORADO.

Boulder County.

The Gold Nugget mill, near Rowena, is closed for the winter, but will be enlarged and reopened in the spring with double capacity, says the Eldora Record. The mine will be run all winter.

The Sugar Loaf G. M. & M. Co. has been formed with J. W. Enos of Boulder. The company's holdings are the Ragged Top, Lafayette, and Song Bird claims, near Sugar Loaf, held under bond and lease. The group joins the Livingston on the south. The vein is 7 feet wide, and carries values of $10 per ton with a shoot of tellurides. A gasoline engine, electric hoist and electric drills will be put in.

Oil has been struck on the Orcini ranch at 500 feet east of Otero well No. 1, near Boulder. The oil was struck at 1467 feet depth and rose to 600 feet high in the hole. Drilling was stopped in a fine-grained oil sand, and pumps will be put in. The well is owned by D. McDonald, D. Orcini et al. of Boulder.

Clear Creek County.

The Newhouse tunnel at Idaho Springs has been connected with the Cascade Electric lines, and hereafter what power is needed will be furnished by the electric company. Since the completion of the Gem raise, the air has become good throughout the tunnel workings, and a blower will not be needed. The Gem Co. has its own power plant, so that transportation of the ore and waste is all that the tunnel will be called on to do for the Gem.

L. S. Kenworthy of St. Louis, Mo., has bought the Pacific and other lodes in Jackson and Cascade mining districts, near Georgetown, for $50,000. Development will be started this month.

It is reported the Riley bond and lease on the Fred Rogers and Government lodes, near Georgetown, have been sold to the Kelly tunnel people for $2000. It is expected the Kelly tunnel will resume operations before April 1st, as during the last three weeks they have taken options on several properties along the course of the tunnel.

The Occidental Dev. Co. and its associate companies have been incorporated under the name of Occidental United Metal & Coal Co., organized under laws of South Dakota. The holdings of the new company comprise the Fraction group, gold and silver; at Idaho Springs, the Kitty Clyde, gold and silver, Idaho Springs; the Spandulix group, gold, Granite, Colo.; the Tamarack group, copper, Riverside, Wyo.; the Uranium group, in Montrose county, Colo.; the Duplex group, gold and silver, Spanish Peaks district, Colo., and the Occidental coal and fire clay lands, in Huerfano county, Colo. The officers are: E. L. Palmer, Danielson, Conn.; A. G. Boehm, Lawrence, Mass.; J. I. Davis, R. C. Miller, H. Robbins, O. S. Pierce and F. E. Hathaway.

Gunnison County.

At White Pine, the Akron tunnel is again being driven ahead. They are running two machine drills on the vein in the drift. It is reported the company will put additional machinery in the mill, and that they have bought the Tomichi valley smeltor.

At Bowerman the Independent mine has been bought by A. E. Reynolds and twenty men are developing the property under W. J. Fine. An air compressor and hoisting plant will be put in. The Independent G. M. Co. has been incorporated by J. C. Bowerman, S. Dunn, A. E. Reynolds and W. J. Fine.

Jefferson County.

Colorado Springs men, including I. W. Bonbright, O. B. Wilcox, J. K. & A. H. Robinson and G. R. Buckman, have incorporated the National Dredging Co. They propose to carry on dredging operations chiefly in Jefferson county, Colo., but also in Colfax county, N. M. The bed of Clear creek between Denver and Golden will probably be the object of first work.

Lake County.

The Huckleberry mine, in St. Kevin district, near Leadville, is making a showing under lessees. They have opened a body of silver-bearing ore from which shipments are going out.——The Golob concentrating mill in California gulch is being operated by W. F. Deaner et al., and they are handling thirty tons a day. This material comes from the Gilt Edge shaft No. 1, where a body of zinciferous ore is being mined.——Shipments from the Fitzhugh shaft on Fryer hill are steady, and Estey & Kyle, lessees, report improvement. The ore being shipped is sulphide, running 30 to 127 ounces silver per ton.

La Plata County.

(Special Correspondence). — With the mountains barren of snow until Jan. 21st, conditions in the La Platas have been favorable for work, and the mine managers have pushed work to the utmost, with the result that more mines are at present being worked and more men employed than at any time during the past fifteen years.

The Neglected mine, a producer of high-grade tellurium ores, and which has been shipping for two years, is milling its dump at a profit and shipping the usual amount of rich ore from the development work in the mine.

At the Bonnie Girl, the boarding house, bunk houses, store and flume have been completed and the frame for the mill is assuming shape. The first unit of the mill will be fifty stamps, which will be supplemented by 150 others as soon as the first unit has been perfected to the satisfaction of the management.

The May Day, the new prospect which was sold recently, is doing extensive building. The second payment of $10,000 was made early this month. The shaft is now 125 feet deep and drifting in both directions has begun on the 100-foot level. An air compressor and air hoist are to be installed and a tunnel started at the river level to tap the vein at depth of 500 feet. The vein is about 30 inches in width and averages well.

Another old mine is being reopened in the Comstock, the first location made in the La Plata district thirty years ago, and assays show that not all the rich ore was taken out. It was worked for several seasons after its location, but the rich gold chute was lost and mining became unprofitable, for the nearest smelter was at Pueblo, whither the ore must be hauled by ox teams. It has a record of over $60,000, and no stoping has been done farther than 40 feet from the shaft. The work of cleaning out the old shaft has been completed and it is found to be but 140 feet in depth. Drifting, crosscutting and sinking are going on, and good ore is being taken out, though the values are in silver.

Mancos, Jan. 28.

San Miguel County.

Near Ophir the Mary group, in Swamp canyon, owned by J. Manifold, J. W. O'Brien of Ophir and J. D. Gale of Boston, Mass., will be further developed. The group shows a vein of ore carrying a streak that runs high in silver and lead. Work on the foundation of a concentrating and amalgamating mill will be started this month.

T. W. Beam, manager of the Japan-Flora M. & T. Co., says he has fifteen miners at work on its group, near Telluride. Drifts on the Japan will be driven each way from the tunnel and a raise made connecting the tunnel level with the old workings. This raise will be 500 feet. The workings of the old Japan proper are filled with water. Until this work is completed, the working force will be limited to development on the tunnel level. The re-organized Japan-Flora Co., besides taking over the Ajax and the Valley View group, has also acquired mill site in the valley below the Pandora mill of the Smuggler-Union M. Co. It is intended to build a milling plant to be connected with the Japan tunnel by aerial tram. At same time development will be started on the Ajax and Valley View properties. R. W. Davis, Jr., is superintendent.

San Juan County.

A contract for 400 feet of extension on the Ruby tunnel in Ruby basin, near Silverton, has been let by the Ruby Basin M. Co.——Improvements are to be made in equipments on the Hercules mine and mill on Sultan mountain, near Silverton

Summit County.

The Old Union M. & M. Co. has been organized to operate on the Union lode and adjoining claims on Mineral hill, near Breckenridge. They will be worked through the Smith shaft. G. C. Smith is manager. The ore produced has shown values in lead, silver and gold. A shaft-house 50x75 feet is completed and machinery is being set up.

The coming season will see building of one or more gold-dredging boats to operate in the gold-bearing deposits of French gulch, near Breckenridge, says B. F. Hall, Jr., manager of the French Gulch G. M. Co. They propose operating a dredge in the placer pit they opened last season. The dredger would start on ground worth $1 a cubic yard and could operate for two months longer each season than the hydraulic plant, now in position at the pit. There would be sufficient water supplied by the company's ditches for a pond to float the dredger. Any time it might be considered desirable to clean up rough bedrock by hand labor the pumps on the dredger could unwater the pit. This property is a mile east of Breckenridge and 2 miles from the mouth of French gulch.

It is also said H. Farncomb et al., interested in the Wire-Patch group, 5 miles east of Breckenridge, up French gulch, expect to build a dredger to work the placer ground up French gulch from Lincoln City. Manager Farncomb will have the ground to be dredged prospected with churn drills to determine width and general direction of pay channel. Besides placer ground, the Wire-Patch M. & M. Co. owns several gold lodes on Farncomb hill, contiguous to the placer ground.

G. C. Smith, A. E. Keables et al. are preparing to increase work on the Union mine, near Breckenridge. An engine, boiler and hoisting drum are being placed on the shaft.——C. Kaiser, F. Case and W. H. Foster are working under a lease in the Germania tunnel, on the Germania mine.

Teller County.

The strike of high-grade ore made by Lessees Harrison & Selver on the W. P. H. claim on Ironclad hill, Cripple Creek, is showing the shoot averaging 21 inches wide, carrying native gold and sylvani e. —— A bigh-grade shoot of smelting ore has been opened up in the tenth level of the Granite mine, owned by members of the United States R. & R. Co.

The Rio Grande sampler in Victor is treating an average of 150 tons of ore per day with one shift consisting of sixteen men. Beginning this week, another shift will be put to work and the treating capacity doubled. All other samplers of the district are running full-handed.

The Ella M. Co., which owns the Ella M. claim and others near Gillett, reports development work progressing. They are sinking a shaft and doing lateral work. There have been opened up several veins of low-grade ore which can be treated with the cyanide process. Several tests having been made, the management intends building a cyanide mill.

A strike is reported made last week in the Colorado Boss group, on the southwest slope of Gold hill, at Anaconda, through the Anaconda tunnel, by Crowder & Stevenson. The lessees have 2 feet of ore in a crosscut 300 feet from the tunnel. The ore runs ten ounces gold per ton. There is sylvanite in the rock. The Colorado Boss mine is owned by the Cripple Creek Con. Co.

The Hyde Park City district, 6 miles west of Cripple Creek, is largely deserted, says the Republican. Only one prospect is being worked. McMurray & Son are sinking a shaft in the wash and report encouraging assays from depth of 75 feet. They propose to put the shaft down to the 100-foot point before the end of winter.——The cyanide mill built by the Mount Pisgah M. & M. Co. on its property in Hyde Park district, is being dismantled for removal. The tanks, stamps and other machinery will be shipped into Cripple Creek.

The United G. M. Co. has granted lease to H. Hart on west portion of Hardwood claim, near the W. P. H. Co. on Ironclad hill, Cripple Creek. The ground also adjoins Schoernherst & Co., who are leasing on south end of the Damon. Lessee Hart will sink a shaft and at depth of 100 feet expects to crosscut and drift.

The Matoa M. Co., which has resumed work on company account on the Half Moon mine on Bull hill, Cripple Creek, is being bothered with water question. If the water does not recede materially during the next few weeks it is expected the company will either close down and wait for the drainage tunnel to benefit them or they will commence lateral work at their lowest point. The water is receding at rate of 4 inches per day. The company started sinking a shaft on the 800-foot level, expecting to go to the 1000-foot point before beginning lateral work, and after going 75 feet water has been struck, which prevents further sinking unless pumps are used.

IDAHO.

Custer County.

The White Knob M. Co. has completed the erection of twenty-one dwellings for accommodation of those employed at its mines and smelter at Mackay, the payroll showing 380 men. The smelter is daily reducing 500 tons of copper-bearing ore. In addition, high-grade rock is being shipped to outside plants, the matte from the company's furnace also being shipped. In the mines the tunnel is showing up the ore bodies. —— The McCollum group in Rio Grande gulch, near Mackay, is under development, as is the McGinty group on White Knob peak.

Kootenai County.

W. E. Smith of Duluth, Minn., president of the Antelope M. & M. Co., says, at their mine near Clark's Fork, in Peud d'Orielle district, the tunnel has been driven 90 feet and is in lead-silver ore. The ledge is 5 feet wide between the walls. More men will be put to work.

Shoshone County.

Deeds to mines in the Cœur d'Alenes were passed last week, the Federal M. & S. Co. taking over titles to the Standard and Mammoth at Wallace and the Empire State-Idaho properties at Wardner. It bought the stock in those companies last fall. It is said to have paid a total of $1,875,000 in cash and $10,462,500 in Federal stock (common and preferred). The deep level strike in the Standard mine is showing up well. The face is 18 feet wide and shows ore running 15% in lead, says President C. Sweeny. It will concentrate 5 or 5½ in 1 and will carry fifty-five ounces of silver in the concentrates. The shoot has been drifted on for 250 feet. In the level above it the ore shoot is 1000 feet long.——Ore is being taken from the 1900-foot level of the Tiger-Poorman mine at Burke. The vein is 20 feet wide and has a 5-foot shoot. They are running levels every 200 feet, instead of at 100-foot intervals, as formerly.

Reductions are being made by the American S. & R. Co. to the Cœur d'Alene mine owners for treating silver-lead ores of the district. Under the old contracts the mine owners have been paying $18 a ton freight and treatment on most of their ore, and have been getting only 3½ cents a pound for the lead contents, although the New York price on 50-ton lots has averaged about 4¼ cents. The large Cœur d'Alene interests have been demanding a readjustment of prices, by which they will be paid 90% of the New York quotations, instead of an arbitrary price. The smelters have always made an arbitrary deduction of 10% of the lead contents of the ore for alleged losses in smelting. That practice will be continued under the new arrangements. Practically, therefore, the mine owner will receive 90% of the value of 90% of the gross assay lead contents in the ore. The miners are not asking a lower smelting rate, which will remain at $8 per ton.

Washington County.

The Pactolian M. Co. at Iron Springs, near Weiser, owing to bad air in the tunnel which was being run, has suspended operations temporarily until arrangements can be made to drive out the foul air. The company has set up an engine on the ground, which will drive a blower.

Two rates for moving of ores from Washington mines to smelters of that State have been made by the railroads. One is the rate made by the V., V. & E. and the S. F. & N. in connection with the Great Northern or Northern Pacific for ores from Republic camp, Ferry county, to the coast, says the Spokesman-Review. This tariff provides that on ores from that camp, where valuation of product is less than $100 per ton, the freight to Seattle, Everett or Tacoma, Wash., or Liverpool, B. C., will be $4 per ton. The other rate is made by the Northern Pacific, in connection with the Great Northern, via Adrian cutoff, from points along the Washington Central branch. From Coulee City, Hartline, Almira, Wilhur, Creston, Davenport, Reardan and Medical Lake the rate to either Tacoma or Everett is $5.50 per ton. This also limits the rate to ores of no greater value than $100 per ton. Both these rates apply only to carload lots of 30,000 pounds minimum.

KANSAS.

Neosho County.

(Special Correspondence). — Less than two years ago drilling started in Chanute oil district and there are at present twelve to fifteen companies paying dividends. The Colorado-Kansas Oil, Gas, L. & M. Co., with offices in Chanute and Colorado Springs, Colo., has a lease on 400 acres and has two flowing wells. Work has started on well No. 3. The two finished wells are less than 800 feet deep. A pumping plant will be built as soon as No. 3 is completed. The product sells at $1.37 per barrel at the well. The Standard pipe line has been completed to the properties.

Chanute, Jan. 30.

MICHIGAN.

Keweenaw County.

The third head of stamps at the Mohawk mill, near Allouez, is in operation. The other three are being repaired. The rock house is in use. The daily output of shafts No. 1 and No. 2 is 1000 tons, and there are 300 drills operating. It is reported that the Mohawk and the Ahmeek properties may be consolidated. It is said a union of these would free the lands owned by both from every disadvantage in the removal of vein matter, besides reducing operating costs. The Mohawk shafts would become tributary to the entire adjoining Ahmeek tract to the west, permitting its being mined to fullest advantage, whereas under existing conditions the latter property can only be reached by vertical shafts, which would have to be extended to considerable depth. The Ahmeek tract consists of 920 acres, but the location of boundary lines with regard to the strike of the lode is such that only two shafts can be sunk from the surface on the plane of the formation, and these are already under way. They are located at the south end of the property and 1440 feet apart. The Mohawk, on the other hand, comprises 800 acres of land, of which the Kearsarge lode underlies 600 acres, and in addition to this it traverses the tract for a distance of 10,000 feet. Present boundary lines prevent the obtaining of maximum depths at the Mohawk shafts, particularly those to the north.

Ontonagon County.

The annual report of the Victoria C. M. Co., operating at Victoria, shows the amount of ground opened during last year was 5037 feet—total to end of 1903 being 25,337 feet.

MISSOURI.

Jasper County.

At Kendricktown, north of Carthage, the drill hole is completed on the land of E. J. Palmer. The hole was stopped at 163 feet, after going through 26 feet of lead and jack mixed. The jack found is rosin jack, free of all mundic (iron sulphides). The drill has been taken some distance away to prospect other portions of the lease in search of other leads. An adjoining forty acres, the Harp land, has also been leased by the same company, which is composed of S. Qualls, R. A. Mooneyham, R. Elliott, T. R. Nicholas and J. W. Gray.

Work in the Cleveland Circle mine at Oronogo will be resumed this month, after being idle a year. Ore was struck in the bottom of this shaft, but the water drowned them out.

At Carl Junction, Gates & Nail are shipping ore.——Four tons of ore per shift are being made at the Daisy Bell.——At the Seven Devils a large head frame has been built over the new shaft and a tramway built from it to the plant. The shaft is 100 feet deep, in ore, and will begin producing this month.——Work has been renewed in the Ishpeming mine C shaft. The Ishpeming new shaft is completed. Pumps and other machinery are in and ready to run.

MONTANA.

Madison County.

In Norwegian mining district, near Pony, Duncan Bros. are retimbering the shaft at the Elephant Tail claim and propose putting in machinery to sink below water level. They are down 20 feet below water level.

The Conrey Placer M. Co. has bought the Van Brocklin ranch, near Virginia City, for $10,000. The company is planning for an electric power plant to be built near Alder.

Fergus County.

The J. Burke one-half interest in the Burke-Sweeney eight sapphire claims near Yogo has been bonded to H. Cruttenden for $15,000. It includes all water rights and appurtenant privileges. The claims are the Fourth of July, Victor, Klondike, Kelly, Hope, Gem, Minna and Line claims, which join the properties of the New Mines Syndicate on the south.

Silver Bow County.

The Montana Supreme Court on the 1st inst. reversed the decision of Judge Clancy, of Butte, in the injunction suit of J. MacGinnis against the Boston & Montana C. Co., which caused the shutdown of the Amalgamated properties last summer. The case involved the injunction issued by Judge Clancy against the Amalgamated C. Co.'s holding and voting stock in Montana companies. The decision will release the Boston & Montana dividends, provided the Supreme Court does not grant a rehearing.

NEVADA.

Esmeralda County.

(Special Correspondence).—At Goldfield a strike of high grade ore was reported this week in the January claim, which joins the Combination mine on the west. The vein has been opened for 6 feet. One feature of the strike is that it was made under the leasing system, which has been inaugurated at Goldfield. Lauka, Warner & Duval have subleased the February claim. Patrick, Jones & Kendall have both the January and February claims under lease.

At the Combination mine, in sinking the 5x8 shaft 80 feet and drifting 40 feet, it is said to have produced its purchase price ($75,000). The east drift is in 50 feet and the values average $150 per ton. Shipments continue. The company intends to build a reduction plant, which, it is thought, will use the cyanide process.

Myers & Murphy have their shaft on the Silver Pick group down 35 feet and values are satisfactory. The group is north of the Combination. At depth of 60 feet they intend to crosscut for the main vein.——Four leases have been let on the Florence group, which adjoins the Combination on the southwest. J. P. Sweeney and L. L. Patrick have opened up ledges on their leases, the rock panning free gold.——Kane & McMahon have a ledge on their group opened up in three places. This is 4 miles north of the Combination.——J. P. Harvey, for P. Clark of Spokane, Wash., has a bond on a group adjoining, which has extension of same ledge. Harvey has been doing development work.——J. H. Spiking has made a strike of ore showing free gold near Kane Spring, 8 miles east of the Combination.

Clarke & Barnes propose building a mill to treat custom ores, and have secured options on several water rights and millsites.——Goldfield has been connected with the outside world by telephone and telegraph, and the population in four months has increased to 400.

Goldfield, Jan. 31.

The Montana-Tonopah M. Co. at Tonopah reports that the main shaft of the Montana has reached a depth of 695 feet, and will be sunk to 755 feet, where a station will be established and a crosscut started north. The north crosscut from the 612-foot level is in 415 feet. The east and west drifts on the McDonald ledge on this level are showing up ore, and on the same ledge in the 517-foot level a drift to the east has been started. The west drift is in 222 feet and shows a face of shipping ore. A scarcity of teams the past week or two has interfered with the shipment of ore.

At Goldfield, south of Tonopah, the Goldfield M. Co. of Nevada has been incorporated under Arizona laws, with R. L. Johns, M. N. Clark, H. T. Bragdon, A. C. Eisen and W. M. Stansbury as directors. The company owns the following claims in Goldfield mining district: January and February, adjoining the Combination; September, half a mile south of the Combination; October and St. Paul, adjoining the September, and the Henry Clay and Cracker Jack, on the same ledge as the Columbia.——A number of leases have been let during the past two weeks on the Florence group, adjoining the Combination on the east.

Work has begun on the Douglass mines, near Tonopah. The first work will be an extension of the Curtis tunnel, which is in 127 feet on the Snow Ball claim. Another 60 feet is expected to carry it into the body of ore which was followed from the surface to within 40 feet of the tunnel level. Work has been resumed in the Bounce mine at Douglass and a raise is being opened from the 400-foot to the 300-foot level on the ore body.

Lincoln County.

The Southern Nevada M. Co. at Searchlight will put in a cyanide plant to handle the mill tailings, says Manager Perew. It will have 100 tons daily capacity.

Storey County.

Drill hole No. 7 in the Occidental mine at Virginia City is down 440 feet and last week cut quartz and porphyry, the quartz showing gold and silver values. In the Edwards location of the Occidental the east crosscut No. 3 on the 550-foot level shows improvement, the ore in the face assaying $24 per ton in gold.

The management is preparing to put in pressure and discharge columns for the water elevator system in the C. & C. shaft at Virginia City, and, as soon as the shaft is cleared of the old pumping system, the pipe will be lowered to the 2550-foot level and the shaft cleared of water.——Repairs to the shaft at the Silver Hill mine have been completed and work will begin this week in that part of the mine.

OREGON.

Baker County.

E. Cleaver, of Sumpter, interested in the Myers group, near Medical Lake, operated by the Indiana M. Co., says the hoist is in operation. Pumps were also put in. The hoist has depth capacity of 500 feet. The shaft was sunk 80 feet by hand on the ore body. J. W. Messner, of Sumpter, is manager of the company, and also of the Prairie Diggings mine, operated by same people.

G. M Anderson, of Inwood, Iowa, president of the Keystone M. Co., reports operations progressing at the Keystone group, Quartzburg district. It is the purpose of the company to put in additional machinery. Sinking will be continued by hand for a short time, and a hoisting plant will be built. H. Hendryx of Sumpter is manager.

Preparations are being made to put up a milling plant at the New York mine, near Greenhorn. Superintendent C. C. Nepple says work is going ahead satisfactorily, the vein improving as depth is attained.

The Auburn Deep M. Co. of Sumpter is resuming work at the Auburn placers, owned by this company at Auburn. J. Reed is superintendent. They will run a crosscut from the 100-foot level in the shaft northward, to cut the pay channel at its lowest point. In sinking the 240-foot shaft, at depth of 87 feet, a pay channel was struck. This was covered to depth of 3 feet with a black loam and beneath was 6 feet of gravel. The channel pitches north. A prospecting drill will be put to work.

Grant County.

Manager Wright of Sumpter, of the Blue Bird mine, and also of the Black Butte, says Superintendent E. C. Allen reports work of overhauling in the latter mine progressing. It has been several years since the Black Butte was operated. On completion of this preliminary work it is intended to put in a hoist with 500-foot depth capacity. The plan is to make a raise from the main working level to the surface, a distance of 80 feet, then put in a hoist and begin sinking. This property is near Prairie City. At the Blue Bird the number of men underground has been increased.

Jackson County.

J. W. Opp is taking out ore from the upper ledge of his mine on Jackson creek, near Ashland, and has started his quartz mill in operation.

After four months' work the landslide at the Sborty-Hope mine workings, near Ashland, has been overcome, and the property will be further opened up. They will let contract for 350 feet of drifting on the Golden Spike claim of the company.——It is reported the Montreal & Oregon G. M. Co., which owns the Ashland mine, west of Ashland, is preparing to resume operations.

Josephine County.

The Galice Con. M. Co., near Grant's Pass, is operating several giants on Galice creek this winter. One of them is working near mouth of creek. This ground was idle for several years on account of lack of water to work it properly. D. Green, foreman, says next season it is expected the company will open the creek at the mouth and sluice out entire contents of creek bed.

In Grave Creek district, near Grant's Pass, the Vulcan mine has been equipped with machinery and is crushing rock. A 10-stamp mill has been built. The Vulcan is on Browning mountain and near the Greenback mine.

The Wolf Creek M. & Dev. Co. is carrying on operations in both placer and quartz properties on Wolf creek near Grant's Pass. The creek bed is being worked for distance of 6 miles of its course. On the ledge which is under development men are running a tunnel which follows the vein, having width of 7 feet.

SOUTH DAKOTA.

Custer County.

The Mile High M. Co. has started operations on its mines, west of Custer.

Lawrence County.

H. J. Mayham et al. will develop a group, recently bought, at the bead of Elk and Bear Butte creeks, 5 miles south of Lead. The group includes thirty-two claims.

UTAH.

Beaver County.

C. Rae of Chicago, Ill., has an option on the Talisman, Stalwart and San Juan patented claims near Milford, and on three patented claims in Granite range, which include the Roosevelt Hot Springs. The option is for ninety days for $200,000. Men will be put to work this week. The first-mentioned group is in Star district.

Juab County.

The Uncle Sam Con. C. Co. of Tintic has begun shipping concentrates from its mill, near Eureka, which are said to assay 35% lead and 20 ounces in silver, with some gold. The management is also shipping first-class ore.

J. Knight, operating the Salvator mine on Godiva hill, near Eureka, reports he is shipping ore.

Salt Lake County.

(Special Correspondence). — The Ohio C. Co. started its mill at Bingham on the 23rd. They are daily sending 150 tons of ore to the mill and about 50 tons of first-class ore to the smelter. O. A. Tibbets is manager of the company and T. A. Varden superintendent.

Bingham Canyon, Jan. 31.

The name of the company operating the Bingham-Centennial mine at Bingham has been changed to the South Columbus M. Co.

The United States smelter at Bingham has its entire battery of five furnaces in operation. Plans for the new lead smelter which the company proposes to build are progressing and work on grading and construction is expected to begin this month.

The Winnamuck mill (remodeled) has resumed operations. The Copper Belt railroad extension to its hins was completed last week. The daily capacity is 150 tons. At the mine, 3000 tons of concentrating ore that carries an average of 4% copper has been broken in doing recent development work.

Iron County.

The Johnny mine at Stateline will resume this week. The mine is said to be showing improvement.

Morgan County.

J. E. Hartman of Park City, vice-president of the Park City Co-operative M. Co., says he will start work this week on the Copper Mountain group, owned by the company, in Morgan county.

Summit County.

The Koarns-Keith concentrator of Park City is in full operation, handling an average of fifty-five tons of ore per day, from which fourteen tons of silver-lead concentrates are produced. Four more concentrating tables are to be set up; these, however, will not increase the output of the mill to any material extent, but will enable the plant to handle its present tonnage with greater ease. It is the intention of the company to ultimately increase the capacity of the plant to 700 tons a day.

Manager W. P. Jenny of the Woodside mine, near Park City, reports recovering the ore body which they had for a time lost track of. Assays show, silver 30 ounces, lead 40% and gold $5.

Work is being done at the Park Summit mine, near Park City, under J. E. Lucy. It is north of the Scottish Chief and is owned by J. H. Rinley et al.

Washington County.

The Utah & Eastern M. Co.'s Dixie mines and smelter, near St. George, are maintaining steady output of copper and six tons of bullion are coming from the furnaces daily.

WASHINGTON.

Ferry County.

Superintendent C. Hill reports work continues on the Taylor group, north of the Tom Thumb mine, near Republic. It is owned by Seattle men.——A drift is being driven on the 140-foot level of the Nob Hill mine and work on the raise is being hurried to secure better ventilation and admit of more rapid stoping. Ore shipments continue.

WYOMING.

Albany County.

Pitchblende has been found in Halleck canyon district, east of Laramie. The Arena M. Co., composed of Denver, Colo., Salt Lake City, Utah, and Laramie men, has been working fourteen claims in Halleck canyon for the past eight months.

FOREIGN.

The world's output of tin for 1903, compared with 1902, is reported by W. T. Sargent of London, England, as follows:

Shipments from Straits Settlements to Europe and America:

	1903. Tons.	1902. Tons.
January	4,685	4,035
February	3,437	4,363
March	5,465	4,642
April	3,296	4,022
May	5,602	4,182
June	4,846	4,984
July	4,641	3,710
August	5,181	5,190
September	4,481	4,808
October	4,188	3,790
November	3,806	4,335
December	3,175	3,770
Totals	52,215	51,831
Shipments from Straits to India and China—January-December	3,150	1,925
Totals from Straits	55,365	53,756
Shipments from Australia	4,157	3,206
English production	4,300	4,300
Bi-monthly sales of Banca and Billiton	18,900	19,000
Bolivian exports to Liverpool and Continent	9,790	10,150
Totals from all parts	92,512	90,412

AFRICA.

Rhodesia.

The gold output of Rhodesia for month of December amounted to 18,750 ounces.

Transvaal.

The Transvaal Chamber of Mines at

Johannesburg gives the following corrected figures for output of gold in fine ounces for 1903, compared with 1902:

	1903			
	Rand. Ozs.	Outside. Ozs.	Total. Ozs.	1902.
January	192,934	6,345	199,279	79,341
February	187,027	8,526	195,553	81,105
March	208,456	9,009	217,465	104,127
April	218,900	8,971	227,871	119,389
May	221,109	9,716	234,125	138,602
June	228,167	10,153	238,320	112,780
July	242,070	9,573	251,643	140,179
August	262,569	9,349	271,918	162,750
September	267,513	8,684	276,197	170,802
October	275,664	8,880	284,544	181,440
November	272,107	7,706	279,813	187,375
December	278,710	7,351	286,061	196,023
Totals	2,859,476	101,273	2,963 719	1,705,413

AUSTRALIA.

New South Wales.

At Neeld's Proprietary mine at West Wyalong an additional 160 feet is being sunk from the 400-foot level. It has been decided to abandon working of vertical shaft on the underlay. A cyanide and crushing plant capable of treating 420 tons per week has been built and will be in operation this month.

The Victorian company, which bought the McGregor claim at the Bark Hut goldfield, near Gundagai, has completed a ten-head battery, which is in operation.

Victoria.

Melbourne reports say the geld yield of Victoria for year 1903 was 822,424 ounces, being an increase over 1902 of 44,686 ounces.

Western Australia.

In consequence of the shortage of water at the Sons of Gwalia mine, near Leonora, it is intended to sink a water shaft 2½ miles east of the mine, where it is thought sufficient supply will be obtained. On two or three occasions recently delays have been caused through there not being sufficient water for the boilers, though amplo is available for milling purposes.

The total gold yield of Western Australia since the first records were kept (1886), up to Jan. 1, 1904, has been 12,208,704 ounces, valued at £45,713,579.

Recent development work is reported to have increased the Kalgurli mine tonnage of ore reserves at Kalgoorlie. The deepest level is at 1050 feet, but a winze is being sunk below that point on east side of the ore opening up at the 1000-foot level. The average grade of rock taken from the winze is 17 dwts. per ton. Northward, free gold with streaks of telluride are showing in face of workings. At the 1000-foot level the south drive parallel with the eastern boundary is going ahead. The face of this drive is 100 feet distant from the point where it is thought the Brownhill-Oroya shoet enters Kalgurli ground. The work of driviug through the intervening ground is expected to be finished by March 1.

The main ore body of the Great Boulder mine at Kalgoorlie has been crosscut at the 1750-foot level. Once more the results foretold by diamoud drill—heing obtained from hore-hole prospecting in this mine—have been confirmed by bulk sampling, says the Western Australia Journal. The existonce of 30 feet of high-grade ore at vertical depth of 1750 feet is proven.

BRITISH COLUMBIA.

The report of the Bureau of Provincial Information for the year 1903 says that in addition to labor troubles there were other couditions that affected mining progress during the year. During February and March the copper mines and smelters of Kootenay, Rossland and Boundary districts were partially shut down by the strike of coal miners at Fernie. Later the coal miners of Nanaimo, Extension and Cumberland, on Vancouver Island, struck, lasting into August. In the Kootenays not only coal and coke, but gold and copper production was restricted. In the Slocan and East Kootenay the situation, as regards successful mining deposits of silver-load ores, has not heen encouraging for some time, the sole reason heing high cost of marketing the product since the American market was closed to British Columbian producers. In the early part of 1903 the decline in the price of metals also interfered. Carihoo, Atlin and Omineca districts suffered from shortage of water supply. In the summer affairs changed for the hetter, and since then there has been ahundant evidence of a general revival of mining in the Province. During the last six months of the year the production of copper-gold ores aud of coal has heen greater than ever before, and many mines are being reopened and equipped with machinory.——Atlin district's gold production in 1902 was 20,000 ounces, value $400,000, and the estimates for 1903 show an increase to $450,000.——On the Fraser river, at Lytton, two dredgers have heen operated with success.——The gold yield in 1903 from Carihoo is estimated at hetween $300,000 and $350,000, or 25% to 30% less than for 1902—attributahle to the shortage of water supply.——In the Lardeau, in every instance the positien of the more important mines has improved. Considerable machinery has been put in, notably a 20-stamp combination silver mill at the Silver Cup, aerial tramway at the same, aerial tramway of 8000 feet length at the Great Western, and stamp mills at the Eva and Oyster Criterion mines at Cambourno.——The Slocan shows for 1903 the lowest eutput since the beginning of the district as a producer, being but 14,000 tons of galena and 2000 tons of zinc ore. Since the Govornment granted a beunty on lead productien last summer a number of mines have been reopened. This will assist the 1904 production.——Rossland's production of approximately 400,000 tons during 1903 is an increase of 20% over 1902.——The production of approximately 700,000 tons hy the Boundary district is an increase of 25% over 1902.——On the who'e, the general outlook for British Columbia for 1904 is promising. The following is the Bureau's estimate of the output for 1903:

METALLIFEROUS MINES.

	Tons.
Coast	100,000
Slocan	16,000
Nelson	50,000
Rossland	375,000
Boundary	685,000
Other districts	50,000
Total	1,276,000

COAL MINES.

	Tons.
Vancouver Island collieries	870,149
Crow's Nest Pass Coal Co. (coal)	650,000
Crow's Nest Pass Coal Co. (coke)	166,000
Total	1,686,149

ESTIMATED VALUE OF MINERAL AND COAL PRODUCTION, 1903.

Gold (placer)	$ 900,000
Gold (lode)	6,000,000
Silver	1,500,000
Lead	500,000
Zinc	50,000
Copper	4,500,000
*Coal and coke	5,250,000
Miscellaneous	500,000
Total value	$19,200,000

*For the purposes of this estimate, coal is valued at $3 a ton and coke at $4.

Boundary District.

The Granby Smelter Co. of Grand Forks has a hond on the Shamrock III and Reliance mineral claims in Summit camp. Development work has hogun. The Shamrock III and Reliance adjoin the Senator and Fromont, which were bonded by the smelter company in Decem her. Ore from the Senator is heing shipped to the smelter, quarried from a glory hole on the surface.

East Kootenay District.

Montreal men have incorporated the Imperial Coal & Coke Co., Ltd., to operate 88 square miles of coal land on Fording river, north of the areas owned hy the Crow's Nest Coal Co. at Michel and Fernie.

The Crow's Nest Pass Coal Co. output of coal for 1903 was 661,118 tons at Coal Creek, Michel and Morrissey, as compared with 441,236 tons for 1902; and the coke output was 167,739 tons, as against 120,777 tons in 1902, reports D. Davis, comptroller of the company. Last year there were 424 coke ovens in operation at Coal Creek, 341 at Michel and 148 at Morrissey and the company has under construction 123 more coke ovens at Michel, 92 at Morrissey, making a total of 1128 ovens. He states that the mines are heing steadily developed with view to increasing output. Tho output last year was affocted by the striko, which closed operations in February and March.

Rossland District.

Amalgamation of the companies owning tho Velvet and Portland mines on Sophie mountain, near Rossland, is being negotiated. It is expected with resumption of operations the reduction works will he built, and the pyritic smelting method used. Tho Rossland-Velvet wagon road is expected to be completed.

CANADA.

Ontario.

The nickel of the world is at present derived principally from two sources—Sudhury district of Ontario and New Caledonia, a French penal colony in the southern Pacific ocean.

Yukon Territory.

A second pay streak, which is said to parallel the first found on Lower Dominion creek, in Klondike district, has been struck on the lower henches opposite 235 below, according to Dawson reports. J. H. Powell, one of the men who mado the strike, says the new pay streak is in the third tier. The first found pay streak is on the first tier of henches. Both are on the right limit. The gold in the second pay streak is not high grade, hut of sufficient quality to warrant working. Other miners along Dominion creek are sinking shafts to find pay gravel on second and third tiers of thoir mines. Last winter second hedrock was found on Three A, El Dorado fraetion, but the shaft filled with water and drove miners from work.

MEXICO.

Chihuahua.

J. S. Sullivan, manager of the Santo Demingo and El Potosi mines of Santa Eulalia, has bought the Tres Mercedes, Promontorio and Santa Eulalia mines in same camp for $100,000 gold. Development work will be started this month.

J. T. O'Hara of the Shoo M. Dev. Co. of Colorado says he has an option on mining ground 10 miles west of the Santo Dominge mine, of the Corralitos Co., near Sabinal station, on the Sierra Madre Railroad.

It is reportod the Santa Eulalia M. Co. (Hearst) proposes building an aerial tramway from its mines at Santa Eulalia to the Mexican Contral Railroad.

The Palmilla mine of P. Alvarado, at Parral, has yiolded bullion during the last three years to value of $500,000 gold, says the Chihuahua Entorpriso. Alvarado has 20 feet of high-grade gold and silver ore.

Parral reports say the Adela mine of W. Petit, in Santa Barbara section, has been sold for $2,000,000 geld to G. Beckman, of Parral, and J. B. Hyslop of the San Francisco del Oro mine. The Adela is equipped with mill, tram and other machinery.

W. P. Dunham et al. of Denver, Colo., who hought the Pinos Altos mines, near Ocampo, will increase the capacity of the mill and put up additional reduction works.

T. H. Oxnam of Los Angeles, Cal., manager of the Palmarejo and Mexican G. F., Ltd., mines at Palmarejo, says machinery is on the ground for the slimes plant.

D. R. Morgan, mine manager of the Torreon smelter, says they have closed down the Americano mine at Terrazas camp, hauling to the station all the ore that was out. He says the company has mined only enough rock to be sure of sufficient fluxing ores for its smelters, and that at present it has lead ores that can he mined cheaper than those of the Americano. In the ten months the mine has been worked hy the Torreon smelter 15,000 tons of ore havo heon taken out of shipping grado. The ore was practically quarried out and with no waste.

Dale Bros. and F. McDonald are again owners of the Americano mine at Terrazas and have started taking out ore for shipment.

The Tecolotes mill of the Guggonheims at Santa Barhara is shut down temporarily for installation of electric machinery. Electric power will he suhstituted for the gas engines, and it is said gas will he used as fuel. The narrow gauge ore railroad will be changed from steam to electricity.

Parral camp is shipping 10,000 tons of ore monthly to the smelters, and this could he increased 50% if the Mexican Central could supply cars, says the Chihuahua Enterprise. The patios of the ore-huying firms are crowded, and it is estimated that there are 750 cars of ore waiting transportation. Notwithstanding the falling off in tonnage shipped the last few months, the value is largely made up in increased grade of ores, due to improvement of ore in depth and the more extensive working of hetter grade mines.

Coahuila.

O. S. Newell of San Antonio, Tex., of the Jimulco C. Co. operating at Jimulco, says they will put up an aerial tramway for ore transportation from their mine to the railroad, a distance of 4 miles.

The Magafil C. Co. of Concepcion del Oro, Zacatecas, proposes huilding a lead smelting plant at Saltillo. Manager W. J. Browning, at Saltillo, says construction will hegin this spring.

The Mexican Coal & Coke Co., owning 20,000 acres of coal lands in Muzquiz district, 13 kilometers west from Barroteran, is producing 2000 metric tons of coal daily. The property is equipped with 226 coke ovens, the maximum capacity of the latter heing given as 7000 metric tons of coke per month. E. Ludlow is manager.

The Reforma mine, owned and operated hy the Jimulco M. Co., is 13 kilometers south from Jimulco station on the Mexican Central Railroad. Development consists of one two-compartment vertical shaft, down 260 feet, and of four tunnels, hesides crosscuts, drifts, etc., says the Mexican Investor. Tho ore carries gold, silver and copper values, and 1000 tons are produced monthly.

Colima.

M. de F. Reuix and J. W. Furness of Colima are preparing to open up and operate iron mines near Colima.

Durango.

(Special Correspondence).—Cushing & Walkup, owners of the Trinadad mine, have on hand large amount of matte ready for shipment. This mine is in Topia district in western Durango. The ore carries high-grade gold, silver and copper values.

R. C. Kirk of San Francisco, Cal., is starting up work on his mine at Puehhito, near Vivovillas. The ore is free-milling geld and silver.

Work is being done on the mines of D. M. Burns at San Dimas. The property consists of several claims, the most productivo of which are the Candalaria, Contra Estaca and La Puerta. The Candalaria is a geld and silver claim and was worked by the Spaniards. Over 12,000 feet of work has been done in the main tunnels and shafts. The Contra Estaca carries gold and silver.

The Provedora mino is closed down pending sale to American partics. It is owned by Mazatlan and Guadalupe de los Reyes men. It is a gold and silver claim in Topia mining district, between the Elota and Barraganes rivers. A 10-stamp mill, operated by steam power, handles the ore, and concentrates are shipped to Mazatlan.

The mines at Mina de Vacas, in Mozquital district, are being worked by an American company. The ores are silver bearing, with values in lead and gold.——A streak of silver ore has been struck in the Carrizo mine, owned by J. Loya of Cosala.

Durango, Jan. 28.

C. B. Flynn of Parral, manager of the Maverick M. Co., operating in Avino camp, says development work is being increased. Some of the properties have been worked extensively, but most of them are now. The ores carry silver, gold and copper. The Avino district is 30 miles from Durango and 10 miles from the National Railroad. Water and timber are abundant.

L. F. Morris, manager of the Huahuapan M. Co. at Huahuapan, says they will put in additional machinery and other improvements te increase development.

The Restauradora M. Co., of Guanacevi, H. H. Hughes manager, is putting up a cyanido plant to treat 100 tons of ore daily. The amalgamation process has been used heretefore.

Guanajuato.

La Luz M. Co. of Colorado Springs, Colo., owning the Refugio and Santa Clara mines, near La Luz, proposes building an entirely new plant, to have capacity for treating 500 tons of ore per day and to be operated by electric power. There are three double-compartment vertical shafts, respectively 980, 600 and 700 feet in depth, with crosscuts, drifts, etc. The ore carries gold and silver values. The properties aggregate 280 acres. G. N. Bryant is manager.

A company has heen organized in Mexico City to take over and exploit the cinnahar properties of de Rilly (the Las Palmas y Annexas), in San Felipe district. P. de Rilly is manager, and has started operations. It is claimed three lodes show assays of 3% quicksilver from the outcrop.

Hidalgo.

J. M. Erskine says ho will build a stamp mill at his mines near Ahuechuetes.——P. J. Howard and S. Farrol, operating near Pachuca, propose to put in additional machinery.

San Luis Potosi.

The Santa Maria de la Paz mine, consisting of 179 pertenencias, in Catorce district, 6 kilometers northwest from Matehuala, owned and operated hy the Negociacion Santa Maria de la Paz of Matehuala, is being developed through thirteen shafts, eleveu levels and various crosscuts, drifts, etc. The maximum depth attained is 1600 feet, while some of tho workings are over 6000 feet in length. There are said to he eight lodes cutting the property, the ore carrying gold, silver and lead. The equipmeut consists of six double steam hoists, six pumps, five engines, fourteon hoilers, two electric generators for lighting the minc, camp, etc., air compressors and concentrators. Ore and concentrates are shipped to the smelters in the vicinity.

Sinaloa.

(Special Correspondence). — Minney, Garvin & Boland of Los Angeles, Cal., are working tho Trinadad mine, west of Guadalupe de los Reyes. The ore is free-milling gold, with small values in silver appearing as depth is gained. The vein mattor is decomposed quartz and lime. They are testing the ores with Huntington mill with daily capacity of eight tons. The mill is operated by water wheel, water being obtained from the Elota river. The mill is 6 miles from the mine, the ores being packed hy burros at cost of $5.75 per ton, Mexican money.——G. Cunningham has resumed work at tho Barrateros mine, 6 miles north of Cosala. It was an antigua carrying high silver values.

Guadalupe, Jan. 26.

A 10-stamp mill is being built hy the Lluvia de Oro M. Co. at its mines at Choix.

Sonora.

(Special Correspondence).—A new single-compartment shaft has heen started on La Gloria mine of La Dura M. & M. Co., and is down 75 feet. A double-deck

cage will he put in. The shaft will be sunk to 500 feet. They are hoisting with buckets aud small air hoist until larger plant can be set up. At La Prieta mine, belonging to same company, the double-compartment shaft is down 1020 feet. From this level a crosscut of 900 feet is being run, of which they have already driven 300 feet. P. Schabarum is superintendent and A. S. Graff assistant superintendent.

The Golfo del Oro M. Co., near the Yaqui river, is working forty men, and lately made a 50-ton shipment to the Yaqui S. & R. Co. at Toledo, 10 miles from the mines, with satisfactory results. E. T. Page is superintendent.

La Dura, Jan. 30.

J. E. McIntyre, chemist for the Ruby G. & C. Co., operating at Batamote, says the company has a large quantity of ore ready for reduction, and is hauling fluxes, fuel, etc., preparing to start the reduction works. G. W. Crowe is manager.

The mill of the Cerro Prieto mines at Cerro Prieto, in Magdalena district, owned by C. N. Thomas et al. of Chicago, Ill., will be increased from 20 stamps to 120 stamps, says the Bisbee Review. The Caliche Mountain M. Co., consisting of Tener Bros. and others, is working a property 12 miles from Cerro Prieto on which are three ledges, 5 to 8 feet wide, carrying $12 per ton in gold.

H. K. Chenoweth of Nogales, Ariz., interested in El Dormido mine, near the Cerro Prieto mines, in Magdalena district, reports a strike of high-grade gold ore on El Dormido.

J. L. Sheperd of Nogales, Ariz., president of the Trimetallic M., S. & R. Co., says he will increase development work on the company's mines in Sonora.

Twelve miles east of Magdalena, J. J. Sullivan is working the Calabasas placer grounds and reports progress.

The Cinco Senores mine at Picacho, near Douglas, Ariz., is reported sold to Detroit, Mich., men. This group of claims is an extension of the Picacho mine of Phelps, Dodge & Co.

Tamaulipas.

The Mexican Petroleum Co. is building an oil refinery at Ebano to have capacity of 800 barrels daily. Other improvements will also be made, including a railroad, on which work is under way, 6 miles long, between the refinery and the oil fields.

Zacatecas.

The San Luis del Oro mine, consisting of 88 pertenencias, 2 kilometers south from Zacatecas, owned and operated by the San Luis del Oro M. Co., is being developed through four shafts, the depths being, respectively, 220, 150, 130 and 150 feet. The equipment consists of a 20-stamp mill, 1000 pounds per stamp, two double steam hoists, one pump, two engines, four boilers and a fifty-ton cyanide plant. The plant, while not running at present, will be started up this month. Development work is progressing and ore is being stored.

The London Exploration Co. has bought the Guanatillo mine for $100,000 gold. The mine is near Ojo Caliente and consists of eight pertenencias. It is a silver producer.

VENEZUELA.

Caracas reports say the Federal High Court has handed down a decision in the asphalt case. The court gives judgment that the claim of Warner & Quinlan of Syracuse, N. Y., to possession of the Felicidad asphalt mine, a portion of the asphalt lake in the State of Bermudez, claimed also by the New York & Bermudez Asphalt Co., who hold a concession to work the lake, is null and void. The Felicidad mine was bought in 1898 by Warner & Quinlan. The court bases its opinion on the argument that, while the concession of the Bermudez Co. was valid, no claim to the Felicidad could he granted, and that Warner & Quinlan had bought the Felicidad mine without receiving proper title from the vendors.

Trade Treatises.

Queen & Co., Inc., 1010 Chestnut street, Philadelphia, 59 Fifth avenue, New York, "Fifty years, 1853–1903," make fine showing of their engineering and scientific instruments in their catalogue, which they will send to any desired address.

The 1904 catalogue of the Frue Vanuer from Jas. S. Brownell, the Western manager, 132 Market street, San Francisco, Cal., gives a historical sketch and description of the machine, describes also its method of working, discusses in detail the requirements connected therewith, with practical information, and illustrations regarding the entire suhject of ore concentration, of general interest to millmen.

Personal.

J. N. KELLY of Bodie, Cal., is in San Francisco, Cal., on mining business.

H. S. WOOLLEY has been reappointed assayer of the mint at Boise, Idaho.

J. DRYSDALE, owning mines near Calgary, Alberta, Canada, is in San Francisco, Cal.

J. BENDER of Hamilton, Ohio, interested in California mines, is in San Francisco, Cal.

J. E. MCINTYRE is chemist for the Ruby G. & C. Co., operating at Batamote, Sonora, Mexico.

R. HAYES BARNES is in charge of the Black Hawk mine for Los Angeles parties, Soulsbyville, Cal.

H. K. WHEELER has returned to Los Angeles, Cal., from inspection of iron deposits on the Mojave desert.

H. S. SIMMONS of New York City, interested in Nevada mines, is in San Francisco, Cal., on mining business.

E. LEVY is assistant manager of the Le Roi Two C. Co. at Rossland, B. C., going there from Denver, Colo.

G. SNYDER of Salt Lake City, Utah, of the Western Exploration Co., is in San Francisco, Cal., on mining business.

LAFAYETTE DURKEE, inventor of the Durkee electric drill, has gone south for the winter on account of his health.

I. W. BARNETT, interested in mines of Chile, South America, is in San Francisco, Cal., from Antofagasta, Chile.

C. C. TYLER, interested in Borneo oil fields, is in San Francisco, Cal., from Koetei, Borneo, en route to London, England.

T. G. HAILEY of Pendleton, Or., is president of the Golconda M. Co., operating near Sumpter, Or., vice C. B. Wade, resigned.

F. L. BOSQUI of Mill Valley (Eastland P. O.), Cal., is in Goldfield, Esmeralda county, Nev., making ore tests for cyanide treatment.

J. H. HOPPER, C. E., has returned from San Francisco, Cal., to Sonora, Tuolumne county, Cal., where he has mining interests.

C. J. ALFORD of London, Eng., is in Egypt, visiting the Um Rus, Fatira and Eridia mines of the Egyptian Mines Exploration Co., Ltd.

W. L. WATTS, E. M., of Los Angeles, Cal., is making mine examinations in the State of Mexico, Mex., and in the surrounding territory.

B. MOODY is superintendent of the California King G. M. Co. and is at the mines at Picacho, San Diego county, Cal., from the Black Hills, S. D.

W. E. DEFTY of Phœnix, Ariz., manager of the Arizona-Mexican C. Co., is in Sonora, Mexico, with a party of Eastern men, examining mines.

R. ECKMAN, former superintendent of the Columbia mine, is superintendent of the Midway mine, near Sumpter, Or., vice S. G. Williams, deceased.

G. W. ROOT, manager of the New York-Grass Valley Con. M. Co., returned last week to Grass Valley, Cal., from a business trip to New York.

J. BELL, of French Gulch, Shasta county, Cal., accompanied M. J. Lidstone of San Francisco, Cal., to Dale, Cal., to engage in mill construction.

G. W. MYERS, representing the Chrome Steel Works of Brooklyn, N. Y., has returned to San Francisco, Cal., from Arizona and southern California.

EDMUND JUESSEN of Spokane, Wash., is manager of the Franklin mine, 48 miles north of Mountain Home, Idaho, owned by R. P. Chatin & Co. of Spokane, Wash.

J. G. HARDY, formerly superintendent of the Creston-Colorada M. Co. at La Colorada, Sonora, Mexico, is with the Dolores M. Co. at Minaca, Chihuahua, Mexico.

J. AND G. RICH AND G. ERICKSON returned to Rossland, B. C., last week from the Ketchikan district, Alaska, where they have been engaged in mining for the past nine months.

WM. SCALLON of Butte, Mont., has resigned as president of the Anaconda C. Co. and manager of the Amalgamated C. Co. properties in Montana, due to pressure of private affairs.

L. E. TOMBLIN, superintendent of the Bear Gulch M. Co., operating near Deadwood, South Dakota, has gone to Alabama for same company to inspect newly developed gold fields in that State.

C. PREUSSE has retired from the firm of Preusse, Swoyer & Van Dreveldt, at Parral, Chihuahua, Mexico, and taken position as consulting engineer of a company in Tlalpujahua, Michoacan, Mexico.

T. H. BAILEY WHIPPLE has returned to the Sawyer-Man Electric Co. to the position he left last summer in order to take part in the reorganization of the sales department of the Nernst Lamp Co. of Pittsburg.

PROF. F. E. FIELDING, for thirty years chemist for Mackay & Fair, Virginia City, Nev., has resigned, and, in connection with his half-brother, H. K. Wheeler, will have charge of a Los Angeles, Cal., laboratory that they have bought.

Obituary.

W. SEBASTIAN, a pioneer miner of French Gulch, Shasta county, Cal., died Jan. 21st at French Gulch. Deceased formerly owned the Brown Bear quartz mine in Trinity county. He was aged 76 years.

W. P. MCCULLOUGH, a pioneer miner of southern California and Arizona, was killed by a Santa Fe train near San Bernardino, Cal., on the 2nd inst. Deceased was one of the original locators of the Calico mines, large producers of silver in the eighties.

W. R. THOMAS, a mining man of Nevada City, Cal., died Jan. 22d of miner's consumption. Deceased went to California from Cornwall, Eng., during the Civil War and engaged in mining in Sierra county and in Nevada county. He is survived by a widow, two sons and two daughters.

N. GREEN, a pioneer miner of Colorado and Arizona, died at Solomonville, Ariz., Jan. 18th. Deceased was born in Johnstown, Illinois, July, 1821. In 1880 he settled in Colorado and for several years engaged in mining in Silverton district, San Juan county; and in 1886 moved to Solomonville, Arizona.

T. ROSEVEAR, a pioneer miner of Nevada, died at Ruby Hill, Eureka county, Nev., Jan. 18, of miners' consumption. Deceased was a native of Cornwall, England, aged 49 years. He went to Eureka from Missouri in 1878, and followed mining on Ruby Hill for a quarter century. He is survived by a wife and eight children.

S. G. WILLIAMS, superintendent of the Midway mine, near Sumpter, Or., died at Hot Lake, Or., Jan. 19th, after a brief illness. He leaves a wife and one daughter. Deceased, as a superintendent in the Sumpter district, had had charge of the Bonanza and also of the Gem mines. In his younger days he was a cattle inspector in Texas and New Mexico, and an Indian scout.

BENJAMIN PICKARD, president of the Miners' Federation of Great Britain and Liberal member of Parliament for Normanton, Southwest Riding, since 1885, died on the 3rd inst. of heart disease, aged 62 years. Deceased was instrumental in securing the mines acts, the employers' liability acts, the miners' eight-hour bill and other laws relating to protection of employes.

G. D. DAVEY, formerly a mining superintendent of Michigan and of Colorado, died at Grass Valley, Cal., Jan. 23d from miner's consumption. Deceased was a native of Devonshire, Eng., and at age of nineteen went to Michigan. Later, in Colorado, he was superintendent of a copper mine for a few years. Twenty-five years ago he went to Grass Valley, and with exception of two years spent at Virginia City, Nev., has heen connected with Nevada county mines. He leaves a wife and two daughters.

HENRY CABLE, a pioneer mining man of Sumpter district, Oregon, died at San Jose, Cal., Jan. 20th, aged 52 years. Deceased was one of seven hrothers who went to Oregon when young men, engaging in mining with their father. They located the Monumental mine, and operated placers on Granite creek. Later they became interested in Cable Cove properties. In 1887, deceased located the Columbia mine on Cracker creek, and later the Climax, and Cracker-Oregon.

Dividends.

Bunker Hill & Sullivan M. & C. Co., Idaho, $33,000; payable Feh. 5.

Commercial Paragraphs.

THE George E. Dow Co. of San Francisco, Cal., will place a three-triple compound pump of 300,000 gallons daily capacity in the Halifax mine, Tonopah, Nev., at the bottom of the 700-foot shaft.

THE Denver hranch of the Jeanesville Iron Works Co. recently sold the Camp Bird mine two electric power pumps, 1000-foot lift, which will be the highest electric lift in the State; also a steam pump, 600 gallons capacity, to Victor, Colo.

THE Onderdonk Engineering Co., C. S Onderdonk president, E. H. Wells vice president and J. G. Ward secretary and treasurer, have opened an office and show room at 1421–23–25 Fifteenth street, Denver, Colo., where they intend to carry a line of Babcock & Wilcox water tube boilers, Keasby & Mattison Co.'s magnesia coverings, Goubert Mfg. Co. heaters, Foster Engineering Co. regulators and other specialties.

THE E. I. Dupont de Nemours Powder Co. of Delaware, New York and Pennsylvania is credited with present intent to go extensively into the manufacture of mine explosives, including giant powder, etc., on the Pacific Coast in competition for a part of the extensive trade therein, the idea being to build a large factory therefor on the shores of San Pablo bay, near San Francisco, Cal. It is estimated that upward of 35,000,000 pounds of dynamite and 200,000 kegs of black powder were used in the territory subsidiary to San Francisco in 1903, and that the profitable nature of the business warrants active competition. Whether such promised competition will result in reduced prices to consumers remains to be seen.

THE Power & Mining Machinery Co. have a contract with the Elmira, N. Y., Water, Light & Railroad Co. for a four-cylinder American Crossley gas engine of the opposed type, with cylinders 32 inches in diameter by 36 inch-stroke, to run 138 revolutions per minute and to develop, under normal load, 1300-brake H. P. with natural gas containing 1000 B. T. U. per cubic foot. This engine will be direct coupled to a General Electric sixty-cycle alternator of the fly-wheel type, and will run in parallel with their existing steam engines and with such other gas engines as they may install in the future. This engine will be used for both lighting and power; the direct current for their railway work secured by the use of rotary converters; also with the Milford, N. H., Electric Light Co. for one 80-brake H. P. high-speed Crossley gas engine with cylinders 17x24 inches, and one Crossley suction-type producer plant of the same capacity. The Motor Engine Co., 15 William street, New York City, one 20-brake H. P. Crossley new type suction gas producer, to be installed at their Staten Island shops. The Amparo Mining Co., Philadelphia, Pa., one 190-brake H. P. Crossley high-speed double-cylinder gas engine, with cylinders 18½x24 inches; and two high-speed single-cylinder Crossley gas engines of 130-brake H. P. each, with cylinders 20x30 inches; six 9x15 foot Loomis generators, with two 10,000 cubic foot holders. This contract also includes mining machinery, consisting of crushers, Bruckner roasting furnaces, condensing chambers, etc. International Steam Pump Co., New York City, for installation at their new plant at Harrison, N. J., two 11x16 foot Loomis-Pettihone gas generators, together with two 10,000 cubic foot holders. This plant is to be used for metallurgical work about the new Harrison plant. Nogales Copper Co., Chicago, Ill., for installation in Mexico, three Crossley high-speed double-cylinder gas engines, 330-brake H. P. each, with cylinders 25x30 inches; and one Crossley high-speed single-cylinder gas engine, with cylinder 18½ x27 inches; four 9x15 foot Loomis-Pettihone gas generators, one 10,000 cubic foot holder and one 5000 cubic foot holder. This contract also includes the mining machinery for the plant. Sayles' Bleacheries, Saylesville, R. I., one 255-brake H. P. two-cylinder 22x30-inch high-speed gas engine. At this plant the water gas, generated hy the Loomis-Pettibone system, built by us, is in use for heating the singeing machinery, and the producer gas in the gas engines. The new engine is to run in parallel with another gas engine which has been running at the Sayles' Bleacheries for over a year.

THE Gihhs Engineering & Manufacturing Co. of Glendale, Long Island, N. Y., recently gave private exhihitious of a new type of tractor-drawn road train which has just been completed for the Death Valley Borax Co. of southern California. The train consisted of a tractor carrying the gasoline engine and generator (which comprises the generating set) and two

trail cars for carrying the desired load. The current generated on the tractor is distributed through a controller to motors on the drive wheels of the tractor and the trail cars. In this way each unit of the train is said to be practically self-propelling. The trail cars, each of which is of ten tons carrying capacity, are chain-driven, instead of being geared. As each car is virtually an independent unit, the tractor itself is of light construction, and the company claims, along with the advantages of special features of construction, that a large increase of paying load is possible. The test mentioned was carried out under adverse conditions, on a considerable grade covered with snow and ice. The test was witnessed by a distinguished party of expert engineers and automobilists, who later adjourned to the firm's new factory to inspect a five-ton truck of the Gibbs type, with five tons carrying capacity, that was being completed for exhibit at the annual automobile show at Madison Square Garden, New York. After luncheon, which was served at the factory, congratulatory speeches were made by Henry Norman, M. P., editor of the World's Work, who recently arrived on a visit to this country; C. E. Pickett, superintendent of the Death Valley Borax Co.; W. E. Scarritt, president of the Automobile Club of America; Dr. A. R. Ledoux, the well-known chemical expert and mining engineer, and others.

Latest Market Reports.

SAN FRANCISCO, February 5, 1904.

METALS.

SILVER.—Per oz., Troy: London, 25⅝d (standard ounce, 925 fine); New York, bar silver, 55⅜c, refined (1000 fine): San Francisco, 55½c; Mexican dollars, 43@44c San Francisco, 42½c New York.

COPPER. — New York: Standard, $12.62½; Lake, 1 to 3 casks, $12.62½; Electrolytic, 1 to 3 casks, $12.50; Casting, 1 to 3 casks, $12.22½; San Francisco: $15.00. Mill copper plates, $17.00; bars, 18@24c. London: £56 10s spot per ton.

Copper shows little change from last week's quotations, being a fraction lower than a week ago. James Lewis & Sons' annual copper report says that the most prominent feature of the copper trade in 1903 was the reduction in public and private stocks in England. This indicates that these stocks were drawn upon and not replenished, and that the stocks are now low, and that a buying movement must soon commence, which will have a tendency to raise the price with a resultant stimulus to increased production.

LEAD. — New York, $4.45; Salt Lake City, $3.50; St. Louis, $4.25 San Francisco, $4.50, carload lots; ⅛c 1000 to 4000 lbs.; pipe 6½, sheet 7, bar 5½c; pig, $4.85. London: £11 2s 6d ℔ long ton.

SPELTER.—New York, $5.00; St. Louis, $5.00; London, £21 15s ℔ ton; San Francisco, ton lots, 6¾c; 100-lb. lots, 7c.

TIN.—New York, pig, $27.50 @ 28.00; San Francisco, ton lots, 30½c; 500 lbs., 31c; 200 lbs., 31½c; less, 32½c; bar tin, ℔ lb., 35@37½c. London, £126 2s 6d spot.

PLATINUM. — San Francisco, crude, $18.00 ℔ oz.; New York, ingot, $19.00 ℔ Troy oz. Platinum ware, 75 @ 82c ℔ gram.

QUICKSILVER. — New York, $46.50@47.00, large lots; London, £8 7s 6d; San Francisco, local, $44@45 ℔ flask of 76½ lbs.; Denver, $48.00. Export, $42.00@42.50.

BABBITT METAL.—San Francisco, No. 1, 10c; No. 2, 7c; No. 3, 6½c; extra, 17½c; genuine, 31½c; Eclipse, 35c.

SOLDER. — Half-and-half, 100-lb. lots, 19.50c; San Francisco, Plumbers', 100-lb. lots, 16.50c.

ZINC.—Metallic, chemically pure, ℔ lb., 50c; dust, ℔ lb., 10c; sulpbate, ℔ lb., .04c.

NICKEL.—New York, 50@60c ℔ lb.; ton lots, 40@47c.

ALUMINUM.—New York, No. 1, 99% pure ingots, 35c; No. 2, 90%, 30@34c.

LUMBER. — (Retail): Pine, ordinary sizes, $24.00@25.00; extra sizes bigber; redwood, $28.00@30.00; lath, 4 feet, $4.50 @5.00; pickets, $21.00; sbingles, $2.50 for No. 1 and $2.25 for No. 2; sbakes, $13.50 for split and $15.00 for sawed; rustic, $28.00 @35.00.

NAILS.—This week the basic prices are: Wire, $2.77; Cut, $3.25. Meanwbile the nominal quotations per keg (list prices) are: No. 20d to 60d, Wire, $3.35; Cut, $3.55; 10d to 16d, Wire, $3.45; Cut, $3.35; 8d Wire, $3.50; Cut, $3.50; 6d and 7d, Wire, $3.60; Cut, $3.60; 4 and 5d, Wire, $3.70; Cut, $3.70; 3d, Wire, $3.85; Cut, $3.85; 2d, Wire, $4.10; Cut, $4.10. Special rates for carload lots.

LIME.—Santa Cruz, $1.25 country, $1.25 city ℔ bbl.

CEMENT.—Imported, $2.15@2.40 ℔ bbl.; California carload lots, $2.00 f. o. b. at works; small lots, $2.25 ℔ bbl. in sacks, 4 sacks to bbl.

STRUCTURAL MATERIALS.

IRON.—Pittsburg, Bessemer pig, $14.00 @14.25; gray forge, $13.00; San Francisco, bar, 3c ℔ lb., 3½c in small quantities.

STEEL. — Bessemer billets, Pittsburg, $23.00@23.50; open hearth billets, $23.00 @23.75; San Francisco, bar, 7c to 12c ℔ lb.

BONE ASH.—Extra No. 1, 5@6c ℔ lb. No. 1, 4@5c.

COAL. — San Francisco, coast, yard prices: Wellington, $8.00; Seattle, $6.50; Coos Bay, $5.50; Soutbfield, $8.00. Cargo lots, Eastern and foreign: Wallsend, $7.50; Brymbo, $7.50; Pennsylvania, bd., $14.00; Scotch, $8.00; Cumberland, $13.00; Cannel, $8.50; Welsh Antbracite, $13.00; Rock Springs, $11.50, long ton; Colorado Antbracite, $14.00. Coke, $10.50 per ton in bulk, $13.00 in sacks; Sunnyside, $11.50, long ton.

OILS.—Linseed, boiled, bbl., 49c; cs., 54c; raw, bbl., 47c; cs., 52c; Lucol oil boiled, bbl., 44c; cs., 49c; raw, bbl., 42c; cs., 47c. Kerosene—Pearl, per gal., 21½c; Astral, 21½c; Star, 21½c; Extra Star, 25½c; Eocene, 24½c; Elaine, 27½c; Water White, in bulk, 15c; Mineral Seal, iron bbls., 19c; wooden bbls., 21½c; cs., 25c; Mineral Sperm, cs., 26½c.; Deodorized Stove Gasoline, bulk, 17c; do., cs., 23½c; 86° Gasoline, bulk, 25c; do., cs., 31c; 83° Naphtha or Benzine, deodorized, in bulk, per gal., 13c; do., in cs., 19½c; Lard Oil, E W. S., bbl., 85c; cs., 90c; Neats-foot Oil, pure, bbl., 75c; cs., 80c; Sperm, crude, 60@65c; Natural Wbite, 70c; Bleacbed, do., 80c; Whale Oil, cs., 50@55c.

WHITE LEAD.—Per lb., in kegs: 500 lbs. and over at one purchase, per lb., 6½c; less tban 500 lbs., per lb., 7c; in 25-lb. tin pails, ¼c ℔ lb. above keg price; in 1 and 5-lb tin cans, 100 lbs. per case, ½c. per lb. above keg price. Dry Lead—In bbls., 1 ton and over, 6½c; do. in kegs, 7c.

RED LEAD.—500 lbs. and over at one purcbase, ℔ lb., 6½c; less tban 500 lbs., 7c.

LITHARGE.—Pure, in 25-lb. bags, 8@9c ℔ lb.

BORAX.—Concentrated, 6@7c ℔ lb; powdered, 8@10c; fused, 20@25c; crystal, 7c; calcined, 25c.

MANGANESE.—Pure, ℔ lb., 60c.

SODIUM.—Metal, ℔ lb., $1.00.

BISMUTH.—Subnitrate, ℔ lb., $1.75.

MERCURY.—Bicbloride, ℔ lb., 90c.

MOLYBDENUM.—$2.00 ℔ lb.

CHROMIUM.—90% and over, ℔ lb., $1.00.

PHOSPHORUS.—American, ℔ lb., 75c.

SILVER.—Chloride, ℔ oz., 90c@$1.00; nitrate, 55c.

ALUMINUM.—No. 1., 99%, small lots, 37c ℔ lb.; 100 lbs., 35c; 1000 lbs, 34c; ton lots and over, 33c, Pittsburg. No. 2, 90%, small lots, 34c; ton lots and over, 31c, Pittsburg.

URANIUM.—Oxide, ℔ lb., $3.50.

(Tbese prices are wbolesale, f. o. b. San Francisco, unless otberwise noted.)

New Patents.

DEWEY, STRONG & CO.'S SCIENTIFIC PRESS PATENT AGENCY, 330 Market St., S. F., has official reports of the following U. S. patents issued to Pacific Coast inventors:

FOR THE WEEK ENDING JAN. 26, 1904.

750,420.—SASH FASTENER—J. Anderson, Seattle, Wash.

750,518.—PRESERVING APPARATUS—C. Blagharn, S. F.

750,584.—ELECTRICAL VIBRATIONS—F. H. Brown, Los Angeles, Cal.

750,588.—KILN—H. M. Buck, Burlington, Wash.

750,257.—CLOSURE—E. E. Chapman, Los Angeles, Cal.

750,259.—WEIGHING MACHINE—W. H. Coffelt, Anacortes, Wash.

750,263.—FELLY JOINT—W. J. Cranford, Spokane, Wash.

750,430.—LABEL HOLDER—L. C. DeCarli, San Jose, Cal.

750,443.—GLOVE—F. W. Farrant, S. F.

750,628.—FRUIT FEEDER—I. H. Fay, Iadlo, Cal.

750,444.—PIPE COUPLING—P. E. Fisher, Spokane, Wash.

750,760.—CAN FILLING MACHINE—F. B. Fulton, Anacortes, Wash.

750,450.—FAN—O. Giltner, Portland, Or.

750,276.—VAGINAL SYRINGE—F. J. Gruss, S. F.

750,364.—NUT LOCK—F. A. Howard, Fresno, Cal.

750,284.—COMBINATION TOOL—J. Jenkins, Buckley, Wash.

750,054.—JAR HOLDER—Kate A. Johnson, Lorene, Wash.

750,286.—WATER TUBE BOILER—T. W. Johnson, S. F.

750,674.—GAS GENERATOR—W. S. May, Clifton, Ariz.

750,480.—BICYCLES—J. McLarty, Seattle, Wash.

750,677.—GOPHER TRAP—J. Morawetz, Castella, Cal.

750,490.—RAILWAY RAIL JOINT—C. L. Pope, Ely, Nev.

750,706.—CONCENTRATOR—H. J. Russell, Crescent Mills, Cal.

750,733.—TROLLEY POLE—J. J. Tartt, Los Angeles, Cal.

36,747.—DESIGN—FINGER RING—H. S. Dana, S. F.

Notices of Recent Patents.

Among the patents recently obtained through Dewey, Strong & Co.'s SCIENTIFIC PRESS U. S. and Foreign Patent Agency, the following are worthy of special mention:

LABEL HOLDER FOR LIBRARY SHELVES.—No. 750,436. Jan. 26, 1904. L. C. De Carli, San Jose, Cal. This invention relates to a device for holding labels and means for attaching it to library shelves, so that the subjects treated by the books contained on the shelves may be indicated to those desiring to use them. It consists of a slip or label holder having a curved segment extending rearwardly therefrom, said segment being recurved upon itself and adapted to fit upon a correspondingly shaped segmental curve of the front of the shelf or a guide which may be fixed to the shelf.

RAILWAY RAIL JOINT.—No. 750,490. Jan. 26, 1904. C. L. Pope, Ely, Nev. The object of this invention is to provide a labor and time saving means for joining abutting ends of rails in a rigid bond without the use of the usual fish plates and bolts and to provide a smooth durable joint over which car trucks may pass in either direction without a jar irrespective of the expansion or contraction of the rails. In this construction one rail holds the other and a rail can only be taken out by removing the spikes and lifting both rails.

GLOVES.—No. 750,443. Jan. 26, 1904. F. W. Farrant, San Francisco, Cal. This invention relates particularly to that class of gloves which is used for driving, handling metals and for like services; and the object of the invention is to so dispose the seams as to get them out of the way of wear as much as possible. This is accomplished by an ingenious method of cutting and securely and neatly fastening the seams.

FINGER RING.—No. 36,747. Jan. 26, 1904. H. S. Dana, San Francisco, Cal. This invention is an ornamental design for a finger ring.

SITUATIONS WANTED.

ASSAYER WISHES POSITION: HAS OUTFIT, if necessary. Address "L.," this office.

A YOUNG MINING ENGINEER DESIRES position as assistant; assayer and good draughtsman; State licensed surveyor for California. Address C. R., care Min. and Scientific Press.

EXPERIENCED SUPERINTENDENT, ENGINEER, Metallurgist; technically and liberally educated; 15 years handling men and machinery of smelters, mills and mines. See testimonials. Address Prof. Stickney, Mountain View, Cal.

MILL AND SMELTER SUPERINTENDENT, at present disengaged, wishes similar position with responsible company; college graduate with varied experience. Best of credentials furnished and required. Address "Gluckauf," care this office

MILL FOREMAN WANTS POSITION; 20 years' experience; good references; correspondence solicited. Address Mill Foreman, 1056 South Gaylord St., Denver, Colo.

MINING ENGINEER AND METALLURGIST, technical graduate, with large experience as superintendent, manager and consulting engineer of mines and mills, desires a position. Best references. Speaks Spanish fluently. Address "Ingeniero," care of Mining and Scientific Press.

SUPERINTENDENT IS OPEN FOR POSITION to develop gold or copper properties; experienced miner; can make underground maps and models, also do the assaying; speaks Spanish; good references from past companies. Address "Develop," care this office.

WANTED—POSITION WITH MINING COMpany as manager or assistant. Examinations, surveying, assaying; also familiar with drift and hydraulic mining. Best of references. Address W. H. J., this office.

WANTED—POSITION AS SUPERINTENDENT or assistant of copper mines and smelters; competent all round man, good assayer, analyst and draughtsman; can handle labor; speaks Spanish. Address "Smelter," care this office.

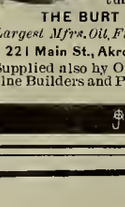
YOUNG GRADUATE OF GOOD MINING school wants position with reliable mining company. Not afraid of hard work. Object, advancement. Address "Advancement," care of this office.

HELP WANTED.

WANTED—MINE SUPERINTENDENT OF EXperience, who thoroughly understands handling of gold-bearing ores and management of mine and men. Must be willing to take part of salary in stock of company until mine is on paying basis. Mine is in California. Only thoroughly competent men need apply. References required and given. Address G. Mines, care of Mining and Scientific Press, San Francisco, Cal.

TEST THE
CROSS OIL FILTER
FOR YOURSELF.

The Russell Engine Co. says of the CROSS OIL FILTER: "It reduces the loss in oil to a minimum."



We guarantee the CROSS OIL FILTER TO SAVE 50% OF YOUR OIL MONEY.

Test it for yourself. We will send the CROSS OIL FILTER on thirty days' trial. If unsatisfactory, return at our expense.

THE BURT MFG. CO.,
Largest Mfrs. Oil Filters in the World,
221 Main St., Akron, Ohio, U. S. A.

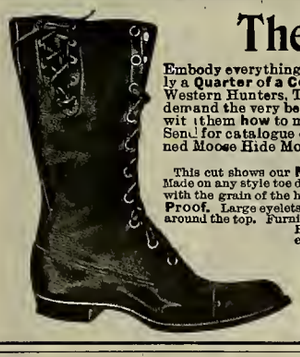
Supplied also by Oil Companies, Engine Builders and Power Contractors.

"Who has the right time?"
The man who has
ELGIN
TIME
every time

Every Elgin Watch is fully guaranteed. All jewelers have Elgin Watches. "Timemakers and Timekeepers," an illustrated history of the watch, sent free upon request to

ELGIN NATIONAL WATCH CO., ELGIN, ILL.

CLAM-SHELL DREDGES AND
CAST STEEL CLAM-SHELL BUCKETS
OUR SPECIALTIES.
STOCKTON IRON WORKS, STOCKTON, CAL.



The Putman Boots

Embody everything that is practical in Sportsmen's Footwear. For nearly a **Quarter of a Century** Putman Boots have been the standard among Western Hunters, Trappers, Prospectors, Ranchmen and Engineers (who demand the very best) and we have learned through our personal contact with them **how** to make a perfect boot. Putman Boots are **water proof.** Send for catalogue of over 20 different styles of boots. Also Indian Tanned Moose Hide Moccasins.

This cut shows our **No. 678** Three Quarter Boot, (14 inches high) Bellows Tongue, Made on any style toe desired. Uppers are Special Chrome Tanned Calf Skin, tanned with the grain of the hide left on (our special tannage) making the leather **Water Proof.** Large eyelets and wide leather laces, also laced at side to fit the boot tight around the top. Furnished in Black, Brown or Straw Color. Sole, Light, Medium or Heavy. The sole is genuine Hand Sewed (making it soft and easy), and made of the best Water Proofed Oak Sole Leather.
Made to your measure and delivered to any part of the U. S. for **$7.50**
Send for order blank showing how to measure your foot.

H. J. PUTMAN & CO.
23 BRIDGE SQUARE. MINNEAPOLIS, MINN.

Riveted Iron and Steel Pipe

FOR HYDRAULIC MINES, IRRIGATION AND POWER PLANTS. Manufactured from the best grades of IRON or STEEL by MODERN MACHINERY.

THE SCHAW-BATCHER COMPANY PIPE WORKS,
539 MISSION STREET, San Francisco. 211 to 219 J STREET, Sacramento.

SMOOTH-ON
TRADE MARK

Makes permanent repairs on Engines, Boilers, Pumps, Etc. Thousands of dollars saved by its use. Unequaled for stopping leaks of any kind. Send for catalogue M. S.

Sole proprietors and manufacturers, SMOOTH-ON MFG. CO., Jersey City, N. J.
For Sale by THE WESTERN REPAIR & SUPPLY CO.
40-42 East St. and 61-63 Steuart St., SAN FRANCISCO, CAL.

THE STANDARD ROOFING OF THE WORLD

RUBEROID
TRADE MARK REGISTERED

RUBEROID ROOFING is not made on the Pacific coast. We have no connection with any manufacturing corporation on the Pacific coast. We alone manufacture RUBEROID ROOFING. All statements to the contrary are false.

After twelve years of demonstrated superiority, Ruberoid Roofing is to-day without an Equal.

MANUFACTURED SOLELY BY
THE STANDARD PAINT COMPANY
100 WILLIAM ST., N. Y.

Sold in San Francisco by
BONESTELL, RICHARDSON & CO.
401-403 Sansome St.

Improved Gold Dredge

DESIGNED AND MANUFACTURED BY
THE BUCYRUS COMPANY, SOUTH MILWAUKEE, WISCONSIN.
The Western Engineering & Construction Company,
PACIFIC COAST REPRESENTATIVES, 408-414 RIALTO BUILDING, SAN FRANCISCO, CAL.

THE MARION STEAM SHOVEL CO.,
No. 644 W. Center Street, MARION, OHIO, U. S. A.

Steam Shovels,
Traction Dredges,
Dipper and Clam-Shell Dredges,
Suitable for all kinds of **Excavating Work,** also **Digging Ditches, Leveeing, Canal Construction, etc.,** making a specialty of
PLACER MINING MACHINES,
separate or self-contained, either as a **dry land** excavator or **floating dredge.**
We make our own Steel and Grey Iron Castings also our own Chain.

GEO. W. BARNHART, Western Manager,
No. 4 Sutter St., SAN FRANCISCO, CAL.

Our Catalogue No. 1 describes **WATER WELL MACHINES** of many sizes, both traction and non-traction, for wells 50 to 1000 feet deep, and gives full illustrated instructions for operating.
Catalogue No. 2 describes **MINERAL PROSPECTING MACHINES** for exploring for Iron, Lead, Zinc, Coal and all minerals. Several sizes, both traction and non-traction. Also **PLACER GOLD TESTING MACHINES** for assaying Alluvial Deposits, Lake and River Beds to bedrock. Can be used on boat.
Also Sectionalized Machines and Boilers for easy transportation to difficult places. They make 6 and 8-inch holes through anything and bring to the surface everything found. Full instructions for operating.
Catalogue No. 3 describes **OIL WELL MACHINERY** for wells 1000 feet to 2500 feet deep. Several sizes, with full equipment and instructions for operating.
Our Machines are the sum of all excellence, in use all over the world. Top quality, bottom prices. Catalogues FREE.

KEYSTONE DRILLER CO., BOX 90, BEAVER FALLS, PA., U. S. A.

MINING AND SCIENTIFIC PRESS.

Whole No. 2273.—VOLUME LXXXVIII. Number 7. SAN FRANCISCO, CAL., SATURDAY, FEBRUARY 13, 1904. THREE DOLLARS PER ANNUM. Single Copies, Ten Cents.

A Great Gold Mine.

One of the largest and most productive gold mines in the world is the Homestake property, at Lead City, South Dakota. The original location was called the Homestake, and was taken up in 1876, and is depicted in the left portion of the accompanying engraving, covering a part of what is now the great open cut. At that date quartz locations in the Black Hills were limited to a length of 1500 feet and a width of 300 feet. The open cut is more than 600 feet long and nearly 400 feet wide. The point of view from which the photograph was taken is the Ellison hoist. Originally there were two shafts on the Homestake proper, one of them an incline. Both were in the region of the cut. The lower one, however, shows at the extreme left. The first large vertical shaft was the Giant and Old Abe. The hoist building is seen in the middle background on the hillside. This shaft was sunk to a depth of 800 feet, where it remained for years. The Ellison shaft is the newest and largest on the property. The first mill built by the Homestake Company was one of 80 stamps, since enlarged. It is at the left of the picture, beyond the superintendent's residence. The next mill erected was the Golden Star, appearing in the center of the illustration, being connected with the Ellison shaft by steel tramway. The Amicus mill is situated to the right of the Golden Star. On the hillside back of these mills and between them are the foundry and machine shops.

The strike of the great gold-bearing zone is west of north, and corresponds nearly to a line drawn from the extreme left of the picture toward the observer. The dip is to the right (easterly) at variable angle, and the trend of the ore bodies is southward toward the observer. The higher hills are intrusive rocks (rhyolite) with some of the quartzites and shales of the Cambrian. The older formation, that in which the ore bodies occur, is Algonkian, and here consists of micaceous and hornblende schists of fine grain and containing much silica. Large masses of quartz occur in segregated lenses and veins in the schists. Locally a conglomerate overlies the schists, and this to the eastward of the Homestake zone is gold bearing. These deposits were the first in place to be mined and crushed in the Black Hills. In the quartzites and shales overlying the conglomerates, occur the telluride ores, some of which are found in the vicinity of the Homestake. Wolframite also occurs in the quartzite. The timbers and wood used in the mines and at the mills are delivered by railroad at the top of the hill near the center of the engraving. Cord wood is sent down to the several mills and hoists by means of chutes, several of which are seen in the picture. The Highland, Deadwood-Terra, Caledonia, Father De Smet and many other mines of the group lie to the northward beyond the hills forming the skyline on the left, a distance of about a mile, while southward the company's property extends to Whitewood canyon, almost an equal distance. The cyanide plants are located at two places. The first and largest is down Gold Run beyond the right of the limits of the picture. The other is over a mile distant to the northward, at Gayville, a small village in Deadwood gulch. One of the most important considerations in mining at the Homestake is abundance of water. This the local drainage and the mines do not supply. Water ditches and pipe lines have been constructed from numerous more or less distant sources, bringing water to the mines and mills. In the aggregate, these amount to several hundred miles of ditches, flumes and pipe lines.

The latest acquisition to the water system is the Spearfish plant. The Spearfish is one of the largest streams in the Black Hills. The water is pumped from the stream to Lead City, the pumps raising the water several hundred feet, on the neighboring hills, whence it flows by gravity to the Homestake. Lead is a city of about 8000 population.

General View of Homestake Mills From the Ellison Hoist, Lead City, South Dakota. (See Page 111.)

WHILE certain industrial stocks have depreciated somewhat in valne, and the investing public has been a loser thereby, mining as an investment is attractiug eonstantly more atteutiou, and there is au inquiry for legitimate mining investment, both in mines themselves aud in mining stocks of the better class.

NO one is authorized anywhere at any time to colleet money for snbseriptions for this journal without being able to show due authority in present force, and any itinerant so attempting may be considered an impostor. Nor does this journal allow any of its representatives auywhere at any time to solicit or receeive money for any mention of any kind in its reading columns. It is its boast that during the forty-four years of its existence it never yet took a dollar to put anything in its reading columns—or keep anything out—but every ten years or so it is necessary to restate that any one offering for payment of any sort to make favorable mention of mines, machinery, etc., herein, may be set down as a fraud.

A SYSTEM of mine bookkeeping is a desirable and necessary adjunct to successfnl mine management, but it, like many other useful and valuable aids to the manager, may be carried to an extreme and, in the way of segregating accounts, reach a phase whieh makes it ridiculous. It is desirable to know the average cost of mining and treating one ton of ore, and to know where these costs are placed, as to labor, hoistiug, supplies eonsumed, timbering, transportation, milling, etc., but when it is carried to the extreme of showing how many whisk-brooms were nsed np in the mill, and how many lamp wicks were burned per ton of ore mined and treated, the limit of usefulness has undoubtedly been reached.

Safety Devices for Shafts.

The reeent accident at the Independence mine, at Victor, Colo., has resulted in a wide discnssion among mining men over safety appliances for cages and skips in shafts, both vertieal and inclined. Among the various devices suggested are chairs, not only at the collar of the shaft, bnt at a point above it which would made it possible to catch the eage immediately upon the breaking of the cable in a ease of over winding, and safety clutches, so arranged and so powerful, as to hold the cage in any event, at any point in the shaft should the cable break. Manager O'Neill of the California mine, at Leadville, Colo., has suggested the adoption of a safety device similar to that in use at the California mine, which is one of the best suggestions thns far made, and is similar in operation to the chairs ordinarily placed at landiugs in shafts, though operating automatically. This device consists of two pieces of steel bolted to both guides in each compartment where cages or skips are in use, or they may be bolted to upright beams placed for the purpose, on eaeh side of the shaft. These steel bars are about 2 feet long, and are securely bolted at the lower eud to the guides or the beams, bnt the upper ends are sprung outward, into the shaft, so that at the top they are about 3 inches from the guides. In passing npward the shoes of the cage pass over the steel bars which beud inward, against the guides, sinking into a depressiou eut to receeive them, but in the event of overwinding, and the lower end of the shoes passing above these automatic chairs, the latter immediately spriug ontward, preventing the cage from deseending. Should the eable break, the cage will be held by the chairs.

If the eugine is stopped in time the cage may be lowered by drawing the spring chairs against the guides by means of a bolt welded to the bar, which passes loosely through a hole bored in the guide, and which is provided with a thread and nut at the opposite end. By turning up the nut the bar is drawn backward, releasing the cage. The position of this deviee mnst be sueh that only a limited space intervenes betweeu the top of the cage and sheave wheel after the bottom of the shoes passes the spriug chairs, so that shonld the eable break, the cage would drop ouly a few inches. A device of this or similar character shonld be provided at every shaft employing cages, and skips where guides are in use. Skips run without guides are very common in inclined shafts, and not one in a thousand has any sort of safety arrangement for stopping the skip in the eveut of a cable breaking, and this faet alone indicates that the application of a safety device to this condition is unusually difficult. The field for the iuventive faculty in this direetion is large, and a device which would aecomplish the desired object would be gladly welcomed by mine managers the world over.

The Need of Ventilation.

The explosiou of nitro powder in mines creates a qnantity of earbonic oxide, and nitrous gases, which mixed with the oxygen of the air, make a combination not only detrimental to health when breathed, but even deadly. There are numerous so-called remedies for "powder headache," but none of them aetually afford immediate or complete relief, and it is a question whether these compounds do not do more damage to the stomach and the digestive organs thau is compensated for by the partial relief of the head, by a process of deadening the nerves. Good ventilation is the best thing, as it will tend to prevent powder headache. It is also advisable to use nothing weaker than XXXX caps, aud "five X" or "six X" are even better, as these have a tendeney to ereate a more perfect explosion of the powder, with a consequent less amount of smoke and gas. Powder gas is not always visible. Carbonic and nitrous oxide may exist in considerable quantity in a perfectly clear atmosphere. This is often the case and shows the necessity of perfect ventilation. Often when a round of holes have been fired in a shaft or drift, and the smoke all driven ont by the ventilating pipes or allowed to drift away uaturally, the miners are made ill by shoveling up the rock into cars—the entire mass of broken rock being saturated with the gases of the explosion. This is particnlarly the case with rock that breaks up fine and is moist.

Rapid Shaft Sinking.

The record shaft sinking done ou some of the mines of the Rand in South Africa has a tendency to make the average mine snperintendent in Ameriea think he is not thoronghly acquainted with his business. The reeords made iu some of the shafts of the Rand, where considerable over 200 feet of shaft has been completed in a single month in a number of instances, is a matter for consideration and compels the admiration of those in the mining west of the United States, where 150 feet of shaft per month is far beyond the average, but it must be remembered that the conditions are different on the Rand from those obtaining in America generally. The shafts where these nnusual feats have been accomplished are mostly vertical. The rock is firm quartzite, not very hard, bnt good standing ground for most part. The drilling is generally done by Kaffir "boys," who strike, as a rule, single hauded, and are placed on the bottom as thickly as they can possibly be situated aud work. They are from 50 to 200 feet below the timbers while sinking, and there are no delays on aecount of broken timber; there is usually little water to handle, and it would appear that generally they have every natnral advantage, aud few of the disadvantages of mines elsewhere. Under so favorable a set of conditions it is possible to accomplish what appears to be far in excess of the ordinary accomplishment of able men in other regions. In the metal mines of the West the miner has, as a rule, hard rock, a greater or less abnndance of water, too often a shaft too small to admit of the best results in the effort expended iu the work; timbers must be earried close to the bottom of the shaft which necessitates delay in repairing damages, or in taking the necessary precautions to prevent it. Still under these adverse eonditions excelleut work is often done under competent direction, and the fact that fewer feet of shaft are completed here than in South Africa is not an index of relative incapacity on the part of either manager or workmen. Some of the most difficnlt mining engineering problems have been solved in the opening of Ameriean mines.

The Outlook for Copper.

The producers of copper are looking hopefully, if not anxiously, for an increase in the price of the metal, but with no immediate prospect of an advance, unless the war which is now actually on in the Orient results in increasing the demand for copper and for lead also. While the great industrial activity of America and Europe and the development of Africa is calliug for constautly increasing amounts of copper, the priee remains nearly stationary, for the reason, prineipally, that the prodnction is iucreased as fast as the demand is created for the metal. Not only are uew copper mining enterprises frequently entering the competitive market with their product, but the larger and long established eoncerns are in mauy iustances increasing their output. Old machinery and methods are giving plaee to the new, with a view to increasing produetion at decreased eost. The result is natural—there is no shortage in the market, and there is not immediate promise that there will be, unless it be created by an unusual demand, sueh as war, and there is no assurance that such a demand would not be promptly met by the forced output thns stimulated under the inereased price of the metal. The newly reported combination between the Amalgamated Copper Company and the Rothschilds interests, if correct, has not made its influeuce felt in the copper market as yet. It is not improbable, however, that when this influence is noticeable, if at all, it will be for lower rather than higher copper, for there are still many important mines not as yet within the control of the new combination.

THE necessity for careful examination of every elass of rock eoming from a mine is again emphasized in the occurrence reported from the Eagle mine, near Lawson, Clear Creek county, Colo., where a few days since the manager decided to ship to a smelter a qnantity of ore regarded as worthless by some of the men and which was being thrown over the dump. The result, as reported, was $35 net per ton. This is not the first instauce on reeord where rock regarded as worthless has proven eventually to be the best ore in the mine.

CONCENTRATES.

TELLURIUM in copper has the same effect as sulphur in iron, "short."

✻✻✻✻

CYANIDE has no action or reaction on metallic gold in the absence of oxygen.

✻✻✻✻

THE rock specimens from Bisbee, Ariz., are: No. 1, the variety of silica known as chert. No. 2 is probably felsite; the green color is due to iron.

✻✻✻✻

THE exact amount of zinc consumption in gold precipitation in the cyanide process is not procurable, but it is believed the aggregate so used is not above 1000 tons annually.

✻✻✻✻

THE district of Alaska has no legislative powers, therefore the manner of locating and recording mining claims is governed solely by Federal statutes and local regulations.

✻✻✻✻

ONE POUND of silica in the blast furnace combines with lime, iron, etc., to form three pounds of slag. It is figured, theoretically, that it requires 0.87 pound of coke to smelt one pound of silica in the charge.

✻✻✻✻

THE rock specimens from Indio, Cal., are black obsidian—volcanic glass—and not anthracite coal. This glass occurs in abundance near Volcano Springs, below Salton, from which vicinity those specimens probably came.

✻✻✻✻

WHERE a cage is used in a shaft a bucket may be suspended beneath the cage for the purpose of sinking, and by using long shoes on the cage, which extend upward 18 or 20 feet, the cage may be safely lowered so that the bucket rests on the bottom.

✻✻✻✻

IT is stated (Bloxam's Chemistry, page 25, edition 1903) that even among solids the phenomenon of diffusion is not unknown; thus a piece of gold laid upon a piece of lead will gradually diffuse through the lead, but it is a process requiring years.

✻✻✻✻

PITCHBLENDE is not a "flinty" mineral. It is massive, and the specific gravity is often lower than in the other uranate minerals. It is usually accompanied by base mineral sulphides, is dark in color, with gravity of 6 to 6.5. It occurs at Basin, in La Sal mountains, Grand county, Colo.

✻✻✻✻

THE suction hose of a sinking pump should be secured with ropes in such a way that the vibration caused by the operation of the pump will not cut a hole through the hose by contact with the rocks. Neglect to take this precaution often results in cutting a hole through the hose in a few hours.

✻✻✻✻

THE phenomenal richness of the chloride ores of Fryer Hill, Leadville, Colo., found there in the early days of that camp, can only be explained on the theory of secondary enrichment, for throughout the Leadville district the oxidized surface ores were uniformly richer than the ores of the sulphide zone.

✻✻✻✻

SHAFT GUIDES should extend upward from the collar of the shaft at least as high as the shaft of the sheave wheel, so that in case of overwinding the safety clutches with which cages and skips are, or should be equipped, shall not spring outward in the event of the cable breaking, and fail to clutch the guides at all.

✻✻✻✻

AT Virginia City, Nevada, an attempt to work slimes from mill tailings proved so difficult that it was determined to work the croppings of a mine in a mill and mix the relatively coarse sands with the fine slimes. The result is said to have been satisfactory. The mine croppings in this case contained gold in excess of that in the slimes.

✻✻✻✻

A BODY of ore in a vein is called an "ore shoot," and a device for passing rock from an ore bin or pocket to a car or other receptacle is known as an "ore chute." The necessity for avoiding misunderstanding and for having means of distinguishing between the two words has made this acceptance and use of the two different terms.

✻✻✻✻

IT is always economy to cover a steam boiler no matter how cheap the fuel. A cover should be employed which is readily removable for the purpose of inspection of the boiler. There are many materials used for covering steam boilers and pipes, among them wood strips, hair felt, magnesia boiler covering, sawdust, plastor of paris, paper pulp, etc.

✻✻✻✻

THE quantity of iron required to precipitate a pound of copper from solutions containing the same in the form of sulphate is variable, depending upon the character of the iron and percentage of copper in the solution; but it may be safely said to always exceed the theoretical requirement. A greater or less amount of iron oxide is always present in the precipitate.

✻✻✻✻

ARSENIC OR ANTIMONY in the zinc used for precipitating gold from the cyanide solutions is detrimental, but the presence of a small amount of lead in the metal is said to act to an advantage as there is a certain electrolytic action induced. The amount of gold a given weight of zinc thread will precipitate in a given time depends upon the strength of the solution and its value in gold.

✻✻✻✻

AN unusual variety of minerals has been found in the granite dikes near Pala, San Diego county, Cal. Prominent among them are rubellite (pink tourmaline), lepidolite (lithia mica), various other varieties of tourmaline, mica, quartz, feldspars of several varieties, and the new mineral kunzite, a variety of spodumene which occurs in transparent crystals of hyacinth color.

✻✻✻✻

PYRRHOTITE is rarely employed in the manufacture of sulphuric acid, for the reason that pyrrhotite contains too low a percentage of sulphur—about 39.6. Pyrite or pyrite and chalcopyrite are generally used for this purpose. Pyrite contains 53.4% sulphur and chalcopyrite alone but 35%. Chalcopyrite is only used incidentally, when it chances to accompany pyrite.

✻✻✻✻

THE expedient of sinking through quicksands or soft, running, wet ground by means of freezing the ground is resorted to in extreme cases, where all other methods of making progress fail. A shaft may be sunk by means of a caisson-like structure, the sections being added at the top and forced downward, as the work of excavation proceeds below, by means of heavy weights or jack screws.

✻✻✻✻

THE only minerals thus far known which produce uranium in commercial quantities are pitchblende and carnotite. Most uranium minerals are of high specific gravity, and concentrate without great difficulty by the usual process of concentration. The disposition to overload concentrating machines with the use of too much water is often responsible for poor work in this direction.

✻✻✻✻

WHEN a current wheel is raising water to its full capacity it is being employed to the best advantage. The connection of the shaft of the wheel to a pump of any description would not give as satisfactory results, owing chiefly to friction. Such a wheel would not raise a larger volume of water to the same height as before, nor as much as before—though it might raise a smaller quantity to greater height.

✻✻✻✻

THE average prospector generally profits to a greater extent by the search for gold than in hunting for rare minerals like pitchblende or some of the other rare minerals. In the quest for these he is apt to overlook something of greater value, and that which is more readily converted into money. Oftentimes he is not well informed as to the physical appearance of rare minerals and generally knows little of their chemical reactions, and is unprepared to make tests.

✻✻✻✻

THE first tunnel to be driven under the Hudson river between New Jersey and New York City is nearly finished, there still remaining about 200 feet to be accomplished. The excavation is driven through solid, hard rock, soft rock, sand and silt. A second tunnel parallel with the first is well under way, having been begun in November, 1903. It is estimated that progress will be at the average rate of 30 feet per day. This tunnel has been advanced over 1300 feet within four months.

✻✻✻✻

ONLY the best quality of fibrous ashestos is suitable for weaving fabrics of this class of material, but ashestos of inferior quality may be used in making a felt-like cloth by admixture with other substances, which is also fireproof. Fine ashestos fibers become brittle after heating to a high temperature, and for this reason it is inexpedient to cleanse asbestos cloth by placing in a fire. The variety known as crysotile is the finest in fibre and flexibility. It is found in small veins traversing serpentine.

✻✻✻✻

THE rock specimens from Volcano, Cal., are, 1, granodiorite; 2, diorite; 3, amphiholite schist, probably the result of the alteration of the diorite. It may be from the vicinity of a fissure or a vein. There is no probability that in sinking in the granite the shaft will come into serpentine, or into black clay slate, unless either of these rocks are known to exist in the near vicinity, and to be dipping in the direction of the shaft. A gold-bearing vein can exist in either the grano-diorite, the diorite or between the two.

✻✻✻✻

IN the case of trespass and the removal of ore by another person than the owner, the United States Supreme Court said, in case of Woodenware Co. vs. the United States, "that in innocent or unintentional trespass the trespasser may deduct the cost of mining and raising to the surface; but if the invasion is willful, no such deduction can be made. Where ore has been mined and raised to the surface, and a demand is made for it and refused, the owner may recover the value in the condition it was at the time the demand was made."

✻✻✻✻

IT is claimed by J. Park, an English authority on cyaniding ores, that in the treatment of concentrates the best results are obtained when the pyrites and sand exist in the proportion of five to one. He further says that "pyritic concentrates may be leached by agitation with cyanide or by percolation, as with ordinary tailings. Both methods give satisfactory results." Experiments made in treating raw auriferous sulphides have demonstrated that fine grinding is indispensable to the successful treatment of raw sulphides. It has also been shown that some sulphides are much more amenable to the process than others.

✻✻✻✻

THE mineral specimens from Chaffee county, Colo., are: The rock, impure graphite; the fine material, impure graphite, probably same as the solid rock, but crushed by earth movements. Samples might be submitted to the Jos. Dixon Crucible Co. of Jersey City, N. J., for an opinion as to its commercial value. Under the pressure of moving rock masses coal is sometimes ground to powder and altered to graphite, but it is improbable that this occurrence is due to this cause, though the presence of so large an amount of carbon indicates the probable prior existence of abundant carbon in some form in the rocks.

✻✻✻✻

IN the electrolytic assay for copper, the presence of other metals interferes to a greater or less extent with the accuracy of results. If silver be present, it should be first removed by precipitating with hydrochloric acid. Bismuth, if present, is precipitated with the copper, and it must be determined analytically in the deposit. Lead, if present in the form of sulphate, is partly precipitated with the copper, but this mineral does not interfere with the process unless it be present in large amount. Zinc and nickel do not cause any trouble and may be disregarded. Arsenic precipitates partly with the copper and not after it. After complete deposition, the deposit should be titrated with cyanide of potassium.

✻✻✻✻

THE rock specimens from Encinitas, Cal., are essentially quartz, though altered from either granite or diorite. The quartz contains a large percentage—8% to 10%—of iron sulphide, with a small amount of copper sulphide. It may contain gold and silver. The ore should concentrate readily, and, if the values are in the sulphides, these should contain enough to pay to work. The first consideration is whether or not the ore as a whole contains sufficient value to pay for mining, crushing and concentration of the sulphides and the treatment of the latter. This can be determined by samples carefully taken and assayed by a competent person. A comprehensive knowledge of the cost of mining and treatment of ores is also essential in considering the question. As the iron is sulphide, it is not likely that any material change will take place in the manner of its occurrence, other than that of its appearance in the quartz in greater or less quantity than that found at the present depth.

✻✻✻✻

IT is known from experience that blasting the full round of holes simultaneously by electricity in shaft sinking does not produce as satisfactory results as when the "cut" is fired first, followed by the intermediate holes, the end holes being fired last. When the full round is fired by the electric spark the action is instantaneous. The usual result is, in hard ground, that the cut breaks well, the next line of holes fairly well, and often the end and corner holes do not break at all. Nitro powder is very powerful, but it must be given a chance, and situated as is the end line of holes and those adjoining them in a large shaft, it may be truly said the powder has no chance under such conditions. With the cut broken out and the intermediate line of holes following, the end holes should also break as the holes previously fired have created a "stope" for the end holes. There are cases where the entire round may be fired at once and the holes all break, but where this can be done the damage to timbers is usually severe if they be required close to the bottom.

✻✻✻✻

THE rock specimens and drillings from Virginia City, Mont., are: The rocks, basalt; the coarse material wrapped in separate paper is also basalt. Bottle No. 1 contains abundant quartz grains, and some feldspar; No. 2, a large amount of iron ore (limonite), colored quartz grains, transparent zonal feldspars, fragments of obsidian, opaque feldspars. Fragments of the several minerals are sub-angular. Contains less quartz than No. 1. This material evidently came from a layer of sand underneath the basalt, and is derived from an older rock. The fragments of obsidian may be accidental—coming from the upper portion of the bore hole. No. 3 consists of white, colorless and colored transparent quartz grains, and feldspar. Grains are mostly sub-angular. No. 4 contains quartz grains, feldspar and small amount of limonite. All of the sands from the four bottles are from rocks or beds of fragmental material older than the basalt flow. The fact that no gravel was encountered between the basalt and bedrock is not proof that there is no older gravel channel beneath the basalt. It may lie at one side or the other. The samples contain no mica or hornblende, which may indicate that the drill is in compact sand, and that bedrock has not yet been reached by the bore holes. Would suggest the advisability of sinking a little deeper to determine whether bedrock has been reached or not. If the limits of the basalt are defined by older rocks on either side of the gulch, then it would be advisable to bore additional holes at stated distances entirely across the lava flow in search of a possible older channel, as it is not necessary that the older channel be directly under the more recent one. If the lava flow is later than Tertiary there is a reasonable probability of the existence of an older channel beneath the lava. The ancient channels of California were formed in late Tertiary.

Some Features of Mining Operations in the Homestake Mine, Lead, South Dakota.

Written for the MINING AND SCIENTIFIC PRESS by
BRUCE C. YATES, E. M.*

The Homestake Mining Co., as it exists to-day, is a consolidation of the Father De Smet, the Deadwood-Terra, the Caledonia, the Highland and the Homestake gold mining companies. The property comprises some 350 locations with a total area of 2624 acres.

The ground upon which mining operations are being carried on at present lies between Deadwood gulch on the north and Whitewood gulch on the south, covering about 10,000 feet along the strike of the ledge. The principal works and the offices of the company are located almost in the heart of the town of Lead, which has a popoulatiou of about 8000. The town is built on either side of Gold Run gulch, which is a tributary of Whitewood gulch and which passes through the company's property from west to east a little south of the center. The strike of the Homestake ledge is approximately N. 35° W. and S. 35° E. The dip is very irregular.

The compauy is now operating 900 stamps and an additioual 100 stamps will be installed during the present year. The 900 stamps are grouped in six mills. The Homestake aud Golden Star with 200 stamps eaeh and the Amicus with 140 stamps are located on Gold Run gulch, the Pocahontas with 160 stamps and the Monroe with 100 stamps are located on Bobtail gulch, which is a tributary of Deadwood gulch. The Mineral Poiut mill with 100 stamps is located ou the south side of Deadwood gulch and near the uortherly end of the property. The tailings are treated at two cyanide plants. One with a capacity of 1450 tons per day is located on Gold Run below the Homestake, Golden Star and Amicus mills and treats the tailings from these mills. The other, with a daily capacity of 800 tons, is located on Deadwood gulch at the mouth of Bobtail and receives the tailings from the Pocahontas, Monroe and Mineral Point mills.

The ore is principally free milling, 72% being caught on the plates. The total recovery is approximately 88% of the assay value. (See paper on "Metallurgy of the Homestake Ore," by C. W. Merrill, Met. Eng., read before the American Mining Congress at its 1903 meeting iu Lead, S. D.*)

The main source of the water supply is the headwaters of Spearfish creek. A pumping plant consisting of two Fraser & Chalmers compound Corliss pumps, with a third now being installed, is located near the head of the East Fork. The water is pumped 400 feet to the top of the divide between Spearfish and Whitewood creeks, from which point it is carried by gravity to the main reservoir at Lead, some 10 miles in all.

A very small volume of water is pumped from the mine eonsidering that there are about 41 miles of track now open. The water was formerly taken care of by a Cornish pump, which lifted the water in three stages from the 800-foot level to the surface until about two years ago, when a Fraser & Chalmers compound Corliss pump with a capacity of 550 gallons per minute under a head of 1200 feet was installed on the 1100-foot level.

The underground haulage is done by horses and mules. The horses seem to be better adapted to the work than mules and in consequence there are very few mules left in the mine. The cost for horse haulage is $0.03 per ton per 1000 feet.

A five-ton air motor has been ordered and will be tried on one of the lower levels. If successful, these motors will, no doubt, take the place of horses on all main haulage ways. A fifteen-ton motor is now being used on the tramway level to haul ore from the crusher bins to the mills. The air is supplied at a pressure of 950 pounds by a 100 H. P. three-stage straight-line compressor which will serve both motors temporarily.

Following is a tabulated statement of the power required to carry on the different operations:

MACHINE DRILLS.

Manufacturer's Name.	Size.	No. in Use.	Purpose Used For.	Remarks.
Ingersoll	A-32-2¼-inch	48	Block holing	Six of the Ingersoll are used for Ajax drill sharpening machines and two are used for shop welding in car repair shops.
Ingersoll	B-32-2½-inch	12	Upper levels and surface	
Ingersoll	D-32-3½-inch	30	General mining	
Ingersoll	D-24-3-inch	148	General mining	
Rand	3½-inch	2	Shaft sinking	
Leyner	3-inch	3	Surface drifting	
McKiernan	3-inch	1	Shop hammer	

ELECTRIC MACHINERY.

Manufacturer's Name.	K. W. or H. P.	How Driven.	Where Used.
Edison	8½ K. W. generator	Connected to line shaft	Cyanide No. 2.
Westinghouse	22 K. W. generator	Conneeted to line shaft	Cyanide No. 1.
Edison	6 K. W. generator	Driven by 10 H. P. Ideal engine	Munroe mill.
Edison	2 (60) K. W. generator	175 H. P. upright engine	B. & M. shaft.
Gen. Elec. & C. & C.	2 (5) H. P. motors	Connected to mill shaft	Amicus mill.
Roth	2 H. P. motors		Homestake office.
Edison	2 (20) K. W. generators	Line shaft from engine	Golden Prospect shaft.
Edison	17½ K. W. generators	25 H. P. Ideal engine	Mineral Point mill.
Brush	4½ K. W. generators	Connected to mill engine	Pocahontas mill.
Gen. Elec.	4½ K. W. generators	10 H. P. Ideal engine	Pump station.

HOISTING ENGINES.

Manufacturer's Name.	Kind of Engine.	H. P.	Where Used.	Remarks.
Union Iron Works	Simple duplex	1,200	Ellison hoist	
Fraser & Chalmers	Simple geared duplex	150	Golden Star hoist	
Fraser & Chalmers	Simple duplex	400	B. & M. hoist	
Fraser & Chalmers	Simple duplex	500	Golden Prospect hoist	
Fraser & Chalmers	Simple geared duplex	150	Old Brig	
Fraser & Chalmers	Simple geared duplex	150	Golden Gate	

CRUSHER ENGINES.

Fraser & Chalmers	Compound Corliss	250	Ellison hoist	
Fraser & Chalmers	Simple Corliss	250	B. & M. hoist	
Fraser & Chalmers	Simple engine	200	Golden Prospect	
	Simple engine	100	Old Brig	
Fraser & Chalmers	Simple engine	200	Golden Gate	

MILL ENGINES.

Geo. H. Corliss	Cross compound	500	Homestake mill	
Geo. H. Corliss	Tandem compound	500	Golden Star mill	
H. Corliss	Simple Corliss	350	Amicus mill	
Fraser & Chalmers	Simple Corliss	350	Pocahontas mill	
Union Iron Works	Two simple engines	125	Monroe mill	Each 125 H. P.
Union Iron Works	Simple engine	250	Mineral Point	

AIR COMPRESSORS.

Ingersoll-Sergeant	2-stage compound Corliss	1,000	Ellison hoist	Low pressure.
Ingersoll-Sergeant	3-stage straight line	100	Ellison hoist	High pressure.
Ingersoll-Sergeant	Duplex	500	B. & M. hoist	Low pressure.
Ingersoll-Sergeant	Duplex	300	Golden Prospect hoist	Low pressure.
Ingersoll-Sergeant	Single engine	100	Cyanide No. 1	Low pressure.
Ingersoll-Sergeant	Single engine	100	Cyanide No. 2	Low pressure.

PUMPS.

Fraser & Chalmers	Compound Corliss	250	Mine—1100 feet	
Fraser & Chalmers	Two compound Corliss	325	Spearfish creek	Each 325 H. P.
One Holly, two Dean	Compound Corliss	50	Settling dam	Each 50 H. P.
Fraser & Chalmers	Simple Corliss	250	B. & M. shaft	Cornish.
Three Prescotts	Compound	40	Cyanide No. 1	Each 40 H. P.
Two Heisler	Triple expansion	40	Cyanide No. 2	Each 40 H. P.

MISCELLANEOUS.

Kind of Engine.	H. P.	Where Used.	Remarks.
Simple engine	25	Ellison shaft	Sinking engine.
Simple engine	30	Amicus mill	Derrick.
Simple engine	100	Machine shop	
Simple engine	25	Pump station	Rock crusher.

In this paper no attempt will be made to give more than a few facts in regard to the mining operations of the Homestake miue, and much of the matter contained herein may sound commonplace to many experienced mining men. If any of the methods described are original, it should be borne in mind that they have stood the test of actual miuing operations in a mine where a large daily tonnage at a minimum cost is the object aimed at.

The illustration on the front page is that of some of the company's buildings and part of the open cut at Lead. The aecompanying engravings are views of the Ellison hoisting engine and the sand vats of cyanide plant No. 1.

SHAFTS.—The Homestake Mining Co. is now operating six shafts, the Ellison, B. & M., Golden Star, Golden Prospect, Old Brig and Golden Gate. Three of these, the Goldeu Gate, Old Brig and Golden Prospect, have reached the 800-foot level, while the Ellison, B. & M. and Golden Star have reached the 1100-foot level.

Four of these shafts are located on the hanging wall side of the ledge, one on the foot wall side and one is sunk in the ledge. All are conneeted by permanent drifts driven in the "country" rock.

The Ellison is a large, three-compartment shaft; two compartments beiug used for hoisting and one for ladders and pipes. The two hoisting compartments are 10 feet by 5 feet in the clear. The third or ladder compartmeut is 10 feet by 6 feet in the clear. The Golden Star and Old Brig each have three equal compartments 4 feet 6 inches by 5 feet in the clear. The B. & M. is similar, with the exception that there is a fourth compartment reaching the 300-foot level, in which is operated a third cage. The Golden Prospect originally had only two compartmeuts, one being 9 feet 6 inches by 5 feet in the clear and the other being 4 iuches wider to provide for pipes. Later a third small compartment was added from the 500-foot to the 800-foot levels, in which are plaeed the ladders and pipes. The timbering in the Golden Gate shaft is slightly different from the other standard three-compartment shafts, but the dimensions are the same.

After the first 200 feet from the surface, the shafts, with the exception of the Golden Star, are sunk in a hard carbonaceous wall slate. The dip of the slate intersects the axis of the shafts at angles varying from 60° to 90° from the horizontal, which makes blasting the cut quite difficult.

During the early history of the Homestake and associated mining companies these shafts were not connected by underground workings. Each is now a factor in the mining operations of the compauy and through each is carried on some part of the work incident to the mining of about 4000 tons of ore each twenty-four hours.

When sinking is resumed in auy of these shafts, it is necessary to provide hoisting facilities to carry on this part of the work independeut of the regular cages. This is accomplished by using a small 25 H. P. hoisting engine, driven by compressed air, which is placed on the lowest working level of the shaft. In the operation of this engine it has been found necessary to reheat the air before it is used in the cylinder, and this is done by passing the air through several coils of pipe surrounding a small sheet iron stove, heated by coke. A bucket with a capacity of one-half ton is used instead of a cage to hoist the rock and men. No guide head is used, plank being nailed on the inside of the timbers to prevent the bucket striking on the timbers. A small sheave wheel is placed just above the station set.

The men are well protected by bulkheads thrown across the shaft just above the sheave wheel or below the station on which the engine is located. The shaft is sunk 200 or 300 feet in this manner. Stations are opened on the new levels and crosscutting is commenced. Drifts are run to other shafts of the belt, which are tapped by small raises. These raises serve the double purpose of providing ventilation and acting as a chute through which the rock is dumped as the sides are stripped down to make room for the regular shaft timbers.

Miners working in the shaft are usually under contract. The engineers, landers to dump the rock from the bucket into the cars and timbermen are paid by the day. The company furnishes tools and sharpens drills, the coutractors furnish candles, powder and pay for repairs on machines and assist in placing timbers.

The following statement shows the number of men employed in sinking at the Ellison shaft: The number of men employed on each shift is four miners (contractors), one engineer, one lander, one timberman, one carpenter two and one-half shifts, framing one set of timbers, which provides for 6 feet of the shaft.

The actual time consumed in placing one set of timbers is eight hours, but the timbermen are kept busy one shift in each twenty-four hours, running timber from the sawmill and putting in extra bracing.

(TO BE CONTINUED.)

A Correction.

TO THE EDITOR:—I find in the article on "Automatic Ore Sampling," in your issue of January 30th, page 79, five lines from bottom of first column, I have used the words "cut down to the desired size by the riffles before going to the riffles," it was iutended to be—"cut down to the desired size by the riffles before going to the sample grinders."

Denver, Colo., Feb. 6. ALFRED HARVEY.

THE fact that a series of metamorphic rocks—schists or slates—are cut by intrusive dikes does not signify that the metamorphosed rocks were of igneous origin, for dikes cut metamorphic rocks which have had fragmental origin.

Tenth Annual Report of the Portland Gold Mining Co., Cripple Creek, Colo.

In the tenth annual report of The Portland G. M. Co. of Cripple Creek, Colo., for the year 1903, President J. F. Burns states that they have opened up twenty-three new ore bodies during the three months prior to Jannary 1, 1904, and have placed more ore in sight dnring that period than was taken out in six times that length of time.

Dnriug the year 1903 the company pnmped no water and the lower level of the mine is practically dry. It has been demonstrated that the Portland is not within the zone drained by the El Paso tunnel, as the drainage through the tunnel has not affected the property.

During the past year the development has kept ahead of the production, and a littlc more than 4 miles of crosscuts, drifts, etc., were made during the year, making a total in all, up to January 1, 1904, of close to 27 miles of underground workings.

For the month of November, 1903, 2717 feet of development work were done, which was the highest in the history of the company, aud other records have been broken, both as regards production and cost.

During a shnt-down of abont ten days during the strike a general clean-up at the mill took place.

It was stated in the eighth annnal report that "there was an intricate network of veins within the company's territory that are yet unexplored, but which will be intersected in exteuding onr present workings on the various levels." The recent development work in exploiting these veins has more than fulfilled the predictions.

A large number of the new strikes referred to have been made iu these veins and in nnexplored territory, resulting in increased ore reserves.

The treasurer's balance sheet shows the following:

MILL DEPARTMENT—CLOSE OF BUSINESS FOR THE YEAR 1903.

Portland G. M. Co.		$ 223,056.62
Ore account	$2,756,845.42	
Treatment charges		770,293.37

From April 1, 1894, to Dec. 31, 1903, the Portland mine produced 465,741.134 tons of ore, worth $18,081,542.72.

The report of F. M. Kurie, assistant general manager, gives the following tables of costs for development work and stoping for the year 1903, which is the lowest in the history of the company:

	19,808 Feet. Cost per Foot Drifts and Crosscuts.	1451 Feet. Cost per Foot Raises and Winzes.	Cost per Ton Stoping.
Breaking—			
Machinemen & miners	$1.969	$3.458	$0.369
Shovelers	.038	.193	.218
Air and air drills	1.049	2.02	.179
Explosives	1.444—$4.50	1.617—$ 7.288	.139—$0.905
Tramming—			
Trammers	.966	.883	.175
Pipe and trackmen	.124	.009	.008
Gen. tramming expense	.098— 1.188	.103— 1.055	.034— .217
Timbering—			
Timbermen	.029	1.503	.215
Lumber and timbers	.017— .046	.947— 2.45	.310— .525
Hoisting	.583	.604	.254
General expense	.70	.735	.291
Total average cost	$7.017	$12.132	$2.192

DECEMBER COSTS—THE LOWEST FOR THE YEAR 1903.

	Cost per Foot Drifts and Crosscuts.	Cost per Foot Raises and Winzes.	Cost per Ton Stoping.
Breaking—			
Machinemen & miners	$1.841	$3.958	$0.341
Shovelers	.....	.....	.202
Air and drills	.866	1.326	.159
Explosives	1.307—$4.014	1.201—$ 6.485	.125—$0.827
Tramming—			
Trammers	.884	1.077	.152
Track and pipemen	.105	.029	.008
Gen. tramming expense	.038— 1.027	.129— 1.235	.014— .174
Timbering—			
Timbermen	.....	1.363	.15
Lumber and timber	.008	.679— 2.042	.225— .375
Hoisting	.473	.828	.208
General expense	.578	.906	.246
Average cost	$6.10	$11.496	$1.83

The pumps were not run during the year. No trouble of any kind was experienced with water.

Metallurgical Practice on the Witwatersrand, S. A.*

Discussing a paper ou metallurgical practice on the Rand, South Africa, by H. S. Denny, J. R. Williams says:

SORTING.—As I am certain that others who have gone carefully into this question, which is of the greatest importance, will deal fully with it, I will content myself with the remark that I take exception to an extraction of only "80% from all sonrces." Thus, if, for instance, you take the case of a mine where an extraction of 60% is obtaiued in the mill (of which we have several examples), to obtain 80% the secondary treatment plant only calls for an extraction of 50%. Surely, Mr. Denny will admit that he is not satisfied with 50% extraction from his cyanide plants. If 90% extraction from all sonrces is taken (this was about the average of the Rand mines subsidiary companies when in full swing before the war), Mr. Denny will find it necessary to considerably modify his figures.

MILLING.—The anthor questions the jndgment of the various managements in the nse of screens, and wonld make us believe that from the Robinson to the Heriot the same screen should be used. Mr. Denny states "there is no special differentiation, so far as the writer is aware, which, from a metallurgical standpoint, can be claimed as determining a necessity for a variation in mesh from 400 to 600." As I have the honor to be consulting metallurgist to ten compauies in this area, for Mr. Denny's information I will state that actual practice has shown us that there is every difference. As a case in point, when the Nourse Deep commenced crushing, because a 700 screen was found advantageous to the other deeps, the same screen was tried, with the result that very high residnes were obtained. Examinatiou of these residues showed that the gold was encased, but the nse of au 800 screen at once gave an increased percentage by amalgamation, and the cyanide works residues were reduced by more than a pennyweight in value. At the Ferreira Deep exhanstive experiments proved that it was absolntely necessary to use a 1000 screen. A 1200 screen was also tried, but it was fonnd that the nse of the 1000 screen was the most profitable.

Mr. Denny contradicts his own statemeuts. He says: "Although the banket ores of the Witwatersrand main reef series may be jnstly described as being remarkably uniform in mineralogical character, there are physical variations in their coustitntion that are of considerable metallurgical interest, these having a marked influence on their amenability to different methods of treatment," and fnrther says, "it is clear that in consequencc of these differences the treatment at one mine may vary considerably from that at another." May not finer crushing be one of the necessary variations? I think so and am pleased to find that Mr. Denny and myself agree. He states: "We have the cyanide process, which, in some cases, on a charge containing about 20% of concentrates, will, given a long treatment, show an extraction of 90%, bnt in others the latter figure does not reach 50%. Even in those cases where it is claimed that the process is doing satisfactory work the expeuditnre, when taken with the valne of the residnes calculated npon a comparatively clean concentrate, represents an amount in the matter of costs which certainly admits of considerable improvement," and he also forcibly shows that with finer grinding a high extraction can be obtained even in those ores of apparently a refractory natnre. I am certain that, from an extraction point, Mr. Denny will attain every snccess by his proposed system of regriuding.

AMALGAMATION.—Mr. Denny gives us what he calls a curions fact, that the extraction by amalgamation decreases from west to east. I should like some figures to substantiate this statement, and would bring to his notice that for the twenty odd companies with which I am connected the highest extraction by amalgamation is obtained on the Ferreira Deep, about the center of the Rand; that for a year before the war, the New Modderfontein, our most eastern company, gave 60.5%, while the French Rand G. M. Co., the most western of our group, gave 53.67%.

I do not nnderstand the paragraph referring to the use of lime. Does Mr. Denny want to take credit for the use of lime in the mill? I may say that as far back as 1871 R. W. Raymond in his work, "Mining Statistics West of the Rocky Mountains," makes the following remarks: "The worst form of discoloration of plates proceeds from the action of sulphates of iron or copper present in many ores, from the natural decomposition of the pyrites. The addition of lime to the water introduced to the battery, as much as will dissolve therein, will nentralize the carbonic acid and decompose the sulphates. It may be found necessary to add lime to the ore to furnish enough to react on all the sulphates," and, further on, in the stock of individnal chemicals which should be kept iu the mill, "caustic or nnslaked lime" is mentioned among others; and in a paper read by myself before this Society in April, 1899, on "The Indirect Advantages of a Slimes Plant," I gave figures showing the increase in amalgamation, as well as the saving in water.

The writer pnts down the amount of mercnry lost per ton milled at 1.3 ounce. If this is really so, and it is not an error in the decimal place, all I can say is that it denotes bad work. Ou 6000 stamps this will work ont at 2430 ponnds per day, or over 400 tons per annum. The average for the snbsidiary companies of the Rand Miues, Ltd., from January to August this year was 0.129 ounce per ton, and to show what can be done with careful outside amalgamation, I would like to place on record that Mr. Bevington, at the Village Main Reef G. M. Co., does not exceed 0.07 ounce per ton.

Mr. Denny again contradicts himself in saying: "It is obviously to the great advantage of the mines to secure from their mills a maximum crnshing efficiency—since it is only as a crnshing medium that stamps are regarded—in order to economize on capital expenditnre for plant, for bin provision, buildings, etc." Elsewhere he says: "Our most simple process is, therefore, responsible for two-thirds of our gross revenue, and as all our snbsequent operations are expensive, and are only moderately efficient, it is of the utmost importance to do everything possible to keep our amalgamation practice at its greatest efficiency. Every pennyweight of gold that passes over the plates only yields, on an average, 80% to 85% in our subsequent operations, and carelessness in amalgamation thus results in heavy loss." Which are we to accept? I should undoubtedly say the latter.

CONCENTRATION.—I fail to find anything new on concentration not covered by the concentrates committee and reported by the Chamber of Mines in their "Aunual Report for 1894," but I take exception to his taking one company as showiug what extractions can be obtained from spitzlntte prodnct. If Mr. Denny will take the case of the adjoining company he will find that the extraction ou this product amounts to 89.61% for the year ended August 31, 1903, and that the average of the Rand mines subsidiary companies is not less than 85%; thus it will be necessary for him to modify his figures. Residnes of 3.160 pennyweights do not in any way represent the average work of the Rand.

Mr. Denny gives the constituents and values of ore after passing amalgam tables, and shows ns that: 35.6% of sulphurets extracted by vanners contain 82.9% of the gold; 51.4% of sulphurets in sands contain 15.3% of the gold; 13.0% of sulphurets in slimes contain 1.8% of the gold; which is, without question, a remarkable analysis, and different to anythiug in my own experience. I wrote to Mr. Denny asking him to let me have a sample of the tailings after passing the New Goch frne vanners, with which he furnished me. On this sample I carefully experimeuted, with the result that on grinding to pass a No. 30 mesh (900 screen), the sulphurets caught by ordinary panning assayed over twelve ounces to the ton, and not 21.9 pennyweights as shown by Mr. Denny, that using the well-known method of separation by specific gravity with a solntion of iodide of mercnry, the sulphurets obtained assayed over twenty ounces to the ton, and that the sands now freed from their free gold and sulphurets had a valne of under 1 pennyweight to the ton, and not 3.35 pennyweights as stated by the author, so I fear that his figures may not be taken as reliable.

*Abstract Jour. Chem., Met. and Min. Soc.

Electrical Smelting of Iron Ore.

Smelting iron ore by means of electricity has been successfully accomplished in several countries in Europe, namely, in France, Italy and Sweden, and also to a limited extent in the United States, says Electricity.

The Ottawa Government is now looking into the feasibility of this process of redncing ore with a view to its introduction in Ontario and Quebec.

In his recent presidential address before the Canadian Institute of Electrical Engineering, R. R. Gray, the president of that body, made the following reference to the electrical reduction of iron ores: "Another valnable process, which has made considerable progress during the past year, is the reduction of iron ores by means of the electric furnace. At Livet, in France, the process is in practical operation, generators of 1200 H. P., each giving single-phase currents at 30,000 amperes being employed. The ontput is twelve tons of steel per day. At these works ferro-silicon is also made from quartz, scrap iron and coke, at less cost than that of

smelting, and copper pyrites is reduced to copper and iron sulphides rich in copper and ready for the smelting process. Steel of high quality is similarly produced in Sweden at the rate of 1500 tons per annum. With the Stassue process, the expenditure of energy is said to be 3000 H. P. per ton of iron."

The Ottawa Government is now examining into the electrical process of smelting iron because in certain localities of Ontario and Quebec there exist extensive iron ore deposits which cannot be successfully worked owing to a lack of adjacent or available coal supplies. It is thought that if the energy now wasted in many waterfalls throughout the interior of the country can be used economically in smelting the ore it will open up a splendid field for profitable enterprise. Such should be the case providing the water power it is proposed to utilize is not too far distant from the ore deposits. At the present time, however, the test of profitable operation will be severe, owing to the low price of iron and steel.

Volcanic Ash in South Dakota.

To the Editor:—The occurrence of a material, usually called white sand, but really a volcanic ash, was located some years ago in the southwestern part of Custer county, S. D., and its value in the arts and manufactures has only recently been discovered. The property consists of 640 acres and is situated near the station of Argyle, on the B. & M. R. R., and 20 miles south from Custer. The material is siliceous and its color almost pure white. The deposit is located in what appears to have been a basin or lake. It is 4 miles distant from the limestone range in a southerly direction and is in the Tertiary formation.

This ash is said to have qualities similar to pumice stone, but does not possess the cellular structure, owing to the manner of its formation and deposition. It is supposed that the material, when molten, was accompanied by steam or other gases at the time of its ejection and that the bubbles formed in it burst, pulverizing the walls of the cells into very small particles, and these were deposited in the basin or lake. This layer of ash is overlaid by a deposit of fuller's earth and rests on a bed of hard, yellow, siliceous clay. This ashy material is used, like pulverized pumice, for a polishing powder and in the manufacture of scouring soap, and it is utilized in a compound for brightening brass, nickel and other metallic surfaces. It is in good demand and a ready market is found in the Eastern States. It is being shipped at the rate of fifty tons a month, with promise of an increase.

The development work applied upon the ground thus far shows the deposit to have reached a thickness of 6 feet, and is still increasing in thickness as work advances toward the basin of the dry lake.

W. H. Darton of the U. S Geological Survey says regarding the origin of this material:

"During the White River time (Tertiary) in the Black Hills and adjoining regions there was deposition of a considerable volume of volcanic ash. It appears to have been a period of volcanic activity in the region to the west, and the ashes were borne on the winds and dropped into the waters, so as to be deposited over a wide area of country adjoining the Black Hills. There is more or less volcanic ash throughout the White river deposits as an admixture with the clay and sand; accumulations of the pure material are often found at various horizons from the lower Chadron beds to the highest formation in Pine Ridge. In the Chadron formation the ash occurs in local lenses and is a general admixture. The most notable occurrence is in the fuller's earth deposit southwest of Argyle, where there is a bed of relatively pure ash having a thickness of 3 feet. Its composition is given in the following analysis made by George Steiger in the laboratory of the U. S. Geological Survey: Silica, 64.47; alumina, 14.74; iron (FeO_3), 2.73; iron protoxide, 0.78; magnesia, 0.29; lime, 4; soda, 2.55; potash, 3.31; BaO, 0.13; TiO_2, 0.76; P_2O_5, 0.29; H_2O, 5.71; total, 99.76. Its local extent could not be determined, owing to lack of exposure. The material consists of fine shreds of volcanic glass or pumice, mainly of pure white color and translucent, mixed with occasional flakes of dark-colored glassy material. It represents a rock of rhyolitic character."

This property is in charge of the writer.

Custer, S. D., Jan. 28. Denis Henault.

Phosphorescent Sphalerite.

To the Editor:—Referring to the interesting article by Mr. Eakle on the subject of "Phosphorescent Sphalerite" in your issue of January 23, I would like to note the occurrence of phosphorescent sphalerite in botryoidal masses, sometimes 1 foot in diameter, in the caves of the surface of the National Belle mine at Red Mountain, Ouray county, Colorado. The structure was radiated, and these "nodules" had been originally attached at some one point to the side of the cave. Often nearly concentric layers were visible. In opening the mine in 1885 I often encountered them. United States Geological Survey Bulletin No. 182 gives a description of this property.

Denver, Colo., Feb. 6. T. E. Sohwarz.

Water Hoisting in Mines.*

G. A. Burr, of Chihuahua, Mex., in discussing the paper of R. V. Norris in Transactions American Institute Mining Engineers on "Water Hoisting in the Pennsylvania Anthracite Region," and an abstract of which appeared in the Mining and Scientific Press, April 25 and May 2, 1903, says:

I regret that Mr. Norris did not give more attention to the hoisting of water in inclined shafts or slopes, the only slope mentioned being Hickory Ridge slope, No. 4, of the Union Coal Co. The surface arrangement, illustrated in the accompanying

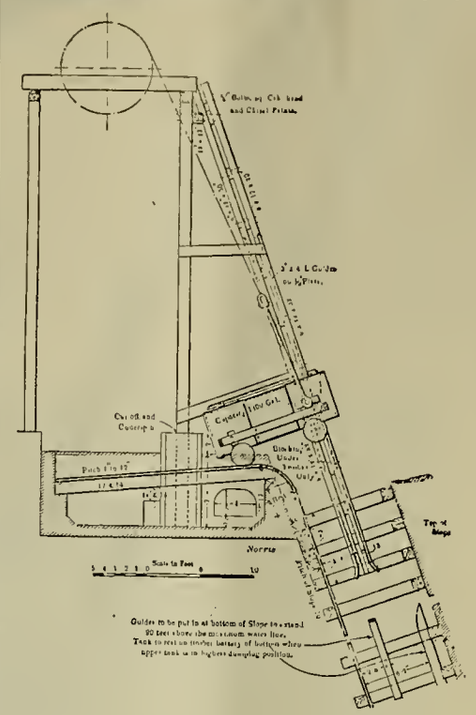

Fig. 1.

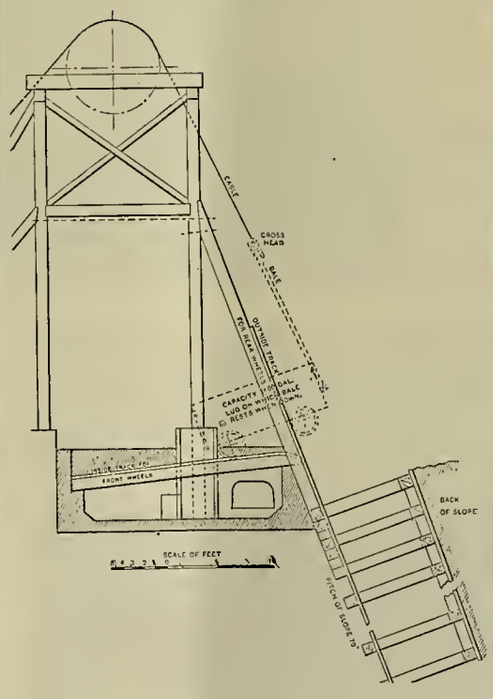

Fig. 2.

figure of his paper (Fig. 1), if not unpractical, is at least unscientific and cumbersome. It is my opinion that the back and side guides shown in this figure are not only unnecessary where rails are used as a track, but are unsafe, excepting in the case of a very firm hanging wall, or roof and sides of vein matter, having absolutely no tendency either to settle from the back or to squeeze from the sides, an effect which would inevitably force the guides out of alignment.

The accompanying illustration, Fig. 2, shows what I consider a better method of hoisting water than that described by Mr. Norris. This method is based on the general practice in metalliferous mines of the West, where skips are used in slopes; and, while it is not original with me, I have frequently used it with very satisfactory results for dumping both ore and water.

A special point to be observed is, as the stope approaches the vertical position, either the skip should be lengthened in order to have the center of gravity nearer the forward wheels, or the box should be depressed by raising the axles to its sides (instead of placing them underneath), in order to have the center of gravity nearer the rails, and thus avoid the danger of having the front wheels lift from the rails, which would result in derailing the skip.

I have been interested in Mr. Norris's paper on account of my experience in hoisting water in metalliferous mines, where the usually limited shaft area frequently precludes the hoisting of a sufficient number of sinker pumps to hoist the water.

The difficulty of solving this problem increases with the recession of the water level from the place of water discharge, and the consequent greater lift and increased duty required of the pumps. The use of tanks, or bailers, appears to me to afford a very practical solution of the problem, especially in cases where all of the pumps, including the "sinkers," have been drowned. Here the tanks can be swung into the hoisting compartments, the level of the water lowered, and the pumps recovered (provided, of course, that the tanks and the engines operating them are of sufficient capacity) without the inconvenience attending the tedious method of lowering steam and water columns, length by length, or of breaking joints and lowering the pumps.

For this method of hoisting water, where steam is used, it is needless to say that quick, direct-acting hoists, in competent hands, possess great advantages over those of the geared type.

*Trans. Amer. Inst. Min. Engrs.

Lead Bounty in Canada.

The regulations approved by the council governing the payment of the bounty on lead contained in lead-bearing ores mined in Canada are published in the Canada Gazette as follows:

That all producers of lead-bearing ores who desire to avail themselves of the bounty must notify the minister of their intention to make a claim under the Act, declaring the name of the mine producing the ore, its situation, and the names of the president, secretary and manager, as well as the name of the official authorized to make the claim.

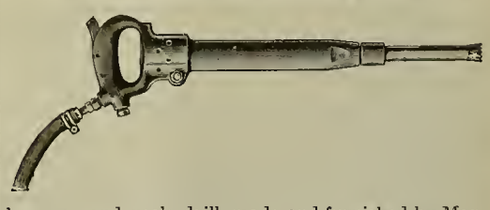
All claims must be substantiated on the oath of the manager of the mine. They may be made monthly, but no claim will be recognized unless in conformity with these regulations.

The smelting of all lead-bearing ores on which a claim for bounty is to be made shall be at all times under the supervision of an officer of the Department of Trade and Commerce, and this officer may at any time demand a floor sample of any ore delivered at the smelter for smelting purposes.

The books of any mining company coming under the Act are to be open at all times to the inspection of a supervising officer. The cost of such supervision is to be paid by the claimants and will be deducted pro rata from the bounty, according to the quantity smelted during the fiscal year.

Air Hammer Rock Drill.

Herewith is illustrated the "Little Wonder" air



hammer and rock drill, made and furnished by Martin Hardsoeg, Ottumwa, Iowa, who states that this machine drills a hole ⅞ or 1 inch 4 feet deep, and that "it will drill from 3 inches to 4 inches in quartz or granite, 6 inches to 8 inches in limestone, and 8 inches to 10 inches in sandstone or marble, in one minute." The machine weighs 17 pounds, and is stated to strike 2000 blows per minute. To operate it requires 14 cubic feet of air per minute at a pressure of from 80 to 100 pounds. As will be observed, it needs no column or tripod, but can be held in any position. Full detailed information will be furnished upon application to the manufacturer.

Phosphorescent Sphalerite.

To the Editor:—In your issue of January 23rd there is an article headed "Phosphoreseent Sphalerite," in the concluding part of which it is stated that phosphorescent sphalerite has seemingly been unobserved in this country.

About fourteen years ago I was examining a sample of ore from a lode in Graham county, Arizona. The character of the gangue I do not distinctly remember, but through it was thickly disseminated in fine grains a dark mineral that, so far as the unaided eye went, might be zinc blende or might be galena.

To determine the matter by streak I ran a knife

blade over the surface, and was surprised to see a vivid emanation of pale yellow light—and this in daylight—follow closely the path of the knife blade. Since that time I have scratched many samples carrying zinc blende, but have never met with another displaying this property of phosphorescence.

Dudleyville, Arizona, Jan. 30.

Working Low-Lying Gravel Deposits by the Hydraulic Elevator System.

Written for the MINING AND SCIENTIFIC PRESS by R. H. CAMPBELL.

The system of working gold gravels by hydraulic elevators was introduced in California about twenty years ago, since which time great improvements have been made in the construction of gravel elevators, so that it may no longer be considered an experiment, and those who have made a practical study of the system under varying conditions know just what can be accomplished with them.

Hydraulicking, although practiced extensively in California, and in other gold placer countries, for nearly fifty years, is still little understood, in its scientific aspects, even by those who have operated hydraulic mines for years. Water under pressure is the first requisite, and is indispensable in operating hydraulic mines. This acquired, the next most essential thing is to so adjust the plant as to get the greatest efficiency from the water. This important item is often overlooked and the duty of the water wasted or handicapped by loss in friction.

In elevating gravel there is a rule in adjusting the parts of an elevator by which the greatest efficiency may be obtained, viz., the throat to be twice the diameter of the nozzle, and the upcast double the diameter of the throat, but this rule can not always be adhered to, and deviation must be made in order to comply with existing conditions.

Accompanying this article are shown several illustrations of the elevator in sections, giants used in washing the gravel to the base of the elevator, and all of the machinery in practical operation. Fig. 1 and Fig. 2 show sectional side elevation of the latest improved Campbell hydraulic elevator, with manganese steel-lined throat, with rubber cushion to resist the extraordinary force of the gravel when entering the elevator. This cut shows the elevator inclined at the augle at which these elevators are usually set, although this position may be varied according to the conditions.

Fig. 3 shows a Simmons double-jointed ball-bearing giant, which is one of the favorite machines used by the hydraulic miners.

Fig. 4 shows giant, elevator and the pit produced by them in a two weeks' run at Nome, Alaska, on Anvil creek, bench No. 7, of the Miocene Ditch Co., and using about 300 miners' inches of water.

The capacity of an hydraulic elevator is governed by the volume of water under pressure and the height of the lift by the pressure in feet, or hydrostatic pressure at the nozzle in pounds. The load to be lifted is measured by the water which it is necessary to use in the pit in washing the gravel to the elevator, and constitutes 75% to 80% of the whole, leaving 20% to 25% for the solids. As small as this seems, it is often more gravel than the upper or outward sluice can care for or carry away. This is accounted for by the fact that the material entering the elevator is carried to the upper sluices so rapidly that the capacity of these sluices is often choked, even with its increased grade and large volume of water.

Much depends upon the character of the material to be elevated. If heavy or difficult to run, the elevator will have much greater advantage over the sluices, for the reason that the gravel is forced through the elevator, while in the sluice it can only be carried by the natural velocity of the water on sluice grade.

There is a limit to the height to which gravel can be lifted with profit. There have been several plants installed where a lift was 90 to 96 feet vertical, but 50 to 60 feet is considered the limit to which it can be done profitably. To lift to this height successfully requires a pressure of not less than 110 to 120 pounds at the nozzle, and under this pressure the wear is so severe that the very best manganese steel is required in the wearing parts to stand any length of time. From 25 to 45 feet lift is considered within the proper limit of profitable operation.

The capacity of hydraulic elevators depends, of course, upon the conditions, but in order that one may arrive at some approximate idea of the work which can be done with them, we have to say that a 20-inch elevator with 1000 inches of water under 250 feet head, elevating 42 feet vertically, and using 700 inches of water in the pit, would put through from 1500 to 2000 cubic yards of gravel per twenty-four hours.

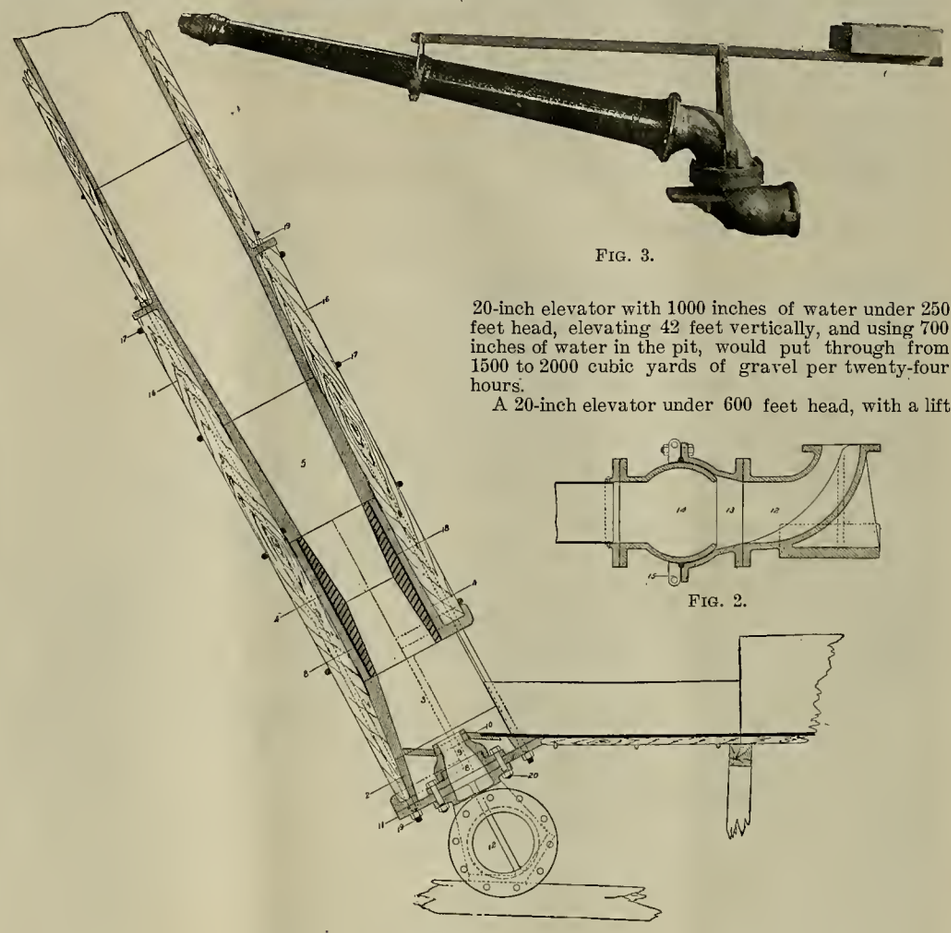

FIG. 3.

FIG. 1.

FIG. 2.

A 20-inch elevator under 600 feet head, with a lift of 90 feet vertically, with about 500 inches of water in the pit, would put through 1500 to 1800 cubic yards per twenty-four hours.

A 16-inch elevator under 350 feet head, and lifting to a vertical height of 48 feet, would put through from 1000 to 1200 cubic yards per twenty-four hours.

To determine exactly the machinery required for a plant of this kind, the following information should be given:

First—Diameter and length of supply pipe.

Second—Volume of supply water available in miners' inches or cubic feet.

Third—The pressure in pounds, or head in feet, vertically, of supply water.

Fourth—The height in feet, vertically, to which it is desired to lift the gravel.

Fifth—Amount of water flowing naturally into the pit.

Sixth—Whether it is determined to use giants for washing down the gravel, and, if they are to be used, if their water will be taken from the elevator supply pipe.

Seventh—If giants are used, their number should be stated, and size of nozzle aud head under which they will be operated.

Where the installation is of considerable magnitude and delays would prove serious, it is good practice to put in two elevators, side by side, so that in the event of being obliged to stop one from any cause the second may be at once started up.

FIG. 4.

THE Secretary of the Interior has requested the Civil Service Commission to hold an examination as soon as possible for constructing engineers in the U. S. Reclamation Service. This examination is to be similar to that held for consulting engineers last August. Competition is to be confined to men who have had responsible charge of large hydraulic works, such as dams and canals. The positions pay from $3600 to $4800 per anuum, and applications for particulars should be made to the Civil Service Commissiou at Washington.

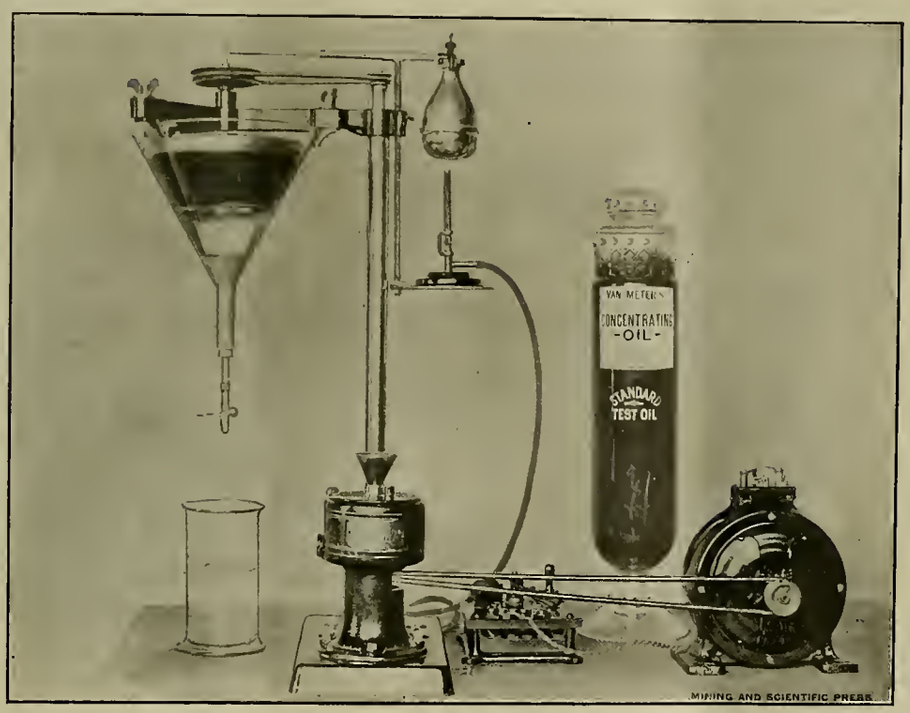
GUN METAL is an alloy of copper and tin in the proportion of 11 parts tin and 100 parts copper.

Laboratory Device.

The accompanying cut shows a laboratory device for determining the selective action of aluminated hydro-carbon oils, under different temperatures, in the concentration and separation of minerals by oil. The selective action of aluminated hydro-carbon oil for mineral particles of pulp varies, under different temperatures, and an oil may be compounded whose selective action for a certain mineral may be perfect at a fixed temperature, whereas with the same oil at a different temperature no selective action might take place. For instance, with an aluminated hydro-carbon oil compounded for the treatment of a certain silver-lead ore containing much zinc, at a temperature of 60° F. it possessed a strong selective action for all mineral particles of the ore, whereas at a temperature of 160° F. the zinc was unaffected. Working from these facts, it is claimed the zinc element can be sufficiently eliminated from many ores, producing a marketable product. This apparatus has been designed especially for assayers, laboratories and universities, for demonstrating the above principles. The manner in which the oil is kept at any temperature desired, the centrifugal action of the body of oil in producing the contact between the surface of oil and particles of mineral pulp, without agitation, have all been closely worked out.

The machine consists of an automatic working centrifugal, which separates the mineral from the oil. The glass spitzkasten or funnel contains a hollow aluminum cone, which revolves at a speed of about 200 revolutions per minute, being driven by a belt from the centrifugal separator below, connected with upright shaft inside of the support to which the spitzkasten is attached. The manner in which the lower and upper belts are connected to the shaft allows the operator to swing the spitzkasten while in operation to any position desired. The aluminum cone is used, says the inventor, for the reason that oil will not adhere to same when clean. The oil is kept at the different temperatures by steam generated in a retort filled with water and suspended over a gas jet attached to the framework holding the spitzkasten. From this retort a tube passes through the center of the upright shaft of cone and terminates within the aluminum cone.

Once the temperature of the oil has been raised above 100° F., the weight of the mineral entrapped by the oil tends to pull the oil to the bottom in sinkers. By the above device this is entirely eliminated, as the shape of the cone and spitzkasten brings into play centrifugal action, by which the mineral is held in suspension with the oil, leaving the gangne in the lower portion free from any sinkers. The gangue can be drawn off in a beaker while the apparatus is in operation by swinging to one side over the beaker, as shown in the cut. Then, by moving the spitzkasten over the centrifugal separator, the oil is allowed to pass into same, in which the separation of the mineral from the oil is effected. The apparatus is self-contained. Power may be applied by electric or other motor. A standard test oil has been compounded for use with this testing apparatus by J. W. Van Meter of San Francisco, Cal., inventor of the Van Meter system of concentration and separation of minerals by oil. All that is necessary in the testing of the ores is to find at what temperature the selective action for the desired mineral takes place. That having been determined, an oil is then compounded for use in the working plant which has the desired selective action at a normal temperature.



Laboratory Device for Testing Concentration of Ores by Oil.

Gold Mining in Southern Rhodesia.*

Written by THOMAS WARTH.

Rhodesia is comparatively a new and little known country; it will be years ere its geological formations can be located and its divisions definitely correlated. The high plateau, forming the watershed of the river systems and embracing the main area of the country, consists of granites and gneisses. A portion of it is overlaid by sandstones. It is worth noting that the country in the neighborhood of these schists is always more fertile and better wooded than that of the basement granite. This fact is a help to the gold miners, as it is in the schists that the auriferous veins usually occur. Considering the limit of the zone of their occurrence, it is possible some may be sedimentary and some igneous. These intrusive dikes in many cases appear to have been forced up before the matrix of the auriferous lodes was formed, as they have more often taken the place of the quartz than faulted it. The lodes usually follow conformably the foliations of the country, both horizontally and vertically, appearing at times to have pinched right out, and a few feet further on opening out wider than before. This makes not only the opening difficult, but the future of many mines speculative. It is generally admitted that the majority of the veins are fissures, although some, especially where the foot wall or hanging wall is granite, have been found too narrow at depth, and finally pinched out altogether.

The country is sometimes contorted. In one instance a shaft was put down vertically with the intention of cutting a reef dipping west, at 120 feet; the lode was cut through at 80 feet and then went down vertically, forming the hanging wall of the shaft. At 100 feet a drive was started south, following the strike of the reef which, after a series of corrugations, headed almost due east for a few feet and was then blocked out by country. Trenching on the surface, however, revealed what was presumably a continuation of the same reef some 600 feet back and striking in a normal direction. The enclosing country was extremely altered and was at times basaltic in appearance.

The colors are due to the presence of different sulphides, as of iron and copper; carbonates, such as azurite and malachite, which are widely distributed; oxides, etc. A great majority of the outcrops have the distinctive red-brown tinge, due to oxidation of iron pyrites. Last year a Bulawayo company, prospecting a reef for gold, struck a deposit of native copper within 60 feet of the surface, occurring in aborescent sheets between the jointing of the quartz. The Ayrshire mine in Mashonaland is an instance of gold occurring in diorite. The mine area embraces a huge intrusive dike in the granite with its longest diameter bearing east and west. The gold was first found in the diorite immediately next to a felspathic vein which appears to traverse the mass, but afterwards found disseminated throughout the entire dike. Just as the reefs differ in occurrence, nature and grade, so do they in width. Of quartz reefs, one in the Tai district, the Monarch, at one place is said to be 80 feet wide. The richness of the ore often varies in inverse ratio to the width of the vein, a reef showing a wide outcrop and giving a low assay value at surface, on proving at depth the vein stuff is less in quantity but of higher grade. As the reverse of this is also often true, it is seen that, from a speculative point of view, mining in Rhodesia is in direct contrast to the banket mining of the Transvaal, where the gold is so evenly distributed that the value of the gold contents of a mine area may often be approximately determined before a shaft has been put down. Many outcrops show visible gold, especially when by the oxidation or dissolution of the mineral constituents the stone has become honeycombed; on washing it fine grains of gold are generally discernible. On crushing, this class of ore is often found to be deceptive, the whole of the gold contents being visible and the stone containing none of the metal in combination. At the same time, Rhodesia has furnished hundreds of rich specimens of nugget gold. It was this class of outcrop which attracted the ancients.

The crystalline rocks and schistose bands containing the auriferous veins of the high plateau forming the backbone of Southern Rhodesia may be regarded as a coast, bounded on its northern, western and southern shores by sedimentary strata. On the south these are shallow and of small area, appearing to fill the hollows in, and lying unconformably on the metamorphic rocks; but on the west and north they are of greater extent.

Some 250 miles northwest of Bulawayo, and between the Gwaai river on the east and the Kalahari desert on the west, are the Waukie coalfields; to the east, between the Gwaai and Saugli rivers are the carboniferous areas of Luba, Sengwe and Sesani. Here seams of workable coal in shales and sandstones, with occasional ironstone bands, have been found, and are to-day being developed with all possible speed. The coal measures appear to lie unconformably on metamorphic rocks, and extend northward beyond the Zambesi river, having a gentle dip south to southwest. These coalfields lie close to the Victoria falls. There is no native timber, above a few inches in diameter, within 80 miles of Wankie; but the railway will reach the field this year.

The first essential for the successful development of Rhodesia is a return of confidence by the investing public. The country is still undeveloped and gives indications of rich deposits of minerals. Other requirements are a plentiful supply of unskilled labor, reasonable and reliable transport and cheap fuel.

The tendency has been for wages to increase, and 35s to £2 per month may be taken as an average figure for good drill boys. Surface boys get from 5s to 15s a month less than drill boys, but boss, or special boys, are paid up to £2 10s per month. A good white miner or mechanic gets 20s or more per day.

The principal Rhodesian woods used for mining are the mapaani, knobbesdorn and native mahogany; of these, knobbesdorn is the toughest and most lasting. For stations, and lining the bins at the different leads, Oregon pine may be used. Cordwood, for firing, should not be under 3 inches diameter; may be had from 15s to 20s a cord. A cord of mapaani is roughly equal to from 10 to 15 cwts. of coal for generating steam.

Up to the present, owing to the heavy railway rates on coal, which has to be carried about 1000 miles, as from the Transvaal or Natal, it has been customary to burn wood for charcoal for the blacksmith's forge and assayer's furnaces. All timber, native or imported, which is in contact with the ground, excepting timber in the mine, should be creosoted or well tarred, as a safeguard against the ravages of white ants.

In many districts in Rhodesia there is running water all the year round, in others the construction of large dams will be a necessity, for though the rainfall is sufficient to supply water for all purposes, it only occurs during the wet season. As a dam of any extent takes some time to build, this is one of the first problems the mining engineer should solve, that the building of the dam may run concurrently with his development. The management of the Eagle Vulture mine, in the Gwanda district, are building a dam with a capacity of 40,000,000 gallons.

The experiment of a dry crushing plant has been tried at the Wanderer mine in the Selukwe district, and is successful; and their plant, which will treat 12,000 tons a month, shows a good profit on a 4½ dwt. ore. This will probably be the forerunner of many similar plants in the country where the lack of water has been the chief drawback to profitable exploitation.

The following rates have recently been given out as specimens of present day rates on Rhodesian railways: Natives, 0.166d per mile; hay, 0.25d per ton mile; farm produce, 0.5d per ton mile; concentrates, 0.75d per ton mile. The Wankie coal, which is already being used on the section of railway between Salisbury and Machurdi, is proposed to be carried at a uniform rate of 1.5d per ton mile north of Bulawayo, and a through rate of 0.5d per ton mile south of that town. Its estimated cost is about 30s per ton delivered to the mining districts.

* Abstract of Trans. South Staffordshire and East Worcestershire Inst. Min. Eng.

The Geology and Copper Deposits of Bisbee, Arizona.*

NUMBER II.

Written by F. L. RANSOME.

POST-CARBONIFEROUS FAULTS AND INTRUSIONS.—At some time during the interval between the close of the Carboniferous aud the opening of the Cretaceous, the long-continued subsidence and sedimentation of the region were interrupted by extensive faulting, probably connected with uplift. The faults were mostly of the normal type, but there was also some reversed or overthrust faulting that may have been slightly later than the prevalent normal faulting. Following the faulting came intrusions of granitic magma, which solidified as granite, granite-porphyry and rhyolite. These intrusions took the form of dikes following fault fissures, of sills injected between sedimeutary beds, and of irregular stock-like masses. The dikes are well shown along the southwest face of Escabrosa ridge, west of Bisbee. The larger intrusions are exemplified by the granitic mass of Juniper flat, which is enclosed in Pinal schists, and by the smaller body of mineralized and altered porphyry forming Sacramento hill, just southeast of Bisbee, and intrusive into Pinal schists and Paleozoic limestoues. The latter mass is of particular significance from its connection with the principal copper deposits of the district. The intrusion of the porphyry of Sacramento hill was accompanied and followed by contact metamorphism involving the introduction of much disseminated iron pyrite into the adjacent Paleozoic limestones and the local transformation of the latter into fine-grained aggregates of calcite, tremolite, wollastonite, garnet, chlorite and quartz. The metamorphic minerals, with the exception of the pyrite, are uever conspicuously developed, and can usually be identified only in microscopic sections.

After the intrusion of the granite-porphyry, the region was eroded until the opening of Cretaceous time. It is probable that the primary mineralization of the district followed closely upon the eruption of the porphyry, and thus dates from early Mesozoic time.

THE MESOZOIC SEDIMENTARY SERIES.—At the beginning of the Cretaceous the regiou again begau to subside, and a couglomerate was deposited by the advaucing sea over the eroded surface of the pre-Cambrian and Paleozoic rocks, with their intruded masses of porphyry. This conglomerate is the basal member of the Bisbee group, an assemblage of Cretaceous strata comprising four formations. These are in ascending order (1) the Glance conglomerate, (2) the Morita formation, (3) the Mural limestone aud (4) the Cintura formation.

In places the Glance conglomerate was laid down to a uniform thickness of about 75 feet over an even surface, but elsewhere it is fouud filling hollows in a pre-Cretaceous hilly topography aud attaining a local thickuess of over 500 feet. The pebbles are composed chiefly of schist, although those of limestoue and granite-porphyry are not entirely absent. With the continued subsidence of the region, the Morita formation, comprisiug about 1800 feet of unfossiliferous sandstones aud shales, with occasional lenscs of saudy limestone, accumulated above the basal couglomerate. Couformably overlyiug these is the Mural limestone, about 650 feet in thickness, containing abundant fossils characteristic of the Comanche division of the Cretaceous. Most of these limestones, particularly the lower beds, are thiubedded and impure; but hard, gray massive beds, aggregating 40 feet in thickness, occur uear the middle of the formation aud form a cliff that is a conspicuous topographic feature of the hills uorth and east of Bisbee. The Mural limestone is conformably overlain by the Cintura formation more than 2000 fect in thickness and consisting of alternate sandstones and shales, much like those occurring iu the Morita formation. These Cintura beds of the Bisbee group are the youngest stratified rocks exposed in the Bisbee quadrangle. As their upper surface is everywhere one of erosion, their original thickness is unknown. The foregoiug Cretaceous strata were first described by Dumble and by him called the "Bisbee beds."

POST-CRETACEOUS DEFORMATION AND INTRUSIONS.—The beds of the Bisbee group have beeu deformed by folding aud faulting and are cut by a few small dikes of diorite-porphyry, excmplified by the dike at the Glance mine. The folds are generally open, dips of more than 20° being rather exceptional. The general strike is N.W.–S.E., and the prevailing dip northeast. About 7 miles southeast of Bisbee, however, where Paleozoic beds have been thrust by faulting over the Cretaceous, the latter have been turned up steeply aud are in places nearly vertical. East of Bisbee the faults are normal, but southeast of Mule Pass gulch faults of the reversed or overthrust type predomiuate. The most striking of these latter faults is that exposed at Gold Hill, 5 miles southeast of Bisbee. The summit of this hill is composed of Paleozoic limestones which have been thrust from the southwest over the beds of the Cretaceous Bisbee group for a distance of at least 2 miles.

* Abstract Trans. Amer. Inst. Min. Eng.

As Tertiary sediments are absent in the Bisbee region, this period was probably marked by the deformation of the Cretaceous and older rocks and by erosion.

THE QUATERNARY VALLEY DEPOSITS.—The Quaternary is represented by unconsolidated gravelly deposits flooring the broad valleys that surround the Mule mountains on the west, south and east. These are in the main fluviatile wash, with possibly some finer lacustrine beds at a distance from the mountains.

ECONOMIC GEOLOGY. — Prior to the year 1880, Bisbee was an unimportant lead camp, a single furnace being then in operation upon cerussite mined from the Hendricks claim, close to the town. The copper ore of the Copper Queen mine was discovered early in this year and was profitably exploited until 1884. This ore was free from sulphur and had an average tenor of 23% of copper. It was treated in two 36-inch furnaces, which, in spite of their small size, were able, with wood as a fuel, to turn out about 500,000 pounds a month. In 1882 the men composing the present Copper Queen Con. M. Co. bought the Atlauta claim, near the original discovery, and began prospecting.

In 1884 the Copper Queeu ore body, which had been worked for 300 feet down an incline, was exhausted. The outlook was gloomy and work was almost abandoned, when a secoud ore body was simultaneously discovered from the original Copper Queen incline and from the Atlanta workings. In order to avoid legal complications, the two companies combiued as the Copper Queen Con. M. Co., which gradually absorbed the neighboriug properties by purchase. In 1886 the old smelting plant became inadequate and was rebuilt. Greater economy was necessary, as the average tcnor of the ore in copper had fallen to about 8%, and the price of copper had also notably declined.

Shortly after 1890, the completely oxidized ores showed signs of failing. But in 1893 the works were remodeled by the introduction of converters, and sulphide aud oxide ores have since that time been successfully worked together by the matte process. The iutroduction of these couverters was due to James Douglas and marked the beginning of a new epoch in the smelting of copper ores in Arizoua.

Up to the end of 1902 practically all of the copper from Bisbee was the product of the connected group of miues owned by the Copper Queen Con. M. Co. Recently, however, extensive ore bodies have beeu opened up in the Calumet & Arizona mine, and in the latter part of December, 1902, this company was turning out from thirty to forty tous of copper per day from its new smelter at Douglas.

The town of Douglas, situated in the middle of Sulphur Spring valley, on the Interuational boundary, has sprung up with remarkable rapidity during the past year. Its growth is due to the erection herc of the new smelters for the Copper Queeu and Calumet & Arizona companies and to the fact that it is the junction point of the newly completed El Paso & Southwesteru Railroad with the Nacosari Railroad into Mexico. It will uudoubtedly become au important smelting point, not only for the Bisbee ores, but for those from Mexico.

PRODUCTION.—From August, 1880, to the end of 1902, the total output of the Copper Queen Con. M. Co. was 378,047,210 pouuds of copper. The product of the receutly opened Calumet & Arizona mine within this period is 2,066,647 pounds; so that the total recorded productiou of the district is 380,113,857 pounds of copper. The maximum output was in 1901, when the Copper Queen mines produced 39,781,333 pouuds of copper.

PRESENT UNDERGROUND DEVELOPMENT.—The Bisbee quadrangle contains two large productive mines —the Copper Queen and the Calumet & Arizona. In addition to these are a few undeveloped mines that have produced comparatively small quantities of good ore, and a number of prospects, ranging from shallow pits to shafts several hundred feet deep, connected with extensive systems of drifts.

The Copper Queen mine comprises a maze of workings connecting with the surface through four working shafts and several less used openings. The area, more or less thoroughly intersected by drifts and crosscuts, covers nearly half a square mile, where the extreme vertical range of underground exploration is about 950 feet. The workings are practically all in Carboniferous limestone. From 650 to 700 tons of ore are raised per day, chiefly through the Spray, Holbrook and Czar shafts.

The underground development of the Calumet & Arizoua mine is confined to the Irish Mag claim. The mine is operated through the Irish Mag shaft, 1200 feet in depth, situated 900 feet S.–S.E. of the Spray shaft and about three-quarters of a mile in the same direction from Bisbee. The workings are all in Carboniferous limestone. Stoping in this mine began iu the autumn of 1902, and about 300 tons of ore were raised per day before the end of the year.

GENERAL CHARACTER OF MINERALIZATION.—The Bisbee quadrangle owes its economic importance exclusively to the occurrence of ores of copper. The unimportant deposit of lead carbonate in Hendricks gulch, which was the first discovery in the district, is still being worked in a small way, and the Easter Sunday mine has supplied the siliceous gold ore used in the Copper Queen smelter for converter lining; but these, so far as known, are the only instances in the quadrangle of ores commercially exploited for other metals than copper.

For a district which has produced nearly 400,000,000 pounds of copper, the Bisbee quadraugle, iu spite of the general bareness of its rocky slopes, exhibits little superficial evidence of its mineral wealth. The porphyry mass of Sacramento Hill, southeast of Bisbee, and the schists that partly enclose it, show considerable alteration and contain abundant disseminated pyrite, which by oxidation imparts a rusty stain to the rocks; but, so far as known, no deposits of value occur wholly within these discolored rocks. Along the Dividend fault in Bisbee outcrop some dark rusty masses composed principally of limonite. Similar ferruginous ledges occur in Hendricks gulch, on Queen hill and in the limestone south of Bisbee. Experience has shown that such limonitic croppings, although rarely exhibiting superficial indications of the presence of copper, are nevertheless frequently associated with an underlying ore body. They evidently result from the oxidation of pyrite, the less soluble iron oxide and some silica remaining near the surface, while such copper ore as was originally present has been carried down by percolating solutions and redeposited at lower levels. These bodies of limonite, when not too siliceous, are the best surface indications of ore that the district affords. Many of the most important ore bodies, on the other hand, would have remained undiscovered were superficial phenomena alone relied upon to suggest exploration.

Although the rocks of the quadrangle are seamed with faults and dikes, none of the workable ore bodies occur as lodes or fissure veins. With a few exceptious they are irregular replacements of limestone. Originally pyritic, and containing probably subordinate amounts of chalcopyrite, they owe their present value to secondary coucentrations effected by processes of sulphide eurichment and of oxidation.

OCCURRENCE OF THE ORES.—The principal bodies of copper ore all lie south cf the town of Bisbee, within a radius of a mile. They occur in Carboniferous limestone, on the southwest side of a great fault (the Dividend fault), and closely associated with an intrusive mass of granite-porphyry. In the absence of the geological map and sectious, the structural relations may perhaps be most clearly presented by a homely illustration: If the half of a broken saucer be placed flat on the table with the fractured edge lying about W.N.W., and if the back of a book be laid against this edge, we shall have a rough illustration of the geological structure near the town of Bisbee. The saucer represents the synclinal attitude of the Paleozoic beds, from the upper Carboniferous Naco limestoue down to and including the Cambrian Bolsa quartzite. The broken edge of the saucer is the great fault, while the book is pre-Cambriau Pinal schist, against which Naco limestouc has been dropped by this fault, with a throw of more than 1500 feet.

(TO BE CONTINUED.)

An Important Matter.

TO THE EDITOR:—I have read with much interest the article, "An Important Verdict," in your issue of the 6th inst. The ground is well covered by the article except that no explanation is offered as to why the engineer lost control of his engine. This is a vital point to be considered in trying to prevent such lamentable occurrences. I was once a witness of a precisely similar accident. Oue of my engineers was hoisting a car, and when it reached the collar of the shaft he attempted to shut off the steam, but found he could not do so. We were equipped with three brakes—one ou the main shaft of the hoist and one on each drum. These were applied instantly and stopped the cage before it reached the sheave. I had the valve opened and found to my astonishment that, although it was one of the best valves in use, it had failed at a critical time from this fault in construction. The valve proper was fastened to the round valve stem by a metal pin only one-eighth of an inch in diameter. This pin had broken and the stem would turn without closing the valvc. I ordered a uew valve made with the valve stem square at the point where the valve proper was fastened to it, the valve proper being made with a square hole also. This prevented the possibility of such an accident occurring again, as even if the pin would break the square valve stem would prevent its turning.

As to the fourth count, it was the engineer's business to know, and not take for granted, that his brakes were in working order.

Strong landing chairs should always be used, that open at the rising of the cage and close automatically. This might have lessened the fatalities. The extra man is needed at the collar of the shaft and not at the engine. All possible precautions should be taken where life is involved, and in my opinion all hoists should be equipped with valves as above described. It would greatly lessen the danger of such terrible accidents. ANDREW ROCCA.

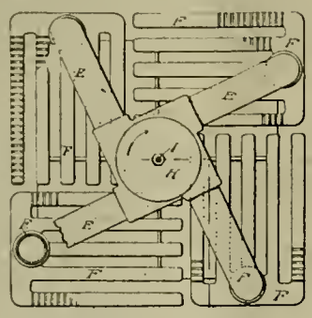
Middletown, Cal.

Mining and Metallurgical Patents.

PATENTS ISSUED FEBRUARY 2, 1904.

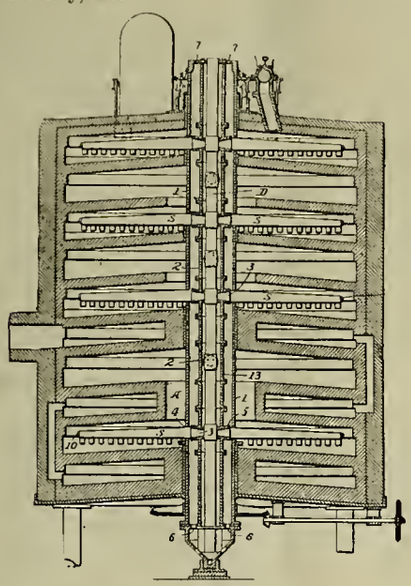
Specially Reported and Illustrated for the MINING AND SCIENTIFIC PRESS.

HYDROCARBON BURNER.—No. 751,066; W. E. Gibbs, Fanwood, N. J.



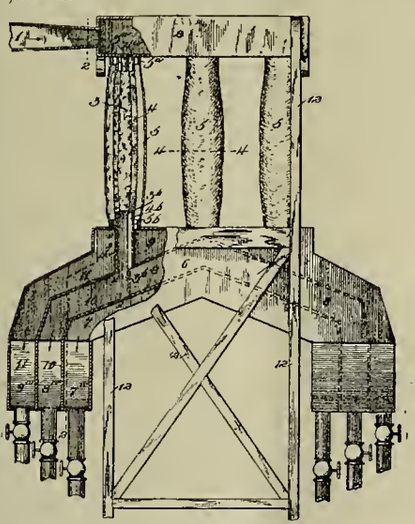
In hydrocarbon burner, combination of burner tubes having common distributing chamber, distributing pipes connecting chamber with outer portions of burner tubes, spraying and vapor driving device in chamber and means for supplying fuel and air to chamber.

ROASTING FURNACE.—No. 750,877; A. R. Meyer, Kansas City, Mo.



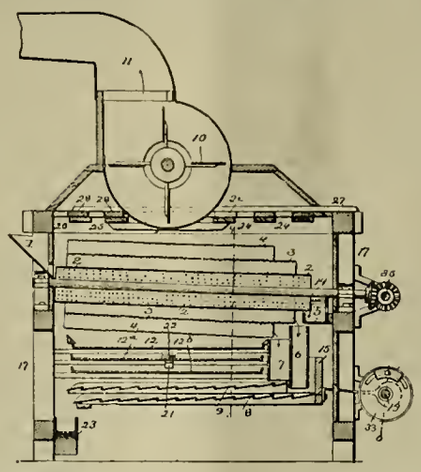
Shaft having inner and outer concentric sections with coinciding sockets, combined with radial arms having stems fitting coinciding sockets, and means for retaining parts in connection.

CONCENTRATOR.—No. 751,424; H. Wismeyer, Emporia, Kans.



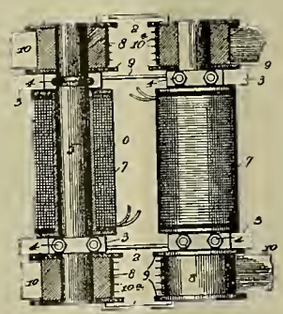
Concentrator comprising distributing chamber, separator and grader having series of compartments and pockets, series of conductors arranged intermediately of distributor and grader and composed of series of concentric tubes which are permeable to air and graded in mesh, inner tube alone communicating with distributer and other tubes being closed at top and communicating separately with respective compartments of grader.

COMBINED GOLD SEPARATOR AND AMALGAMATOR.—No. 751,425; H. Wismeyer, Emporia, Kans.



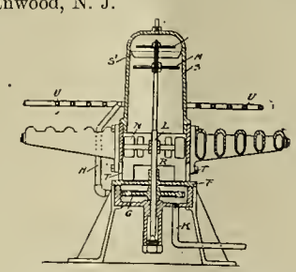
Combined gold separator and amalgamator comprising rotary separator proper consisting of series of graded perforated concentric cylinders, like series of conductors into which cylinders respectively discharge, two riffle plates arranged in lower portion of machine and receiving material from two of conductors, series of inclined amalgamating plates arranged at angle to each other and interposed between separator and riffle plates and supported in same reciprocable frame with latter, and fan located above separator.

ELECTRO-MAGNETIC ORE SEPARATOR.—No. 751,100; E. M. Oviatt and A. Dean, Denver, Colo.



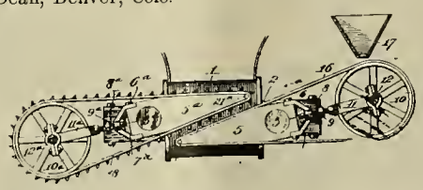
Magnetic ore separator comprising pair of electromagnets, each having north and south pole and fixed coil, each pole of each magnet being arranged adjacent to pole of opposite polarity of other magnet, producing induced current through both magnets, plurality of revoluble pole members within magnetic circuit of magnets, and means rotating members.

HYDROCARBON BURNER.—No. 750,962; W. E. Gibbs, Fanwood, N. J.



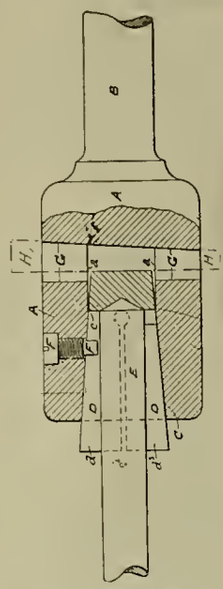
In hydrocarbon burner, combination common distributing chamber, of burner tubes surrounding and adapted to heat chamber, of means for supplying air and hydrocarbon spray or vapor to chamber, fan located in chamber, and means independent of air supply for driving fan at high velocity.

ELECTROMAGNETIC ORE SEPARATOR.—No. 751,150; A. Dean, Denver, Colo.



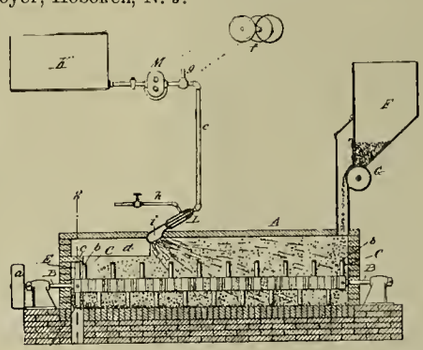
In electromagnetic ore separator, combination of magnet coil, core, cranks rotatively seated in core and having outwardly extending arms, tapering pole members mounted on crank arms, and means arranged to traverse one of pole members and adapted to receive material subject to magnetic attraction passed between pole members.

CHUCK FOR ROCK DRILLING MACHINES.—No. 751,311; L. Leigh, Jr., Luipaardsvlei, Transvaal.



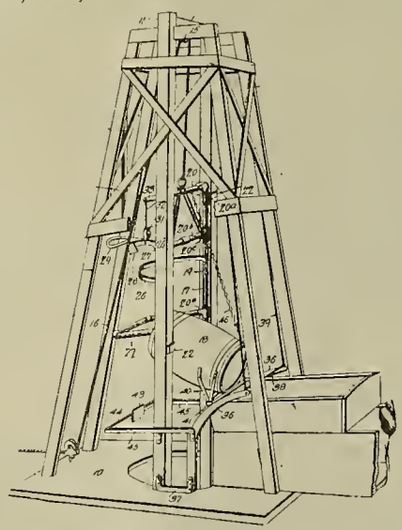
Rock drill chuck comprising head or main portion constructed with internal longitudinally tapered cavity and correspondingly tapered bush split for portion of its length to form plurality of compressible jaws constructed to embrace shank of drill between jaws, and made solid or closed at inner and smaller end to form stop or abutment.

PROCESS OF PREPARING PULVERULENT MATERIALS FOR MOLDING OR BRIQUETTING.—No. 751,134; R. A. Zwoyer, Hoboken, N. J.



Process of mixing binder with pulverulent material, consisting in adding binder in finely divided form to such material when particles of material are maintained in suspended or separated condition, and passing binder in finely divided form through chamber.

DUMPING ELEVATOR. — No. 751,225; F. B. Van Cleave, Echo, Or.



In dumping elevator, combination with supporting frame and tilting bucket, of locking mechanism for bucket, tripping mechanism for locking mechanism, guides with which bucket coacts when it is tilted, and actuator for tripping mechanism having arm secured to guides and to supporting frame.

Mining Summary.

SPECIALLY COMPILED AND REPORTED FOR THE MINING AND SCIENTIFIC PRESS.

ALASKA.

A. K. Beatson, part owner of the Bonanza group of claims on Latouche island, reports development work being increased, says the Valdez News. Regular ore shipments are going out. Shipment of 100 tons in December netted $1607.15. The ore runs 13% copper, with a little silver and gold, and $3 per ton freight is paid. A tunnel is being run into the ledge at greater depth than the previous tunnels.

ARIZONA.

Cochise County.

The Wolverine & Arizona, Calumet & Bisbee, Calumet & Cochise and Portage Lake & Bisbee companies, operating in Warren district, near Bisbee, have all bought diamond drill outfits for use in developing their claims. Heretofore work has been confined to sinking shafts and opening drifts.

Graham County.

B. Crawford and D. Awalt last week bonded the W. T. Kinsey and E. E. Frye group of four claims at head of Chase creek, near Clifton. Assays of samples taken across the 4-foot vein are said to show three ounces gold per ton, besides some copper and silver. It is intended to start development work this week, contract having been let for continuing the shaft and beginning a tunnel. The latter is on one end of the group and the shaft on the other. The tunnel will go in on the ore and follow it to the shaft.

Work has been started on a 4-foot vein of gold crossing the bottom of a 60-foot shaft on the Katydid group of claims, next to Lime Point, below Morenci. The group contains eight claims. It is owned by D. P. Marshall, C. Henry, Stevens & Shade, G. Depee and H. Quinn, of Clifton. There are several hundred feet of work on the claims in tunnels and shafts. The 4-foot vein is said to assay $16. The group has a millsite on Chase creek.

Mohave County.

The Security M. & Dev. Co. (the Elkhart M. Co.) at Chloride, has been reorganized under the name of the Arizona Bullion M. Co. It is the intention of the company to sink the main shaft of the mine to depth of at least 1000 feet.

The Suncloud M. Co, will have its mill in operation on the lower Sandy river, south of Kingman, next month. The mill will he of 10-stamp capacity. The mine is near the stream from which a supply of water for milling purposes can he obtained.

Yavapai County.

Superintendent J. T. McLaughlin of Jerome of the Braganza G. M. Co. says they will remodel the 20-stamp mill and put in additional machinery.——E. L. Bowman of Prescott, president of the Rainbow G. M. Co., says they will increase development work and build a mill at the mine next summer.

B. Blanchard, manager of the American C. Co. Iron King group at Blanchard, says work is progressing and the equipment is being improved. Four steel cyaniding tanks were received last week and are being set up. Each tank will have capacity of sixty tons. He says the copper sulphide ore in shaft No. 5 is holding out. It carries values in gold and silver also. The shaft is down 175 feet.

Yuma County.

O. E. Rumer says he has opened a body of ore in five different places on his Bill Bear group at the old Desert mine, near Harrisburg. Water is found at depth of 50 feet and wood can be delivered at the mine for $3.50 per cord. He expects to repair his 10-stamp mill.——Manager Lind has men working his California group, 6 miles north from the Desert mine.——H. Griffin is working his holdings adjoining the California group, and is sinking a 100-foot shaft on a ledge which crops the entire length of four locations. Griffin has eight claims in this group.

CALIFORNIA.

Amador County.

Near Volcano, Bradshaw, Santirfo & Baroni have leased a strip of ground containing four acres, on the Elephant placer. They expect to operate with one hydraulic pipe, equipped with a 6-inch nozzle. The gravel ranges in depth from 1 to 5 feet. ——Marsino Bros. are working forty-five acres of ground on edge of town of Volcano, in what is known as the "lava beds." These lava beds are areas of gravel covered with a heavy flow of lava, says the Ledger. Owing to the lava covering, it is impossible to work with the hydraulic process. The gravel is streaked with thin strata of cement. This latter contains pay, and in the open air slakes so that washing is possihle. Sometimes, however, it is stored and crushed in a stamp mill and the gold saved on plates. They have a 200-foot tunnel on their ground and are running crosscuts. Owing to the lava covering, no timbering is used in the tunnels, and little timher is used in mining the gravel.——The Christenson claim has been sold to Grillo Bros. and men are driving the 500-foot tunnel ahead. This property is equipped with Huntington mill, and has a water right. In addition to these placers the Grillos own the Columhus quartz claim, 3½ miles south of Volcano, which they will develop in the spring. A 5-stamp mill was huilt hy the former owners. However, the only development done so far is a 240-foot tunnel on the ledge, which opens it at depth of 90 feet.——Kimhall Bros. are operating the Deadwood mine, 1 mile north of Defender. They are working it hy shaft, which is down 60 feet. At this point water was struck and a boiler, pump and small hoist are heing set up, which will enahle them to sink to depth of 200 feet. It is expected sinking will resume this week. The ledge is 12 inches wide. A mill run of nineteen tons gave cleanup of $32 per ton.

Superintendent W. R. Thomas reports work progressing at the Central Eureka mine at Sutter Creek. A contract has heen let to sink the shaft another 100 feet and 5 feet is heing made per day. One skip is kept at the disposal of the men sinking the shaft all the time, hut the forty stamps of the mill are kept dropping on ore hrought up hy the other skip.

Calaveras County.

At the Royal mines at Hodson the strike was declared off. Superintendent Kemp Van Ee says he has full force at work with 100 stamps dropping, and the entire 120 stamps will be at work this week.——At the Mountain King, adjoining the Royal mine, work has been stopped temporarily. The shaft is an incline 200 feet deep.

In the Kaiser & Maguire mine, on French hill, near Mokelumne Hill, a four-ounce nugget of gold was reported found last week. This mine is contiguous to the former placer diggings.

The work of clearing out the ditch and repairing the mill at the Jones mine, south of Angels, has hegun. In conjunction with the Allison group the Jones has heen bonded to J. Cameron and T. Kerns of Spokane, Wash. The improvements on the Jones consist of a 40-stamp mill, a double compartment shaft 660 feet deep, hoisting works and hlacksmith shop, while on the Allison group there are two tunnels, 150 and 200 feet each, hesides a number of open cuts. The bond is for two years and a half. The mine is near the Stanislaus river, below Melones.

At the San Domingo mine, near Angels, a rotary gravel mill is heing placed. B. Thompson is president of the company. ——At Vallecito G. Mienecke has a 400-foot tunnel in his gravel claim and expects to tap the channel this month.——It is reported work at the Duchess mine, near Vallecito, will soon he restarted.

At the asbestos mine on west side of Bear mountain, near Copperopolis, being operated and owned by a San Francisco company, work is progressing. Ten men are at work, and asbestos is heing taken out.

Work is resumed at the Garihaldi mine near San Andreas.——The Lloyd mine at Central hill, near San Andreas, is reported ready to start up again.

Work at the Old Stiff hydraulic mine at Vallecito is going ahead. Piping is well into the main channel.——Work on the Forty-Nine placer mine at Douglas Flat is progressing under Superintendent Evans. Considerable development work has heen done.

F. J. Juchter has honded the Chris Anderson placer mine, on the Central hill blue gravel channel, near San Andreas, near the Marshall, Hedrick, Johnston and Nelson placer mines. The Chris Anderson mine has given values on the rim, but the heavy inflow of water prevented sinking to bedrock in the channel. The shaft is 85 feet deep; this will he timhered, pumps put in and then sinking will he resumed.

There are 210 stamps dropping at the mines and mills in and around Angels.

A heavier pump has been placed at the Lloyd gravel mine at Central hill, near San Andreas, and other machinery will also he put in.

The Del Monte M. Co. of Jackson, operating the Del Monte mine, near Railroad Flat, after having for some time partially suspended operations, has resumed full operations, says Superintendent G. I. Wright. A 1000-foot crosscut tunnel was started to reach the ore shoot, and 850 feet of this driven. The remaining 150 feet will he driven.

The Gertrude M. Co. of Angels, J. R. Dorroh president and W. Morehead vice-president and manager, with A. G. Madson, M. H. Manuel, O. Dolling, W. N. Garland and W. H. Thomas as directors, has heen organized for working the Demarest mine, on Cherokee creek, near Fourth Crossing. The improvements consist of a 5-stamp mill, a shaft 650 feet deep with crosscuts and drifts at the various levels, hlacksmith shop, hoisting engine and cahle sufficient to reach 1000 feet depth, skip and other machinery. Free water is to he had the year round; the land comprises 340 acres.

Inyo County.

Development of the Sacramento mine, near Bishop, is under way, J. W. & C. Brown, I. E. Dewitt and T. W. Key working it under lease. They have a 3-foot face of ore. J. W. Brown proposes to work the ore in his mill.

Kern County.

(Special Correspondence).—Conditions at Randsburg are improving and the camp is recovering from the fire and the strike of June last. For several months the mills were closed. The town has heen largely rehuilt.

The Yellow Aster M. Co. is taking out more ore than ever hefore and its two mills of 100 and 30 stamps, respectively, are crushing 500 tons of ore daily. There is a total of 15 miles of underground workings in the mine and quarries show on the surface of the mountain up to its summit. The company recently acquired property on their western extension for $60,000.

There are other mills in the district, a 2-stamp custom mill operated hy C. H. Snow; a 10-stamp mill owned hy the Butte Co., of which P. H. McMahon is superintendent. Neither of these is operating at present, nor is the Black Hawk, a 10-stamp mill, owned hy T. W. Atkinson, who owns the Sunshine mine, a producer of Stringer district.

At Johanneshurg there are three 10-stamp mills—the Red Dog, owned hy the Stanford M. & R. Works, with F. A. Mann in charge; the Phœnix, with E. Hammond in charge, and the Pinmore.

In the Stringer district, 2 miles south of and paralleling the Randsburg district proper, is the Baltic Co.'s mill, operated by C. H. Wynn, manager and part owner. This district has been and still is a good producer at shallow depths. This section has always paid its way, unassisted by outside capital, and there has heen as yet no deep development. Even the Yellow Aster, which has operated on a high hill, has not really attained depth. The development of the Randsburg district is as yet in its incipiency, and it offers opportunities for capital to show that there are deep mines to he made here.

Randshurg, Feb. 9.

L. D. Daves and J. Peterson have leased the Red Dirt mine, near Randsburg, and have begun work.——Nebeker & Buck are leasing on the Bully Boy claim, east of the G. B. and adjoining the Sisters claim.——Bouchard & Thompson have a lease on the Banner.

The Standard Oil Co. pipe line from Kern river to Point Richmond is again pumping oil from the Kern River field.

Nevada County.

Superintendent W. Graham of the Shady Creek dredge claim at the Phelan ranch, near Nevada City, says operations are being resumed after a shut-down of two months hecause of lack of water. This property is mainly owned by P. C. Drescher of Sacramento. Present arrangements for ohtaining a water supply are not satisfactory. Survey has been made for a new 7-mile ditch from Columbia hill to the mine, and they will build it in the spring. It will insure abundance of water the year round. The elevator process is used at this mine. —— Superintendent C. L. Miller of the Brophy claim, where work was recently suspended before bedrock was reached, says he expects to start up again this month. F. Hall of San Francisco is manager. The mine is equipped with a centrifugal gravel pump.

A. H. Tickell of Nevada City has bonded the Crumhecker mine in Washington district, for Eastern men. The company has hegun operations.

The Quartz Quarry M. Co., having a hond on the Junction mine, near North San Juan, has operations temporarily suspended. When work is resumed attention will first be given to sinking the main shaft to bring it down to water level.

The Round Mountain Champion mine, on the lower Bloomfield road, near Nevada City, has heen bonded for two years hy H. Huckins and A. Scribbens. Work will be started this month.

It is reported the Bonnie B. mine, near Grass Valley, will be equipped with a 20-stamp mill.

The Round Mountain mine and extension, 4 miles above Nevada City, has been honded hy R., H. and S. Huckins and A. Scrivens for $8000. The mine is on the Rock Creek road and has a shaft 500 feet from the Rock Creek hridge. It is 60 feet deep and shows a 2-foot ledge of milling rock assaying $10 per ton in free gold. They will huild a small hoisting works.

Superintendent W. Graham has resumed operations at the Shady Creek claim, near Nevada City, and the elevator is raising gold-hearing gravel. Water is heing hrought in through the Milton ditch of the California Water & Power Co. Work on the new 7-mile ditch from Columhia Hill, which Drescher & Canfield propose to huild, will he started this month.

Riverside County.

The Oro Opia M. Co. is developing a group of gold mines at Salton. The company is preparing to set up a 75 H. P. gasoline engine and three roller mills and expects to increase the number of men at work.

Shasta County.

The Gladstone mine at French Gulch is in steady operation with sixty men and electric power and a new mill.——The American placer mine is reported to have fifty men operating on Klein's creek.

D. Cone of Red Bluff has 5 miles of land along the hanks of the North Fork of Cottonwood creek, near Redding, under hond to prospect for dredging for gold. The land is 7 miles west of Igo. Keystone drillers for prospecting the ground, and men, teams and supplies are going in.

Sierra County.

(Special Correspondence). — The reported transfer of the Sierra Buttes mine, near Sierra City, is premature. Negotiations are pending.

Sierra City, Feh. 17.

Siskiyou County.

The Mount Vernon group of mines on Cherry Hill divide, near Yreka, has heen sold, and H. D. Lane of Spokane, Wash., is manager.

Arrangements have heen made hy E. T. Wallace with C. Winters to start the dredger at Hawkinsville. They will work the ground of Yreka creek from Shasta river to Yreka. The dredger is to he fitted up for working by electric power.

Trinity County.

The Beale & Temple mine on Quimby creek, a trihutary of the lower Trinity river, near Weaverville, is being developed. The ledge has heen traced on the surface for 1200 feet, says the Trinity Journal. A tunnel has been run on the ledge and a shaft sunk from the tunnel, giving a depth of 125 feet. At the hottom of the shaft the ledge is 25 feet wide. The ore is free milling on the surface, hut carries sulphurets with depth, running in value $12 a ton.

At the Dorleska mine, in Coffee Creek mining section, near Dedrick, the ledge is said to average 15 feet in width. The 10-stamp and Huntington mills are running steadily on ore and forty-two men are at work. The numher will he increased in the spring. M. MacIlwaine is superintendent. There are 4½ feet of snow at the mine.

Tuolumne County.

J. C. Charters has hought the Old Peck quartz mine on north fork of Tuolumne river, near Carters.

Work has heen resumed at the Crystalline mine, near Jamestown.

The Cherokee Gravel & Gold M. Co. of Soulshyville will increase work on its holdings at Cherokee. The main drift is in 500 feet, and when work was stopped last year the face was in pay gravel. Since then the drift has heen retimhered.

Mesgheno, Maddox, Roleri & Gianelli, operating the Duffield mine at Arrastraville, near Soulshyville, under a lease, report opening up high-grade ore and fifty tons are on the dump, which will be run through the Dreisam mill.

G. & W. Connally are taking out gold-hearing quartz from the Side Wiper claim, near Carters. A winze is being sunk and a milling test of the ore will be made. The claim is east of and adjoining the Dead Horse mine.

J. A. Rydberg has sold to the Don Pedro G. M. Co., near Chinese, the right to follow under his lands all veins which have their apexes in the Stokes quartz claim, together with the right to sink shafts, etc. A royalty of 15% will he paid.——Work is under way at the Arhona mine near Tuttletown. It has been closed for three years. —— The Golden West M. & M. Co. has deeded to P. Marsicano for $2500 all its interest in the Golden West mine, on the Comstock ranch, 10 miles east of Sonora.

J. F. and F. H. Baker of Carters have hought the Sunnyside quartz mine, 1¼ mile northwest of the junction of the North Fork and main Tuolumne rivers; also the Hill Top quartz mine, 4½ miles south of Carters, and the Never Sweat quartz mine and mill. —— H. Holmes of San Francisco has bonded the Last Chance, Free Gold, Haley & Wilhur quartz mines, 2 miles east of Jacksonville.

During the shut down at the Black Oak mine, near Soulsbyville, several changes and improvements have heen made. The gallows-frame has been raised and new

ore bins built. Sorting tables have been put in to simplify and facilitate sorting the rock and save handling the ore too often.

COLORADO.

Boulder County.

The Ottumwa M. Co. has been organized to operate the Lord Byron group of mines at Sugar Loaf.

Clear Creek County.

L. S. Kenworthy of St. Louis, Mo., has a bond and lease on the Pacific and other lodes in Jackson and Cascade districts for $50,000, says the Georgetown Gazette. He will start operations this week. The property will be equipped with machinery.

The property of the Two Sisters M. Co. has been sold to J. J. White of Georgetown. It consists of nine patented and four unpatented claims on Silver creek. Operations will be started this month.

C. I. Burt, manager of the Vulcan mine, near Silver Plume, says several additional leases have been granted and all the men are at work opening up their ground. A good tonnage is being taken out. Three raises are being put in within a block of ground 150 feet in length. These raises were started from the 900-foot station of the tunnel, and the vein varies from 2 to 6 feet in width. During the last year the tunnel has been driven several hundred feet. Machine drills were used until a short time ago, when they were discontinued on account of lack of water power.

The J. D. Williamson I. Co. of Idaho Springs has bought the Golden Leaf and Golden Fleece lodes, on Seaton mountain, for $5000. Development work will be started this week.

The Pelican, Dives, Seven-Thirty and Bismarck groups on Brown mountain, near Georgetown, and consisting of 100 patented claims, has been taken over by the Pelican, Dives & Seven-Thirty M. Co., which has been organized by New York and Kentucky men, and the one-half price (said to be $500,000 total) paid down. O. O. McReynolds, of Denver, will be superintendent. All leases now existing will be allowed to operate under previous arrangements. Ore reserves are said to be blocked out in the different veins. The new management has arranged for complete exploration of the group, and all levels are to be driven west. Connection will be made from the Burleigh tunnel level with the bottom of the Seven-Thirty shaft for ventilating, when the level will be driven west.

Custer County.

The Little Jim G. M. Co., working the Bryan mine, has a body of high-grade ore opened in the shaft, but is running a tunnel to connect with the upper workings. It is on Robinson hill, near Silver Cliff.— The Elematah, adjoining the Bryan, will be pumped out and work resumed.——The American Flag is being worked at depth of 180 feet and drifting on three veins is in progress. This claim is owned and operated by Pueblo men. The water that is raised from this mine is used in the Bassick mill, also near Silver Cliff.——The Rappahannock mine, leased to Sandow & Kennedy, has been entered by a 100-foot tunnel under the old workings. Ore is being saved and the mine has again entered the shipping list. The ore runs $70 a ton and carries some copper.

Gilpin County.

F. Augustus of Centerville, Iowa, says operations will be started at the Colorado-Maurer group, near Central City, this week. The Mountain Monarch M. Co. has a lease and bond on the group, which will be operated in connection with the Mountain Monarch group. The Colorado-Maurer has been idle for several years. It is intended to carry on developments through tunnel workings.——Work is under way on the Fort Logan tunnel property, west of Rollinsville, by the lessees, Fairchild & Galligan of Denver.

The Onoko G. M. Co., operating in Leavenworth gulch, near Central City, has resumed sinking operations. The shaft is down 220 feet and the company will sink at least 100 feet deeper. Developments are being carried on in the 120 and 220-foot west levels. In the 220-foot level there are six inches of solid copper ore, says Manager Shull. He will also raise from this level to make connections with the winze being sunk from the 120-foot level, which shows ore.

The Robert Emmett G. M. Co. has sold to the Stephens I. & T. Co. the Robert Emmett and Virginia Extension lode claims, on Maryland mountain in Chase gulch in Gregory district, near Central City, for $50,000. The property has been idle for several months. It is equipped with machinery, top buildings and has a shaft down 400 feet.

Uranium ore is reported being taken out of the Wood mine, in Leavenworth gulch south of Central City. The uranium shoot varies from 3 to 5 inches in width, alongside of which are copper and iron deposits carrying gold values. The ore is being taken from the bottom of the shaft at depth of 250 feet. The mine is owned by Eastern men and is under bond to local parties.

Gunnison County.

The north and south Hall's gulch tunnels, near Pitkin, are being driven with air drills and each is in 500 feet. The north tunnel is being run to cut the mineral-bearing contacts of the Mineral Farm basin, and the south tunnel to open up veins of the Silent Friend group at depth.

Hinsdale County.

T. Watson and W. Lynd are working the Cora and Sulphurets group under lease. The group is 1½ mile southeast of Lake City.——Gannon & Kranichfeld have a body of ore opened in the Pride of America.——It is said the Colorado & Connecticut G. M. Co., owners of the Dolly Varden group, will develop the two veins of the property during the coming spring.

Jefferson County.

The Morrison mine on Bear creek is being worked again. The ores carry copper values. The shaft is down 124 feet and it is intended to sink to depth of 200 feet and extend the levels, says Superintendent M. W. Dillon. A plant of machinery has been placed on the mine and fourteen men are at work. The mine is on Bear creek, 7 miles above Morrison.

Lake County.

The Yak tunnel at Leadville is driving on the Silver Cord property, a spur of the tunnel cutting into the claim. At the 100-foot mark levels have been started and one runs to the end of the Moyer, a distance of 540 feet, all in ore. At the bottom of the winze a level has been run south 380 feet and has tapped the Eagle raise and gone under the main tunnel. The ore body being worked is said to be an extension of the Moyer ore shoot.—— The Cord ore shoot in the tunnel has been opened by 1500 feet of drifts, 300 feet of raises and a winze 160 feet in depth. From other parts of the property a good grade of sulphides and iron is being shipped, the daily tonnage amounting to 150 tons.

C. H. Stead et al., operating the Dunkin mine, under lease from the Fryer Hill M. Co. at Leadville, are shipping two cars of high-grade iron a day and are driving development work.

The Dennis claim in St. Kevin, near Leadville, has made a find off from the 150-foot shaft. A drift was run at the 100-foot level and when in 43 feet it struck silver ore which averages 200 ounces silver per ton. J. Partridge, J. Parker et al. of Leadville are interested.

La Plata County.

(Special Correspondence). — A gold strike was made early in January on the Bulldozer claim, Lewis gulch. Some rich ore had been taken from this mine years ago, but the vein had been lost and the property lay idle for several years. Recently Durango leasers opened 18 inches of ore which assayed twelve ounces gold per ton, with some silver. Further work developed a vein 3 feet in width, which averages above $100 per ton, as shown by a shipment to the Durango smelter.

In the Little Rock claim, Oro Fino district, at a depth of 20 feet samples gave gold values of 8.41 ounces. It is claimed that the vein is 20 feet wide and all of it will pay to mill.

The mill of the Neglected mine is treating seventy tons of ore per day with satisfactory results.

The Chief M. Co. is pushing the work of building. The working force will be increased.

At the May Day a large crew has been added, which is facing up for the proposed tunnel and grading for the compressor plant on the flat near the river.

Mancos, Feb. 1.

Ouray County.

The mill of the Barstow M. & M. Co. in Commodoro gulch, 1 mile west of the Guston mine, near Ironton, began crushing ore this week. Electric power to run the five electric motors is brought over the range from the Ames power plant on the Telluride side. The Bobtail mine is the main vein worked by the Barstow Co. A tunnel, 2800 feet, is driven, exposing the vein for a distance of 2000 feet. The lode, which has northwest strike and dips southwest at 45°, is 40 feet in width. The concentrates for the present will be shipped via Ouray, but in the spring it is expected the Silverton & Red Mountain Railroad will be extended to that point, which will take the ore via Silverton to the smelter at Durango. It is the intention of the company to double the capacity of the mill in the summer, which, when completed, will give it eighty stamps dropping.

San Juan County.

The Alta claim, 1 mile from Chattanooga, near the Ophir road, near Silverton, is being worked this winter under bond and lease by F. Schurman et al. The tunnel run in on the vein shows a lead, with a pay streak 6 to 8 inches wide, with values in gold, silver, lead and copper. A new crosscut tunnel has been started 160 feet lower down than the present workings.

The Sunshine mine, above Eureka, at mouth of Picayune gulch, owned by the Wigwam M. Co., is being worked this winter by contractors driving a tunnel. The company has a group of eight claims. Last season a power plant was built which is run by water power. The fall of the water is 500 feet. It is proposed to put up a concentrating mill near the power plant.

San Miguel County

Work at the Tomboy mine and mill, near Telluride, is being steadily increased. Fifty stamps are dropping. This number will be increased as conditions warrant. At present the operations are being concentrated in the Argentine workings, where five levels are being worked in addition to the stopes. There are 250 men employed in the mine.

In March operations for the year will be begun at the Keystone placer, on the San Miguel river, 5 miles below Telluride. The two dams that were washed away last August by freshets caused by a waterspout at the source of the San Miguel river have been rebuilt. Two reservoirs that were destroyed at the same time have been replaced and enlarged. Over 1000 feet of additional sluice boxes have been built and new iron riffles have been put in for a total distance of 300 feet below the gravel pit, says the San Miguel Examiner. A 12x14-foot flume extending 600 feet has been built. E. L. Davis, a director in the company, says twenty-five men will be kept at the Keystone during the open season.

Summit County.

In the Wellington mine, near Breckenridge, operated by R. W. Foote et al., shipments are continuous from the lead-zinc vein, and the iron vein has been opened by crosscuts.

Teller County.

The Gold Nugget M. & L. Co. has been incorporated at Cripple Creek by L. E. Kimball, A. T. Pierce, G. L. Weaver, T. Ramsay and F. Richter.——The Gold Ore Leasing Co. has been incorporated in Denver by N. E. Kimball, G. L. Weaver, A. T. Pierce, E. P. Brown and M. T. Gunderson.

The Free Coinage M. Co., owning acreage on Bull hill, Cripple Creek, has given option of a five-year lease on the company's entire holdings. The lessees are to sink a shaft from surface, as a three-compartment working shaft, and to be sunk 200 feet per year during the period of the lease. The royalties are 25%. During the past few years the property has been worked exclusively by lessees. There are five sets of lesseeS operating at present, but these leases expire this month. Controlling interest in the Free Coinage is held by the S. Strong estate.

Engineer A. C. Jaquith of the El Paso drainage tunnel reports that last week the measurement showed 6500 gallons per minute flowing out. The men who are extending the east lateral are breaking down 30 inches of rock per day. They have not yet cut through the dike. As it is, the Elkton and Mary McKinney mines are being unwatered rapidly, and it is expected they will be able to get into their lower workings next week.

Governor Peahody last week terminated the exercise of martial law in Cripple Creek district, and the troops have delivered all military prisoners to the civil authorities.

The report of the Anaconda M. Co. of Cripple Creek for year 1903 shows there are thirty-five sets of lessees working the 100 acres of patented Gold Hill property, including the ore-house waste lessee. The production of all the lessees aggregated 2895 tons; gross value, $69,210.95; net mill returns, $45,528.95. The company's royalties amounted to $10,881.59, which, with rents, transfer and air accommodations, charged to lessees, brought total receipts for year to $16,671.66. The expenditures, including $4000 assessment to the drainage tunnel, $1200 manager's salary and $2747.65 taxes, aggregated $10,-933.33. In addition, mining expenses, of which lahor, fuel and water and bookkeeper's salary were chief, totalled $8169.42. F. J. Campbell, secretary and manager, says the drainage tunnel is lowering the water level of the mine at rate of 6 inches a day.

IDAHO.

Blaine County.

Superintendent Smith of the Carbonate Hill M. Co., operating mines on Cherry creek near Galena, near Ketchum, is preparing to put in a steam plant for his mines, as the water power cannot be depended on the year around. Taking water from near the head of the creek, it froze in the ditch last month. This compelled him to shut down the air compressor and resort to hand drilling.

Boise County.

The Mary Jane shaft, on Willow creek, near Idaho City, is down 192 feet. It has cut into the ledge 10 feet, showing ore which is expected to mill $3 per ton. The ledge has a 6-inch shoot of high-grade rock also, says G. A. Williams, superintendent.

Idaho County.

A strike has been made on the Silent Friend group of claims at the head of Big crook, near Roosevelt, in Thunder Mountain district. In running one tunnel a streak of sylvanite ore was cut at distance of 120 feet and about the same depth. The company is running two tunnels. The other tunnel is in 75 feet. A stringer of ore 12 inches thick has been struck, assaying $40. The company is owned by F. L. Thompson, G. B. Rogers, J. Howson and E. A. Johnson of Boise City. M. Jacobs is manager.

The Dewey mill at Roosevelt continues in steady operation, with ten stamps dropping, and twenty-five tons of ore per day are being run through. The company is employing thirty-five men.——The Sunnyside M. Co. is working thirty men. —— The East Dewey, owned by the Van Riper Co. of New York, is working eight men, and the H. Y. group, owned by the Perkins Co., is working ten men. — On the Mysterious Slide mine, owned by B. Caswell and M. Cowan, men have been kept constantly at work, and a 300-foot tunnel has been run into the claim, passing through 100 feet of sulphide ore.

Shoshone County.

The Bunker Hill & Sullivan M. Co. at Wardner is preparing an underground station ½ mile in the Reid tunnel, to move the blacksmith shop from the outside of the tunnel to a more convenient place on the inside and save hauling the steel to be sharpened that distance. The head blacksmith has six men to sharpen the steel, which will all be done on the inside, says the Review.

MICHIGAN.

The producing copper mines of Lake Superior are stamping over 1000 tons of rock per hour. The Calumet & Hecla at Calumet leads with tonnage of 5700 daily, the Osceola at Opechee has 3600 tons, the Quincy at Hancock 3500 tons, and the Tamarack near Calumet 2500 tons. The Winona at Winona has daily output of 200 tons; the Baltic, Champion, Trimountain, Wolverine, Mohawk, Franklin and Atlantic are each stamping between 1000 and 2000 tons daily. To furnish the power required to mine and crush this rock requires 100 tons of coal per hour, and 15,000 men are on the payrolls, besides giving indirect employment to thousands of other workmen in forests, on the railroads and sailing on the Great Lakes.

Houghton County.

Deed conveying the Arcadian mill to the Centennial M. Co., near Calumet, has been filed. It is said the price was $325,-000. The mill is said to have cost the Arcadian $480,000. The millsite includes 1¼ mile of shore front and contains 400 acres. President H. F. Fay reports to the company that on reaching the twentieth level the quality of the rock made it seem advisable to sink further, and the shaft has been sunk down to the twenty-fifth level and drifts started north and south of the shaft. These drifts—now 1250 feet long—which can be extended half a mile before reaching the boundaries, have opened ground of value. Since the twenty-fifth level was reached one drill has been used for sinking and the shaft is well below the twenty-seventh level, and several hundred feet in the twenty-sixth and twenty-seventh levels have been drifted, which show similar run of ground as exposed in the twenty-fifth level. The mine will be developed to furnish 1000 tons of rock per day to the mill. No. 2 shaft will be sunk from the surface to the ledge and from the twelfth level to the depth of No. 1 shaft. The rock house at No. 1 shaft, capable of holding 3000 tons of rock, will he finished, and shaft house on No. 2 will he built. Trostle from No. 1 to No. 2 will be erected and the shops will he removed to the Kearsarge location.

The Isle Royale management at Houghton has let contract for construction of stone and cement dam in the fourteenth level, connecting Nos. 1 and 2 shafts, as it is intended to abandon the burned out No. 1 shaft and allow it to fill with water, says the News.

Houghton reports say the management of the Quincy mine and the strikers are further apart than ever, and the young men among the strikers are leaving for other mines. The company has withdrawn the offer of $57 as a compromise and the miners have voted to stand by the trammers. At the smelter the management is putting in improved methods of casting copper, using the trolley system for handling ladles. Two furnaces are running on mineral from the Mass, Michigan, Adventure and Winona mines.

All the machinery for the hoist at No.

5 Tamarack shaft, near Calumet, is on the ground and being set up. It is expected the hoist will be ready for operation by March 1.

The Calumet & Hecla, near Calumet, has opened into the Kearsarge lode in No. 19 shaft, nearest the Centennial, at depth of 95 feet, the vein showing shot copper. This shaft is a vertical one and on hanging side of the lode. The striking of this lode by the Calumet & Hecla gives the mine three working lodes.

The January product of the Quincy mine, at Hancock, amounted to 601 tons 1635 pounds of copper; and the Franklin produced 359½ tons.

The Quincy mine strike at Hancock was declared off last week, the men voting to accept the company's compromise offer of $58.50 per month. Fifteen hundred men were idle sixteen days, but there was no violence.

The aggregate rock shipments being handled by the Copper Range railroad of the Copper Range Con. C. Co. amount to 5300 tons daily. The first increase over these figures will occur this month, when the four Baltic stamps are to be run to full capacity.

The Wolverine mine, near Calumet, during January yielded 505½ tons of copper.

Sinking in No. 19 shaft of the Calumet & Hecla, near Calumet, which struck the Kearsarge amygdaloid lode recently, has cut the hanging wall of the lode. The Kearsarge is mineralized for its entire width. It is expected work will be started on a permanent shaft, which will go down on the dip of the lode. In No. 20, the second Kearsarge exploratory shaft, sinking is under way at depth of 80 feet. A 3-inch air pipe has been laid from No. 17 engine house to No. 20 shaft to furnish air for the drills. A headsheave and larger hoisting engine are being set up. The Calumet & Hecla has resumed hoisting with the Hancock and Pewabic hoist, having replaced the cracked shaft with a new one. The hoist has been idle since August 24th last.

A rock crusher, said to be the largest in the copper country, weighing 24½ tons, has been completed for the Michigan Smelter Co., near Houghton. It will be used for crushing slag and have capacity of 1000 tons per day.

The January production of the Baltic mine of the Copper Range Con. C. Co., near Painesdale, amounted to 698 tons of copper, as compared with 701 tons in December. The Trimountain production was 595 tons, compared with 547 tons in December.——The Champion, also near Painesdale, produced 731 tons of copper in January.

Keweenaw County.

During January the Phœnix mine, at Phœnix, produced seventy-one tons of copper, including eighty-two barrels of mineral, from one head stamping. The rock averaged 1⅞%.

The Mohawk No. 4 steel shaft house near Allouez has been completed.

MISSOURI.

The year 1903 brought to the Missouri-Kansas mining district the largest returns for ore sales of any year except the "boom" year 1899, says the Joplin News-Herald. Last year's total zinc and lead sales in the district aggregated $9,452,840, or $21,690 more than the sales of 1902. The output, however, was less than that of 1902 by 27,813 tons of zinc ore and 3177 tons of lead ore. The improved methods adopted by many of the mines have added largely to the profits. Only a few mills were built in the district during the year, but considerable prospecting was done, which will result in building of mills as soon as the natural course of development will warrant. "The district is profiting by the lesson learned in the boom days of 1899, where costly concentrating mills were built over holes in the ground that could claim no pretensions to being mines." One difficulty the district had to contend with last year was the scarcity of coal, the railroads at times being unable to supply the district's demands for coal. ——The present year promises a larger output of both zinc and lead ore. Discoveries have been made by drill prospecting, which are expected to develop into producing mines in time to add to the output of 1904.

The total output for 1903 was 234,733 tons of zinc ore and 28,438 tons of lead ore, of a total value of $9,452,840. The average price paid for 60% zinc ore for the year 1903 was $54.55 per ton.

Jasper County.

At Webb City the Southwestern P. & Dev. Co. has been incorporated to prospect leases by drill and sublease to miners. The officers are: G. W. Moore, O. E. Duenweg, E. C. Walden, C. N. Chrisman and G. W. Strain, the last named being manager. The first year's work will be done in the proven territory of the Webb City–Carterville district. They propose putting at least three drills to work. They will keep an accurate record of each drill hole.

The Independent M. Co. has completed a mill on its lease on the Guinn land, at Webb City. Automatic feeding devices are a feature of the construction, and Superintendent Conkey expects to handle 250 tons per shift with only three men. ——The Congress M. Co. (one of the Morton properties) on the Guinn land is overhauling its mill, raising the tailing elevator, and getting ready to start mining. This prospect was formerly the Narragansett.——The Yale mill of the Old Colony Z. & L. Co. on the Missouri Zinc Fields land, is being arranged so it can run custom dirt as well as from their own lots. Additional milling capacity is needed on this ground to accommodate the large number of small lessees who have as yet no mills of their own.

The Cunningham fee of 129 acres, west of Joplin, is becoming a producer, says the News-Herald. J. Aldrich has a lease of twenty acres of the Cunningham land, and on this lease there are ten drill holes, nine of which show ore. The shaft is 129 feet deep. Drill holes on the west and south of this twenty-acre tract have struck the same ore formation. On the northeast adjoining is the May Bell lease, on which they have struck a body of ore at the 140-foot level, and are in 8 feet of ore. The Bunker Hill adjoins the twenty-acre tract, the Quaker on the west, the Jack Rose on the north. Aldrich expects to strike ore at 162 feet.

The Ground Floor M. Co., composed of Cleveland men, who have a lease of ten acres of the Randolph M. Co.'s lease of the Guinn land, north of Webb City, and south of the Golden Rod, have started operations. They are sinking a shaft 6x8 feet in the clear, using steam drills, says Manager Bendelari.

Joplin reports say the highest price paid for zinc ore during the past week was $38 per ton, and for lead $57.50 per ton. The shipments were larger than the preceding week by 1,175,280 pounds of zinc, but was 486,810 pounds of lead less.

The Jewel C. mill, near Carterville, operated by Carmean & Canada, has begun regular operations. The mill and hoisters are operated by electric motor, power being furnished by the Missouri Zinc Fields Co. They are hoisting dirt from the level which has been under water for the past year.

J. O. & D. Flynn, F. Ozburn, G. A. Case, M. S. Montague, C. T. Hanshaw, R. D. & W. C. Martin, J. W. Duncan and S. Etter have organized the Velvet M. Co. of Missouri in Joplin.

Lichliter & Varner have their mill at Alba in operation.——S. D. Mitchell has added forty-two acres to his holdings by buying the S. B. Holden tract, northeast of Zincite, for $10,500.——Stevenson & Bourne, W. Roberron et al. have struck a favorable prospect on the Wiley Webb forty at Duenweg. In sinking the shaft they have been getting some lead and jack from 45 feet down to 80 feet, and at 80 feet they broke into a body of jack.

Lawrence County.

J. B. Davis has his concentrating plant on the Shipman land, near Stott City, complete. He has two drills running on adjoining land.

MONTANA.

Beaverhead County.

The Hecla Con. M. Co., with headquarters at Melrose, Silverbow county, has put in a heavier pump in the Cleve mine at Hecla, and is working fifty men. As soon as the pump clears the mine of water more men will be put on. Ore is being shipped.——The Montana G. Dredging Co. has decided not to start their boat the coming season. This company owns holdings on Grasshopper creek from the Bon Accord mine to mouth of creek at Beaverhead river, about 9 miles.

C. M. Stolle and G. Eighorn are working the Trapper mine, one of the Hecla group at Hecla. The ore value is principally silver, but the quartz carries some copper and lead.

Deer Lodge County.

Development work is being increased on the Southern Cross mine, near Anaconda. It is intended to sink the shaft 200 feet. The company is shipping ore. The presence of iron in the ore lessens cost of smelting, and, in some shipments, pays the whole cost, says the Inter-Mountain.

Fergus County.

Smelting ore is being shipped from the Black Horse group of claims in the South Moccasin mountains, near Lewistown, by R. E. Hamilton, owner. The ores of the Black Horse have their principal values in lead, with some silver, gold and copper. Hamilton has five claims along the lead and expects to ship three cars of ore weekly. The width of the vein is 3 feet.

Jefferson County.

The New York & Montana C. M. Co. has been incorporated under Dolaware laws to work the McCabe group of mines in the copper district of Corbin, by M. Hyman, A. L. Curtis, A. B. Camphell and D. Sage of New York; G. Sumner and D. W. Morrow of Englewood, N. J., and J. Virdin of Dover. Three shafts are being sunk on the group, one of which has reached depth of 134 feet, another 60 feet and the third 50 feet. Development work has been encouraging.

The Eva May mill, 6 miles from Basin in the Cataract copper mining district, will be enlarged. It is owned by the Montana Mineral Land Dev. Co. The mine has bodies of copper ore blocked out and has been opened up by a vertical shaft to depth of 650 feet and levels run at the fourth, fifth and sixth to distances of respectively 1200, 1500 and 1400 feet. From the 600-foot level a winze has been sunk to depth of 80 feet, opening up a body of chalcopyrites. This mine is equipped with a hoisting plant. The mill capacity will be doubled to 150 tons a day. New tables will be added. At the mine the plans include sinking the main shaft to additional depth of 200 feet.

Powell County.

A boiler and machinery are on the ground for the Montana United M. Co., near Emery.

Silver Bow County.

The indications are that this year will be the most prosperous in the history of copper mining in Butte, says the News. The capacity of the Butte, Anacouda & Pacific and the Great Northern railroad companies is being taxed to handle the ore sent to Anaconda and Great Falls. The Washoe copper smelters at Anaconda are working full blast and concentrate, melt and turn into ingots 6000 tons of ore daily.

NEVADA.

Humboldt County.

At Rebel Creek Superintendent J. J. O'Connell reports they are making progress in driving the 500-foot tunnel on the Sunburst mine. Bad air causes some trouble, but they are putting in pipe for ventilation. They are driving the tunnel on the vein. The ledge is 150 feet wide. After they run 400 feet they will drive crosscuts both east and west.

Lander County.

W. Licking has bought half interest in a group of copper claims 6 miles west of Battle Mountain. Licking has men at work taking out ore for shipment.

Lincoln County.

West of the mill the Quartette M. Co. at Searchlight will build an electric plant. The site has been graded. Two gasoline engines will drive the generators. The power will be used to operate the pumps and for lighting purposes. Later an electric line will be installed to tram the ore from the Copper King mine to the mill. To prevent seepage of water from tailings ponds back into the mine, it is proposed to use a series of settling tanks.

T. O'Connor has bought the Yellowstone mine, near Searchlight. —— The Empire mine has men at work and has struck water in the Mountain Jewell shaft at depth of 140 feet, says Superintendent Ross.

Nye County.

The Dolores Turquoise M. Co. has begun operations on its property at Ray, near Tonopah, under management of J. C. Conklin.

Washoe County.

On the 260-foot level in the Wedekind mines, near Reno, it is reported, they have again cut the shoot of high-grade ore. J. Sparks, owner, says he makes no distinction in the class of ore, however, and the rich with the lean finds its way into the mill, which will again be put in operation this month.

A slime pond is being made at the Olinghouse mill, at Olinghouse, to impound the tailings which it is expected to cyanide.

The Slip mine in Olingbouse canyon, near Wadsworth, has been sold to the Springfield–Nevada M. Co. for $10,000 cash.

NEW MEXICO.

Colfax County.

Over 300 men are at work in the coal mines being opened up at Willow Arroyo, says the New Mexican. The mines at Blossburg may also be reopened in the spring.

Grant County.

The North American, Aberdeen and American Con. companies, operating in Shakespeare district, south of Lordsburg, are all preparing to resume operations, says the New Mexican. The Dakotah Pearl is a copper proposition, owned and operated by the Michigan–New Mexico C. Co. The mine is down 300 feet and showing ore running 4% in copper and carrying gold and silver values. The management will put in heavier machinery.

Wilson & Co. have two leases, one on the Romero and one on the Chino ground at Santa Rita, says the Silver City Independent. On their lease on the Romero are two shafts, one 70 and one 90 feet in depth, from which drifting and cross cutting has been done, opening up several veins. The ores are sulphides, carbonates and glance. The Tin Can shaft on the Chino lease has depth of 110 feet and is in ore carrying a 12-inch shoot of black sulphides averaging 17% copper.——Riney & Co. are leasing on the Romero and making monthly shipments of 150 tons, averaging 20%. —— H. W. Dawson is leasing on the Chino and employs fifteen men, who are working on contract; depth of workings, 150 feet; production, forty tons of 20% copper ore per month.—— Dawson & Co.'s lease on the Aztec has opened up a body of ore showing red copper oxide and native copper. Twelve men are working and thirty tons of ore are shipped each month.——Selleck & Co. are operating the Crawford & Fritter lease, shipping 100 tons of ore monthly averaging 15% copper.——Ernest & Islas are on the old workings of the Romero. The depth of the shaft is 100 feet. The ore body has been crosscut 40 feet and stoped up 40 feet, showing red oxide and native copper, averaging 25%. Production of 100 tons per month is being made. These lessees are sinking another shaft 160 feet north of the present one.——Crawford & Co. have a lease on the Chino and employ twenty-five men; output, 100 tons per month. This lease is equipped with steam hoist, three whims and a windlass. Most of the ore mined comes from the 125-foot level. The ore is red oxide, copper glance and carbonates.——The McGregor Co. is operating through the old Romero shaft, which is equipped with steam hoist. The shaft has depth of 400 feet, but the ore at present mined comes from the 150, 200 and 300-foot levels; production, 100 tons per month, averaging 20% copper. The above shipments in most cases represent sorted or concentrated ore.

Rebuilding the mill of the Aberdeen M. Co., near Lordsburg, has been completed and concentration of ore resumed. Regular shipments of concentrates will be made to the smelter.

Luna County.

The Sierra Florida M. Co. will put up a smelter at or near Deming to treat its ores.

San Miguel County.

A tunnel has been driven on the Apex mine, 30 miles northwest of Las Vegas, near head of north fork of Gallinas river. The tunnel is in 60 feet on the vein. Ore is showing at the face, 4 feet in thickness carrying pyrite with silver and gold values. A stationary engine and diamond drill are being set up at the coal mine being opened near Trout Springs, near Las Vegas. J. Leonard, superintendent, says he is testing a 5-foot vein of coal.

Sierra County.

The hoisting machinery at the Empire mine, near Hillsboro, is in position and two shifts are at work on the mine.—— The Kanawha G. M. & M. Co. has an option on the Good Hope Bonanza mines, near Hillsboro. —— El Oro mines at Andrews will resume operations this month.

Taos County.

The Jayhawk G. M. Co., at Red River—L. Rogers, of Waco, Texas, president—will resume work on its mine and mill in the spring. Ore bins are being built, and machinery set up at the mill to concentrate the ore. Work on the tunnel and shaft will be increased. R. P. and J. Kelley are developing the Silver Bow mine, on Placer creek. The ore assays ninety ounces of silver with gold values. G. D. Jordan is developing a wolframite property also near Red River.

OREGON.

Baker County.

A. B. Ernst, manager of the Virginia mine, near Sumpter, says the rotary mill now on the property will be replaced by ten stamps. Lumber to make the necessary changes in the buildings is on the ground, and it is expected to be again in operation in March.

E. S. and C. E. Platts of Baker City, owners of the Platts group in Rock Creek district, are preparing with A. G. Wintz of Ellensburg, Wash., to develop other Rock creek properties in which they are also interested.

The controversy over the ownership of certain mining grounds claimed by the Baby McKee M. Co. and the Eagle M. Co. has been compromised by a division of the disputed territory. The former owns the Baby McKee and the Last Chance groups and the latter the Imperial group, and between are the Annex lode of the Imperial and the Infidel lode of the Baby McKee group. By the settlement the development of these will go ahead.

Curry County.

Portland reports say a strike has been made in the mountains of the Sixes region, on Sixes river, Curry county. A gravel bed or channel has been uncovered by the Sixes M. Co. that is giving returns of $1 a pan. The bank has a depth of 20 feet to bedrock. In the early days the

Sixes river channels were worked to some extent with shovel, recker and sluice, but the banks were too deep and closely cemented to be worked by hand. During the past season the Sixes M. Co. has put in hydraulic equipment.

Jackson County.

Mining Superintendent Orme, for the Condor Water & Power Co., will next month begin work of installing a 20-stamp mill at the Braden mine, near Ashland, to be operated by electric power from the Gold Ray station. The power line will be 4 miles in length. Electric power will be used to operate the drills, hoisting and other machinery about the mine. Bodies of ore are blocked out.——Work is going on at Whitman & Heard's Ore Grande M. Co.'s placers on Carbury fork of the Applegate. The plant is being increased to three giants. The Misseuri M. Co., in which Smith & Warner are interested, is also operating a placer on Carbury with a No. 2 giant.

The dredger of Champlin & Co., on Foots creek, near Gold Hill, has been launched and is receiving its machinery. A boiler, weighing nine tons and of 120 H. P., is being set up. All of the other machinery for the dredger is on the ground. Champlin & Co. have two dredgers at work near Bannock, Mont.——The work of overhauling and placing new machinery has been completed at the Sturgis hydraulic mines on Forest creek. Among the improvements are a derrick for handling the boulders, and a complete electric lighting plant.

Josephine County.

Spokane, Wash., men have bought the Lucky Queen mine, Jump-Off-Joe district, near Grants Pass. C. D. Grane is superintendent and has restarted development. For several years the Lucky Queen, which at one time was equipped with a mill and plant, has been idle. The workings are being cleared and retimbered and new tracks will be laid, etc.

Development work is progressing on the copper mines of southern Josephine county, aside from that under direction of the Walde S. & M. Co. at Waldo. Among these is the Queen Bronze on the Illinois river. It is owned by Colorado men. A shaft was sunk 110 feet and a drift is being run on the ledge from this level. C. J. Murphy is superintendent. ——Farther south, on Shelley creek, is the Monumental mine, being developed under bond by T. W. Draper and California men. Fifteen men are at work. Values are carried in copper, gold and silver. The ore is said to be a concentrating and cyaniding proposition. ——Little work is being done at the mines of the Waldo S. & M. Co. They are well developed and ready to begin output as soon as the smelter is built.

A hydraulic mine is being developed in Humbug district, on Applegate river, south of Grant's Pass, by White, Christian & Benson. A reservoir has been built and a No. 2 giant set. It will be operated under 150-foot head. Piping began last week.

The Williamsburg M. Co., of Portland, has resumed development work at its Williamshurg mines on Williams creek, says the Ashland Tidings. The mines are equipped with an 8-stamp mill.

The tubular elevator for the Deep Gravel hydraulic mines at Waldo has been set and is at work, says Manager W. J. Wimer.

SOUTH DAKOTA.

Lawrence County.

The Golden Empire M. Co. has opened up a body of quartz ore in a shaft started on the Eureka claim, in Bear gulch, near Welcome City, west of Spearfish. The ledge is 300 feet in width and pans $3 per ton in free gold. The ore is said to also carry tin. It is intention of the Golden Empire Co. to put the 20-stamp mill in operation on ore from this ledge this month.

The Big Four M. Co. has cleared away the ruins from the fire at the shaft along upper Deadwood gulch, near Deadwood, preparatory to rebuilding the shaft house. A new hoist, boilers, air compressor, pump and other machinery will be put in. It is expected to be ready to resume by May 1st, when work of sinking the shaft, now down 170 feet, will be continued to the 500-foot level.

The Buxton mine, at Terry, in Bald mountain district, consists of one claim and a fraction, ten acres being the size of a claim in the days of its location. J. Lundberg, with Dorr and Wilson, have built a cyanide mill on the property and the mine is again being worked.

UTAH.

Beaver County.

The Monarch M. & S. Co. has been incorporated under Maine laws. A. B. Lewis of Salt Lake City is manager. The Monarch combination will include the Comet group, adjoining the Cactus mine, of the Newhouse M. & S. Co. at Frisco: the Imperial mines in the San Francisco range of mountains; the properties of the Royal G. & C. Co. in Beaver and Iron counties; the Manhattan and Pioche Con. mines at Pioche, Nev., and the Last Chance .. ine at Bingham.

Juab County.

S. McIntyre of Salt Lake City, president of the Mammoth M. Co. at Eureka, says his company prepeses building a smelter. The old mill belonging to the company may be utilized. The Mammoth is well supplied with water and sufficient pumping capacity.

Salt Lake County.

The Eureka-Ophir is the only property being worked at Dry Canyon, near Bingham. The Pittsburg-Utah has suspended operations.

Steel for the addition to the Highland Boy smelter at Bingham is arriving. The order calls for delivery of over 500 tons of structural material. The management expects to have the plant ready to go into operation June 1st.

Summit County.

The Pinyon Ridge M. Co. has been incorporated, under Maine laws, by J. M. and F. J. Goodwin of Biddeford, Me.; J. A. Snow and J. Berry of same State, J. McGregor, F. and S. C. McKeen, B. V. Marshall, H. and L. McDenald. J. McGregor of Salt Lake City is president. The holdings of the company are at Park City and consist of a portion of the Pinyon and Pinyon Extension and portions of the Walker and Buckley, on Crescent hill, the Nettie and an interest in the Roaring Lion. These claims are surrounded by the claims of the Kearns-Keith M. Co. on three sides and adjoin the property of the Silver King on the other. In addition to these, the company owns holdings which adjoin the property of the Silver King M. Co. on the north, west and southwest—in all thirty-one patented claims, besides others unpatented, the whole covering 400 acres. The company also owns easements in and on the Kentucky No. 4 and Kentucky No. 5 mining claims, also rights of way through the mining claims of the Silver King M. Co. for tunnels.

The Daly-West mine at Park City is shipping from 1300 to 2000 tons a week of ore and concentrates. Shipments from the Silver King run from 800 to 1200 tons, and the Keith-Hearns mill is turning out weekly seventy tons of concentrates.

The machinery at the Ontario concentrator at Park City was put in operation last week, says Superintendent Moffatt. The number of men at the mine will be increased to fifty.

Washington County.

J. S. Ferris says the coal measures recently found in Washington county are 5 miles south of the line between Iron and Washington counties, on Peter Leap creek, and 7 miles from the Harmony coal mine, near Cedar City, Iron county. The vein was found by H. S. Marshall of Tropic near the site of the church diggings which were worked in 1874. The footwall is sandstone, with limestone and then conglomerate on the hanging. H. S. Marshall of Tropic, W. Harris of Leeds, A. F. Gregerson and J. S. Ferris of Bellevue and J. V. Ferris of Colorado City, Colo., have each located a quarter-section of the land and they have formed a company to develop the ground. The vein is 4 feet wide.

WASHINGTON.

The report of State Coal Inspector C. F. Owen shews the past year has been a favorable one to the coal mining industry of the State, the total output having increased 18.57% over output for 1902, while fatalities in the mines show a decrease of 26.60%. During the year 1903 there was a total of 948,909 tons of coal exported to points outside the State. Improvements have been made in all the principal mines of the Northwest Improvement Co., the Pacific Improvement Co., the Issaquah Co., Carbon Hill Co. and several others. The resumption of tariff on foreign coals will increase Washington's export shipments. The producers were as follows:

	Short Tons Mined.
N. W. I. Co., Roslyn (Kittitas county)	1,032,530
N. W. I. Co., Cle Elum (Kittitas)	331,400
Summit C. M. Co., Cle Elum (Kittitas)	2,000
D. A. Brown Co., Roslyn (Kittitas)	3,000
Roslyn Coal Co., Roslyn (Kittitas)	7,087
Pacific Coast Co., Franklin No. 1 (King)	90,159
Pacific Coast Co., Newcastle (King)	145,374
Pacific Coast Co., Lawson mine (King)	86,987
Pacific Coast Co., Franklin No. 7 (King)	82,480
Pacific Coast Co., Franklin Gem mine (King)	65,646
Black Diamond Coal Co., Black Diamond (King)	278,922
Seattle Electric Co., Renton (King)	134,743
Issaquah Coal Co., Issaquah (King)	105,643
Denny Clay Co., Kummer (King)	10,705
Occidental, Palmer (King)	16,024
Fred Nolte Co., Cumberland (King)	6,700
Snoqualmie C. & C. Co., Snoqualmie (King)	5,000
N. W. I. Co., Ravensdale (King)	187,900
Carbon Coal Co., Cumberland (King)	235
Carbon Hill Coal Co., Carbonado (Pierce)	280,123
South Prairie Coal Co., Burnett (Pierce)	69,912
Wilkeson Coal & Coke Co., Wilkeson (Pierce)	55,399
N. W. I. Co., Melmont (Pierce)	83,100
W. A. Co., Fairfax (Pierce	33,600
Gale Creek Coal Co., Wilkeson (Pierce)	37,182
Black Carbon, Pittsburg (Pierce)	4,000
Montezuma, Fairfax (Pierce)	11,970
Skagit Coal & Coke Co., Cokedale (Skagit)	19,256
Blue Canyon Coal Co., Blue Canyon (Whatcom)	600
Marion Howell, Centralia (Lewis)	1,300
Crescent Coal Co., Chehalis (Lewis)	500
Great Western Coal M. Co., Tenino (Thurston)	1,000
Total	3,190,477

The output by counties was:

	Tons.
Kittitas	1,376,017
King	1,216,518
Pierce	575,286
Skagit	19,256
Whatcom	600
Lewis	1,800
Thurston	1,000

The total value of the coal mined in 1903 was $6,380,954, based on $2 per ton at the mine; and the average wage charge per ton of coal mined is $1.25. In addition there were 47,916 tons of coke manufactured at a value of $239,580 at the ovens. The coal mining industry gave employment during the year to 4876 men, whose total earnings were $3,982,184, based on an average daily wage of $2.67. There were twenty-five fatal and eighty-three non-fatal accidents in the mines in 1903.

Cowlitz County.

J. P. McInerney, of The Dalles, Or., secretary of the Coal Creek Coal Co., says the company is taking out coal from its mines in Cowlitz county and will ship it to the Columbia river. The coal shows good grade of semi-bituminous quality, and development consists of 200 feet of work. They have a railroad from the mines to river transportation. It is expected shipments will begin this week.

Ferry County.

Work has resumed on construction of the mill for the Bedie M. Co. at Bedie camp, near Republic, and men are also being put to work in the mine, says C. M. Fassett of Spokane, president. Work at the mine was suspended several weeks ago. All the material for a 10-stamp mill is on the ground.

Snohomish County.

Manager Braden of the American S. & R. Co. smelter at Helena, Mont., has twenty men at work at its smelter at Everett, but will increase the number to 200 and put the plant in full operation. Later the plant will be enlarged.

Stevens County.

The Syndicate M. & M. Co. has been incorporated by Spokane men to develop property in Meteor camp, on south half of Colville reservation, 12 miles southwest of Daisy. The company owns twelve claims between the Stray Dog and the Nonpareil, as well as the McDonald group, which was bought last year and which has been worked since by a co-partnership. The work has shown gold, silver and lead values. The officers are W. W. King, T. J. Coffman, D. S. Prescott and E. F. Waggoner.

WYOMING.

Laramie County.

The Colorado F. & I. Co., Pueblo, Colo., has made preparations to make large shipments of iron ore from its leased mines in Sunrise district. The bridges on the railroad between Hartville Junction and Sunrise have been rebuilt and the track put in condition. Since the shutdown at the mines six weeks ago a few men have been engaged putting the properties in shape for increased output. It is expected two trainloads of ore will be shipped to Pueblo daily.

FOREIGN.

AFRICA.

Rhodesia.

The total gold output of companies making returns to the Rhedesian Chamber of Mines at Bulawayo for month of December amounts to 18,750 ozs. (Matabeleland, 15,244 ozs.; Mashonaland, 3506 ozs.). The monthly returns for the year, compared with 1902, have been as follows:

	1903. Ozs.	1902. Ozs.
January	16,245	15,955
February	17,090	13,304
March	19,626	16,891
April	20,727	17,559
May	22,137	19,698
June	22,166	15,842
July	23,571	15,226
August	19,187	15,747
September	18,741*	15,164
October	17,918*	16,849
November	15,714*	15,923
December	18,750*	16,210
Totals	231,872	194,268

* Silver produced:—September, 4160 ozs.; October, 4231 ozs.; November, 4757 ozs.; December, 2573 ozs.

West Africa.

The Ashanti Goldfields Auxiliary, Ltd., has its two dredgers on the ground at Sekendi and they are being set up. They will conduct operations on the River Ofin.

BRITISH COLUMBIA.

Boundary District.

Boundary shipments for the month of January were:

	Tons.
Granby	44,520
Mother Lode	12,114
Emma	4,014
Oro Denoro	3,736
Athelstan	957
Senator	318
Total	65,659

Rossland District.

At Ressland operations were resumed this week at No. 1 mine of Le Rei Twe group. The product of the No. 1 will be shipped to the smelter at Grand Forks. The mine was closed down four months ago. The mine is said to be well developed, but its body of smelting ore was comparatively small. Production will be governed in a measure by capacity of the smelter to take the output. The No. 1 mine possesses bodies of iron ore, though these iron ores do not carry high enough values to permit of their being utilized in same manner as the higher grade pyrrhotite gold-copper ores, but the excess of iron over silica is such as to command favorable smelting rates from smelters to which this excess of iron is valuable for flux. The product of Le Rei Two concentrator is not as yet being shipped to any smelter under contract.

Slocan District.

A. Bigney, of Sanden, who has a lease and bond on the Majestic and Unexpected crown-granted claims on Payne mountain, reports cutting a vein of ore, varying from 6 to 12 inches wide. The length of the tunnel is 75 feet.

West Kootenay District.

Development work has been started on the Buffale group, near Peplar, under superintendence of H. White. It is intended to first run a 60-feet tunnel to tap the lead at 50 feet depth.

O. Sandberg, of Albert Canyon, W. E. Newcome, of Ferguson, and V. M. Westfall & Co., of Trout Lake, have bought the Lanark group of claims at Laurie. This group consists of fifteen crown-granted claims and fractions.

CANADA.

Alberta.

President A. C. Flummerfelt of the International Coal & Coke Co., operating at Coleman, says they shipped 100 tons of coal daily during December, which has been increased to 180 tons. Within eighteen months the company expects to increase its output to 2000 tons a day. In development work they have opened drifts to depth of 350 feet, 252 feet and 400 feet, respectively, the vein in the last named or main drift being 17 feet thick. The company has sixty-eight men in the mines, but is building houses, etc., and has 200 men on the payroll. Coleman is 6 miles east of Crow's Nest station, on the boundary between Alberta and British Columbia.

Nova Scotia.

Premier Murray reports that the revenue of the province for the year 1903 amounted to $1,243,581, of which royalties from mines yielded considerably more than half.

Yukon Territory.

Winter mining on the Klondike is in successful operation on No. 10 below, on Bonanza creek, near Dawson. A steam pipe heated by means of crude oil runs full length of a sluice box, by which the water is kept warm and the pay dirt shovelled into the sluices as in summer operations. At other points on the creek sluice boxes have been set up in drifts underground, protected from the cold air, warm water being used and re-used in washing gravel. The weather on the upper creeks has been comparatively mild, ranging from zero to 10 and 40 below.——There is talk in Dawson of an all-Canadian railroad from Dawson to points on the outside. The matter is mainly in the hands of the Governor of the Territory. Preparatory work is under way on the Klondike tributaries. It is said the mines are in better shape for production than ever before at this time. Supplies are abundant.——Favorable reports are received at White Horse from the new diggings on Beulder and Ruby creeks, 170 miles from White Horse. At depth of 6 feet, on Boulder, from 20 to 30 cents to the pan is obtained. In six days two men took out forty ounces on Ruby, while Boulder has paid three ounces a day to the man. Stations have been built and provisioned along the route from White Horse.

The Copper King mine, near White Horse, has made shipment of 150 tons of copper ore that also carries values in gold and silver. This mine will make regular shipments.

MEXICO.

Aguas Calientes.

The Aguas Calientes Metal Co., of Asientos, operating La Merced y Anexas group, in Ocampo district, 8 kilometers west from Cobre station on the Mexican Union railroad, in putting in a 110 H. P. steam turbine, an electric hoist, triplex electric pump, hoilers and other equipment. The group is being developed through two vertical shafts, one of which is two-compartment and down 260 feet. The other is single compartment and down 315 feet. The ore is said to run 5% copper, 8 ounces silver and 0.2 ounce gold per ton. The same company is also operating the San Simon y Anexas group, in same district, 1 kilometer south from Cobre station. Development on this group consists of one single-compartment vertical shaft, down 200 feet, and two tunnels, respectively 200 and 150 foot in length. The shaft is equipped with horse whim. Ore from the San Simon y Anexas group runs 5% copper with silver values. The two groups cover total of 44 pertenencias, says Albert Doerr, manager.

Chihuahua.

The Palmarejo & Mexican G. F. Co., at Palmarejo, reports December returns at: "Zapote" works, crushed 3100 tons and treated 2400 tons, producing $17,300 gold, $36,700 silver. The exponses were $42,650. The mill ran twenty-five days only.

W. D. Pearce of Chihuahua, manager of La Luz G. M. Co., operating at Maguarichic, reports the mill is completed and will be in operation next week. Ditch and pipe line to furnish water power is also being built.

The Corralitos M. Co. has closed down its mines at San Pedro on the Sierra Madre railroad from Juarez to Nuevas Casas Grandes. The concentrating plant at Juarez is also temporarily closed down.

A one-kilometer gravity double-track tram is being built for La Compania Ignacio, Rodriguez Ramos, S. A., at that company's Cigarrero mine, in Sierra Almaloya district. The capacity of the tram will be 250 tons from each of the two stations every ten hours.

Durango.

(Special Correspondence).—The International railway is extending its line north of Santiago de Papasquairo toward Guanacevi. This will open up several old camps in the country tapped by the railroad.——Three days on the trail, southwest from Santiago de Papasquairo, are the mines of the Bacis G. & S. M. Co., Ltd., an English company. Its holdings consist of 18 pertenencias. The values are found in sulphide of silver carrying gold. Ore is worked down to twenty-five ounces in silver per ton. The ore is carried from the mine to the mill by aerial tram. The mill of twenty stamps, crushing twenty-five tons of ore daily, is operated by water power piped from the Bacis river. The pipe line is 6000 feet long, decreasing from 30 inches in diameter at the river to 20 inches at the mill. Ten more stamps have been added and will be in operation next month. The company is also working a Bryan mill crushing twelve to fifteen tons daily. East of the mill excavating is in progress for machine shops. Some stringers of ore have been struck in this work which assayed twenty-one ounces in silver. Near the mill on a dike of porphyry and quartz bordering the river is the stone and cement shaft from which the Spaniards extracted their richest silver ores. W. S. Pearless is manager and A. J. Griffin assistant manager and chemist.——There are 200 men at work in development of the Cobre mines, 3 miles below Bacis. The company is owned largely by Hildebraudt & Co. of Durango, also Cushing & Walkup, owners of La Trinidad mine. The ore is a low grade sulphide of copper, with azurite. The vein runs 2½ to 5 feet in width. A concentrating plant of daily capacity of twenty-five tons has been completed for experimental treatment of the ores. L. Walkup is manager and T. Broidenbach is superintendent of the concentration plant.

Much development work is in progress near Huahuapa, which is on a branch of the Bacis river, toward San Dimas. The camp is comparatively a new one, but is shipping considerable high-grade silver and copper ore.

The silver mines at San Lucas, near Canatlan, on the International railway, north of Durango, are being operated by an American company.

Durango, Jan. 28.

Guerrero.

The Negociacion Minora Rosario y Anexas of Taxco is operating the Xhocotitlan and other claims in Alarcon district, 24 kilometers northwest from Naranjo station, on the Mexican Central Railroad. They cover an area of 120 pertenencias. Development consists of a double-compartment vertical shaft down 250 feet, one drainage tunnel driven 2000 feet, and crosscuts, drifts, etc., says the Mexican Investor. It is equipped with two Huntington 8-foot mills, five Frue vanners, one 15 H. P. single steam hoist, two steam pumps, four other pumps, one 8 H. P. engine, one 25 H. P. engine and two boilers with total of 38 H. P. The ore carries gold and silver and is said to run $40 Mexican per ton. B. Gorow is superintendent.

The Santa Cruz, Azianena and mines in the district of Santiago Papasquiaro, 95 kilometers from Parral, Chihuahua, owned and operated by the Restauradora M. Co., are developed by a three-compartment incline shaft, down 200 feet, four tunnels driven several hundred feet, and crosscuts, drifts, etc. They have a 50-stamp mill (950 pounds per stamp), two steam hoists, engine, hoilers, etc. A 100-ton cyanide plant is being built and the company is planning to put in Bryan mills also. The ore carries gold and silver values, says Manager H. H. Hughes.

Jalisco.

Douglas, Lacy & Co. of New York and Mexico City are sinking shafts on the Buena Ventura, San Salvador and Veta Grande mines. The Veta Grande is said to be producing ore which assays 16% copper, with $20 per ton in gold and silver. The vein is 5 feet wide. They have started work at another place on the vein, which they expect to connect by tunnel with the first one. The group is 6 miles south from Ezatlan and consists of twenty-four claims.

A company has been formed at Mexico City for development of the Esmoralda mines, in the municipality of Pihuano. The ores of this mine are said to carry 8% cobalt, 7% nickel also bismuth.

Mexico.

The Con. Gold Fields of South Africa Co. has taken over the Libertad group of mines between Tlalpujahua and El Oro. The Libertad adjoins the Dos Estrellas and the Union.

El Oro M.& R.Co., at El Oro, reports for month ending Dec. 31, the mill ran twenty-seven days, crushing 8567 tons, producing from 100-stamp mill, $106,913, producing from cyanide plant, $3698. Working expenses and development amounted to $63,075. The profit from the railway for the month was $9000. There has been expended on permanent improvements $35,279, including $26,009 on new mill.

Nuevo Leon.

The Bajan district, near Monterey, is reported shipping 2000 tons of ore monthly to the Monterey smelter. The Norias de Bajan, the Bonanza, the Mealy mines and the smaller mines of the district show an increase in tonnage, and generally a higher grade of ore with less zinc.

Oaxaca.

The Royal Crown M. Co. has taken over and is operating the Royal Crown group of claims, 3 miles southeast from Ocotlan, in Taviche district. The group consists of the Royal Crown, El Rey, La Reina and Prince claims, covering a total of 34 pertenencias. The Royal Crown was formerly worked by the Spaniards, but the workings (principally open cuts) are caved in. Recent development work consists of two shafts, besides crosscuts and drifts. At a depth of 115 feet in shaft No. 1 a crosscut driven northeast has cut the Veta Principal or main vein of the Royal Crown group, in 18 feet. In shaft No. 2 crosscuts northeast and southwest were run on the 82-foot level. At a depth of 115 feet ore running $40 per ton is said to have been opened up. Drifting north and south on this vein is in progress.

El Rosario M. Co., operating at Penoles, has denounced water rights which will be developed for power to run its mining and milling machinery.

F. Pimentel y Fagoaga of Mexico City, president of the Mexican Coal Co., operating near Puerto Angel, says additional machinery will be put in.

Sonora.

V. A. Lucier of La Colorada is developing a copper property 20 miles from Minas Prietas, and is preparing to put in machinery for a smelting plant.

The production of the Greene Con. C. Co., at Cananea, for month of January was 5,246,000 pounds of copper. The company has been increasing its production and this is the largest in its history. The first ingot of copper produced by the company was on May 27, 1902.

The Lucky Tiger Combination M. Co. of Bisbee, Ariz., operating near Cananea, is preparing to build a 25-ton smelting plant at its mine. A stamp mill and air compressor are also proposed.

Zacatecas.

The San Rafael Grande M. Co., allied with the Stilwell railroads, is working the San Rafael mines at Zacatecas and is shipping thirty cars of ore per week. The ore is shipped to Mapimi and Torreon smelters. December shipments amounted to value of $90,000. I. Ragaz is manager.

SPAIN.

The Finanz Chronik states that the revival of Spanish industries is especially noticeable in the mining and metallurgical branches. The production of silver ores, manganese, load and sulphur is increasing; that of copper has increased but little during the past few years; that of silver-bearing lead ore has decreased. The Somorrostro mine is producing 350,000 tons of silver ore per year.——The copper mines of Cordoba, Huelva and Sovilla, as well as those of Tharris and Rio Tinto, are well known. The last named has a production of $2,700,000 per annum. —— The load mines of Jaen, Murcia, Almeria and Linares yield an annual output of nearly 100,000 tons.—— Santander and Murcia produce 86,000 tons of zinc per year; Oviedo, Huelva and Sevilla, 30,000 tons of manganese; and Caceres, 19,000 tons of phosphorite.—— The principal quicksilver mines are in the Province of Ciudad Real. Among those, the most important one, operated by the Government, is the Almaden. The total production of quicksilver from this mine amounts to about 630,600 pounds per year.

Most of the metallurgical works are in the Basque provinces, especially in Bilbao. Among these are the Sociedad Altos Hornos de Vizcaya (which is a consolidation of the two smeltors, La Vizcaya and La Iberica), and that of J. M. Martinez de las Rivas, in Sestao.——The iron furnaces of Santa Ana de Bolueta, operated by transmitted hydraulic power, produce 3500 tons of pig iron and 4100 tons of manufactured iron per annum.—— The iron works of Aspete, 12 miles from Bilbao, have a yearly production of 3000 tons.

Huelva.

The Pona C. Co. at Nerva reports its December output at 9686 tons of copper ore, and shipments at 5742 tons. Precipitate, containing 100 tons of fine copper, was produced.

Personal.

W. M. KEENAN of Denver, Colo., is in California on business.

J. POUNDSTONE of Grimes, Cal., is in San Francisco, Cal., on mining business.

C. C. CLARK is superintendent of the Debentuary Co.'s mines at Gold Hill, Or.

J. F. BRANDES will leave Denver, Colo., next week on an extended European tour.

F. W. WILLIAMS of Seattle, Wash., is in San Francisco, Cal, on mining business.

R. F. BULLER of Hailey, Idaho, interested in Idaho mines, is in San Francisco, Cal.

L. O. RAY of Tonopah, Nev., interested in Nye county mines, is in San Francisco, Cal.

C. B. NEEL, superintendent of the Sumptor smelter, is in the East on business.

J. BALLARD is in San Francisco, Cal., from Camp Meeker, Cal., on mining business.

F. J. MCNAIR returned to Leadville, Colo., from a trip to Denver, Colo., last week.

H. B. GILLIS of Yreka, Cal., interested in Siskiyou county mines, is in San Francisco, Cal.

D. ROBERTS is manager of the Kelly tunnel at Georgetown, Colo., vice B. F. Kelly, resigned.

T. DERBY, superintendent of the quicksilver mines at New Almaden, Cal., is in San Francisco, Cal.

W. J. RULE of Sonora, Cal., superintendent of El Rico M. Co. at Tuttletown, is in San Francisco, Cal.

J. W. PIPER of Washington, D. C., is visiting his mining properties west from Dolores, Chihuahua, Mexico.

DR. JOS. HYDE PRATT of the Engineering Co. of America is in San Francisco, Cal., en route to Pyramid, Nev.

J. A. BUNTING of Bakersfield, Cal., owning oil properties in Kern and Fresno counties, is in San Francisco, Cal.

D. CLARK of Spokane, Wash., is manager of the American Eagle M. Co., operating the Eagle mine at Elk City, Idaho.

B. BLANCHARD, manager of the American C. Co. at Blanchard, Yavapai county, Ariz., is in the East on company business.

O. O. MCREYNOLDS of Denver, Colo., is superintendent of the Pelican, Dives & Seven-Thirty M. Co. at Georgetown, Colo.

W. TECHOW, former mill superintendent for North Pole M. Co., is manager of the Mountain View mine, near Sumpter, Or.

A. H. WILLETT of Portland, Or., is visiting the southeastern States on business connected with the Copperopolis M. Co.

W. H. BRAY is superintendent of the Federal Loan, Potosi-Orleans, Erie-Ontario and Gold Tunnel mines, near Nevada City, Cal.

H. WILSON of San Francisco, Cal., is in New York City in the interests of the Wildman-Mahoney mines of Sutter Creek, Cal.

J. N. ESSELSTYN has resigned as manager of the Mountain View mine, near Sumpter, Or., to take up general engineering work.

SUPERINTENDENT C. A. HOLLAND of the John Royal and Altadena mines returned to Columbia, Cal., last week from a short trip to the East.

T. E. SCHWARZ has returned to Denver, Colo., from Alma, Park county, Colo., after visiting the London mine for which he is consulting engineer.

I. MILLER, president of the Springfield-Nevada M. Co., returned to Olinghouse, near Wadsworth, Nev., last week from a business trip to Springfield, Mass.

M. BOEHMER will have charge of the Stratton's Independence mine, Victor, Colo., during absence of Superintendent Cornish, who is taking a vacation.

JOHN ROSS, JR., superintendent of the Wildman-Mahoney mine, has returned to Sutter Creek, Amador county, Cal., from a business trip to San Francisco, Cal.

B. F. KELLY, for the past three years manager of the Kelly tunnel at Georgetown, Colo., has resigned and has gone to New York. Later he will go to Mexico.

I. DAVIDOV, whose name has been connected with placer mining in Siberia, South America and Mexico, has established an office at 52 Broadway, New York City, as consulting engineer.

Obituary.

S. JONES, a mining man of Sumpter, Or., died at Portland, Or., on the 27th ult., of typhoid fever. Deceased was 49 years old and was largely interested in mining properties in Sumpter, being part owner of the Midway, the Lucky Boy, the Lula and other mines.

T. F. DELANEY, a mining man of San Francisco, Cal., was shot to death at Mojave, Cal., on Jan. 29th, by a party who, it is alleged, lay in wait for Delaney and fired at him from behind. No motive for the crime is known. Deceased was a native of San Francisco, and 27 years of ago.

THOMAS RILEY, a Colorado mining man, died at Idaho Springs on the 8th inst., of miners' consumption, with which he had been a sufferer for several years. He was 49 years of age and a brother of G. Riley, mayor of Idaho Springs, with whom he discovered and developed the Franklin group of mines, which are being operated by the Gem consolidation.

Commercial Paragraphs.

W. W. ELLIOTT AND F. M. DRESCHER, consulting engineers, have formed a partnership at Prescott, Ariz.

THE Deitz Electric Drill Co., 1614 Blake street, Denver, Colo., recently shipped one of their drills to Jamestown, Boulder county, Colo.

THE Nichols Steam Generator Co. has opened offices and shops at 151 New Montgomery St., San Francisco, Cal., where they will handle the instantaneous steam generator for house heating and power purposes.

THE Union Gas Engine Co. of San Francisco, Cal., brought suit on the 1st inst. in the United States Circuit Court against the Standard Gas Engine Co., charging the latter with infringement of the gas engine patents belonging to the former. Because of the alleged infringement, the Union Gas Engine Co. asks for an injunction and damages against the Standard Co.

MARTIN HARDSOCG has returned to Ottumwa, Iowa, from a three months' trip of personal investigation of his drills in Western and Southwestern mines, and has decided to make extensive arrangements to put the "Little Wonder" air hammer and rock drill on the market,

deeming the field favorable for the introduction of such a tool.

THE Gardner Electric Drill & Machinery Co., through their Denver, Colo., branch, E. C. Means, manager, has recently installed two of their No. 15 drills in the McAlpine G. M. & M. Co. property, Chinese Camp, Tuolumne county, Cal., which are giving satisfaction from reports received from there. Mr. Means reports a fairly good business in their particular line.

JOHN A. ROEBLING'S SONS CO., continually extending their sphere of influence, have lately established a store at 313 First Ave. South, Seattle, Wash., where they carry a full line of wire rope, bare and insulated copper and iron wires, wire cloth and netting, telegraph wire, etc. The parent house at Tronton, N. J., where the works are established, has efficient representation by numerous branch establishments, prominent among which are those at 117 Liberty street, New York City; 173 Lake street, Chicago, Ill.; Denver, Colo.; 25-27 Fremont street, San Francisco, Cal.; Ravena and Alameda streets, Los Angeles, Cal.; First and Stark streets, Portland, Or., and now the new Seattle establishment.

Books Received.

"Mineral Tables, for the Determination of Minerals by Their Physical Properties," is the title of a work by Arthur S. Eakle, Ph. D., assistant professor of mineralogy at the University of California. This useful little book is intended as an aid to those studying mineralogy and to assist students in more quickly determining a mineral by its appearance and general physical characteristics, in the field or in the laboratory, in the simplest manner. Practice of this sort tends to develop the habit of close observation, and enables the student to become familiar with minerals more quickly than in any other manner. The tables include all of the common minerals and a few of the more rare ones; 73 + 111 pages. Cloth, $1.25. John Wiley & Sons, New York, and Chapman & Hall, Ltd., London.

Trade Treatises.

The Buff precise transit is described in detail in a copyrighted catalogue issued by the Buff & Buff Mfg. Co., Jamaica Plain, Boston, Mass., and worth reading by any engineer.

A 24-page catalogue from S. H. Harmon Lumber Co., 534 First or 42 Market street, San Francisco, Cal., givos illustrated description of the oil, water, wine, mining, stock, silo and rectangular tanks that they manufacture and supply.

Elegantly arranged and of manifest value is the latest pamphlet, "Giant Air Compressors and Rock Drills," issued by the Compressed Air Machinery Co., 24-26 First St., San Francisco, Cal. In its 80 pages are illustrated description of the air compressors, drills, pumps, engines, pneumatic tools and efficient labor-saving mining devices manufactured and sold by that company, several of them being new and all descrving notice. A copy of this fine publication will be sent to any address on request.

Notices of Recent Patents.

Among the patents recently obtained through Dewey, Strong & Co.'s SCIENTIFIC PRESS U. S. and Foreign Patent Ageney, the following are worthy of special mention:

AUTOMATIC FLUSHING TANKS. — No. 750,955. Feb. 2, 1904. Joh E. Erlcson, San Francisco, Cal. This invention reintes to a tank or receiver such as may he employed for flushing and like purposes. The object of the invention is to provide a receptacle for holding a given quantity of water to approximately fill the receptacle with water from a source of supply under pressure which will be sufficient to force the water into the receptacle and compress a body of air in the upper part thereof, which afterwards serves to force out the limited body of water under pressure of the compressed air within the tank.

MALT MAKING MACHINE.—No. 751,026. Feb. 2, 1904. H. J. Sulzen, Sacramento, Cal. The object of this invention is to provide a machine which may be propelled and guided over the floor as desired and which is adapted to agitate, lift, aerate and collect the malt or redistribute it upon the floor. It consists generally of plows and means for propelling them along the floor so that they will take up and turn the malt, and elevators or earriers hy which the malt is raised and subjected to a hlast of air and afterward again discharged and distributed upon the floor.

DEVICE FOR TREATING TEGUMENTARY TISSUES. —No. 751,194. Feh. 2, 1904. A. S. McCutchan, Oakland, Cal. One-half assigned to John Yule, of same place. This invention consists of a container, with means for applying it to the tissues to he treated, so as to form a close joint against leakage without undue constriction or pressure on the parts to he treated, a means for supplying said container with oxygen gas, and means for regulating its size. In conjunction with this I have shown means for admitting light and means for directing light into the container and also a device by which static electricity may he used in conjunction with the oxygen and light and means for producing what is knowa as the "static breeze."

CENTRIFUGAL WASHER FOR FISH DRESSING MACHINE.—No. 751,388. Feb. 2, 1904. A. J. Farmer, San Francisco, Cal. Assigned to the Canners' Machine Co., of San Francisco, Cal., a corporation. This invention relates to improvements in fish-cleaning machines and particularly to an improved washer for cleansing the cavity of the fish after the fish have been split open and the entrails and soft portions removed. It consists in substituting for the usual stationnry jet pipes a rotary washer, operating within the cavity similarly as the cleaning brushes. The particular class of fish-cleaning machines for which it has been designed comprises those machines which handle and dress the larger fish, such as salmon.

SIDEHILL HARVESTER.—No. 751,111. Feb. 2, 1904. A. W. Severance, Walla Walla, Wash. Assigned to Holt Mfg. Co., of Stockton, Cal., a corporation. This invention relates to an apparatus for harvesting grain and the like which is especially designed for use upon sidehills and in such a manner that the thrashing and cleaning mechanism of the apparatus may be maintained substantially horizontal transversely of the machine, so that the grain delivered into that portion of the machine will not he bunched up at one side or the other.

New Patents.

DEWEY, STRONG & CO.'S SCIENTIFIC PRESS PATENT AGENCY, 330 Mnrket St., S. F., has official reports of the following U. S. patents issued to Pacific Coast inventors:

FOR WEEK ENDING FEBRUARY 2, 1904.

750,705.—PIPE WRENCH—E. J. Bates, Bakersfield, Cal.
751,251.—KNIFE—J. C. & G. E. Bollinger, Olympia, Wash.
750,941.—TOOL DRESSER—J. S. Brown, Los Angeles, Cal.
751,062.—DRILL—C. Erickson, Bremerton, Wash.
750,955.—FLUSHING TANK—J. E. Ericson, S. F.
751,388.—CENTRIFUGAL WASHER—A. J. Farmer, S. F.
751,064.—GARMENT SUPPORTER—F. Ferguson, Santa Rosa, Cal.
751,360.—JOINTER—C. F. Frazee, Portland, Or.
750,846.—PUMP—T. R. Goth, S. F.
751,365.—OIL BURNER—Hess & Williams, San Jose, Cal.
750,978.—GARMENT SUPPORTER—J. E. & I. O. Josephi, S. F.
751,309.—LIFTING JACK—L. O. Lander, Lisabuela, Wash.
751,085.—GAS APPARATUS—L. P. Lowe, S. F.
751,194.—TREATING TISSUES—A. S. McCutchan, Oakland, Cal.
751,322.—LOGGING DEVICE—G. Moore, Monroe, Wash.
751,092.—OIL BURNER—D. H. Mosteller, S. F.
751,334.—SEWING AWL—T. O'Shaughnessy, San Jose, Cal.
751,405.—INDICATOR—G. D. Palmer, Powell Valley, Or.
751,001.—CAN OPENER—A. M. Parker, Los Angeles, Cal.
751,410.—JAR COVER—H. A. Porteous, Hemet, Cal.
751,106.—LAND SCRAPER—C. E. Reed, Sunnyside, Wash.
751,111.—HARVESTER—A. W. Severance, Walla Wnlla, Wash.
751,026.—MALT MACHINE—H. J. Sulzen, Saeramento, Cal.
751,225.—ELEVATOR—F. B. Van Cleave, Echo, Or.
750,923.—DRAWING TOOL—F. H. Wheelan, S. F.
751,364.—VALVE—G. R. Wilehart, The Dalles, Or.
751,426.—HAIR PIN—W. F. Zwick, Seattle, Wash.
36,765.—DESIGN TOY BANK—S. W. Knighton, Portland, Or.

Latest Market Reports.

SAN FRANCISCO, February 12, 1904.

METALS.

SILVER.—Per oz., Troy: London, 26⅛d (standard ounce, 925 fine); New York, bar silver, 56⅜c, refined (1000 fine); San Francisco, 56⅜c; Mexican dollars, 43@44½c San Francisco, 43½c New York.

COPPER. — New York: Standard, $12.50; Lake, 1 to 3 casks, $12.50; Electrolytic, 1 to 3 casks, $12.25; Casting, 1 to 3 casks, $12.12½; San Francisco: $15.00. Mill copper plates, $17.00; bars, 18@24c. London: £55 12s 6d spot per ton.

Copper remains dull and quiet. Europe reports heavy buying, but in the United States the demand is as yet nominal; consequently the price is slightly lower and shows no signs of immediate change in either direction.

LEAD. — New York, $4.45; Salt Lake City, $3.50; St. Louis, $4.25 San Francisco, $4.50, carload lots; 4⅜c 1000 to 4000 lbs.; pipe 6½, sheet 7, bar 5½c; pig, $4.85. London: £11 13s 9d ₱ long ton.

SPELTER.—New York, $5.00; St. Louis, $5.00; London, £21 15s ₱ ton; San Francisco, ton lots, 6¾c; 100-lb. lots, 7c.

TIN.—New York, pig, $27.50 @ 28.00; San Francisco, ton lots, 30½c; 500 lbs., 31c; 200 lbs., 31½c; less, 32½c; bar tin, ₱ lb., 35@37½c. London, £124 7s 6d spot.

PLATINUM. — San Francisco, crude, $18.00 ₱ oz.; New York, ingot, $19.00 ₱ Troy oz. Platinum ware, 75 @ 82c ₱ gram.

QUICKSILVER. — New York, $46.50@47.00, large lots; London, £8 7s 6d; San Francisco, local, $44@45 ₱ flask of 76½ lbs.; Denver, $48.00. Export, $42.00@42.50.

SITUATIONS WANTED.

ASSAYER AND METALLURGIST WITH OUTfit wishes position. Address "L.", this office.

AN ASSAYER, CHEMIST AND MANAGER of mill and cyanide plant is open for engagement; will render services for salary or interest. Address "Metallurky," eare Min. and Sci. Press.

EXPERIENCED DRAUGHTSMAN AND DEsigner wants position with company building or operating gold dredges. Adr. "Dredge," this office.

EXPERIENCED SUPERINTENDENT, ENGIneer, Metallurgist; technically and liberally educated; 15 yenrs handling men and machinery of smelters, mills and mines. See testimonials. Address Prof. Stickney, Mountain View, Cal.

GRADUATE CIVIL ENGINEER, OPEN FOR engagement; 14 years experience; A1 draughtsman. Address "Cappella," this office.

MILL AND SMELTER SUPERINTENDENT, at present disengaged, wishes similar position with responsible company; college graduate with varied experience. Best of credentials furnished and required. Address "Gluckauf," eare this office

MINING ENGINEER WITH EXTENSIVE EXperienee in coal and placer mining desires position. Address "Lulu," this office.

MINING ENGINEER AND METALLURGIST, technical graduate, with large experienee as superintendent, manager and consulting engineer of mines and mills, desires a position. Best references. Speaks Spanish fluently. Address "Ingeniero," care of Mining and Scientific Press.

NORWEGIAN GRADUATE ENGINEER would like position with land company. Can take charge of work in field or office. Ten years experience. Address "Norway," this office.

WANTED—POSITION WITH MINING COMpany as manager or assistant. Examinations, surveying, assaying; also familiar with drift and hydraulic mining. Best of references. Address W. H. J., this office.

YOUNG GRADUATE OF GOOD MINING school wants position with reliable mining company. Not afraid of hard work. Object, advancement. Address "Advaneement," care of this office.

HELP WANTED.

WANTED—MINE SUPERINTENDENT OF EXperience, who thoroughly understands handling of gold-hearing ores and management of mine and men. Must he willing to take part of salary in stock of company until mine is on paying basis. Mine is in Californin. Only thoroughly competent men need apply. References required and given. Address G. Mines, care of Mining and Scientific Press, San Francisco, Cal.

WANTED.

WANTED---One each, 50 and 100 H. P. Belted Air Compressors; One Gates or Austin Rock Crusher. Address "Cash Buyer," care of this office.

REDFIELD
HAND POWER ROCK DRILLS.

OTTAWA, CANADA, Dec. 16, 1903.

MESSRS. REDFIELD DRILL CO., Denver, Colo.

Dear Sirs:—As I have been in the mica mining business upward of 16 years, and have handled nearly all of the rock drills that have been put on the market, and having been general mine superintendent for the Wakefield Mica Co. Ltd. for the last six months and have had one of the Redfield Hand Power Rock Drills at the Kodock mica mine, and having operated your drill in various kinds of rock, I am now thoroughly convinced that your drill is as perfect as is possible for a hand power rock drill to be, and if operated by practical miners will reduce the cost of rock drilling. I might say I have had two Jackson hand power rock drills operating in the same mine and find that your drill has done more work than both the Jackson drills in the same rock.

Yours truly,
(Signed) K. B. HOLLAND MICA CO.
554 Gladstone Ave., Ottawa, Canada.

FOR SALE BY
Hammond Manufacturing Co.
100 First St., PORTLAND, ORE.

ALL STEEL CONSTRUCTION.

Guaranteed to do double the work of any other hand-power rock drill on the market. Write us for details and catalog.

MINING AND SCIENTIFIC PRESS.

Whole No. 2274.—VOLUME LXXXVIII. Number 8. SAN FRANCISCO, CAL., SATURDAY, FEBRUARY 20, 1904. THREE DOLLARS PER ANNUM. Single Copies, Ten Cents.

Mines of Searchlight, Lincoln County, Nev., and Vicinity.

Searchlight is 25 miles in a northeasterly direction from Manvel, Cal. Searchlight, as well as the camps of El Dorado canyon, Cottonwood Springs and Good Springs in Lincoln county, north of Searchlight, is tributary at present to Manvel. The proposed line of the San Pedro, Los Angeles & Salt Lake Railroad, now building from Salt Lake City, Utah, will be the means of increased activity in opening up the entire section north of Searchlight. In the McCullough mountains, north of Searchlight, are the turquoise mines of the Simmons group. The turquoise occurs as veinlets and nodules in dikes which cut through the main mass of porphyry of the mountains.

The fame of Searchlight rests largely upon the record of one mine—the Quartette—owned by the Quartette M. Co., a close corporation, principally of Eastern men. They have opened up the mine down to the sixth and seventh levels. About forty tons a day are being taken out, and the output of the 10-stamp mill is stated to be $50,000 per month. This mill is operated on the property, with water supplied from the mine. The company has a 20-stamp mill near the Colorado river, 18 miles east, and a narrow-gauge railroad transported the ore for its operation, but at present it is shut down. Superintendent T. J. Harrington states that it will be started again in the spring. Considerable ore is blocked out, but there is no cessation of development work. The strike of the miners a few months ago temporarily stopped all work in the district, and it has not yet resumed its former output.

Searchlight, Nevada, Looking East.

The Southern Nevada Co., of which F. Perew is manager, is progressing with satisfactory results. Its mine, the Rosebud, is a flat ledge, covering a low hill and cropping near the summit. This slopes off gradually in all directions and has been quarried as far as possible. It is now being worked by inclined shafts. Considerable development work is being carried on besides the regular production of thirty-five tons of ore a day. The mine is about a mile from the company's 10-stamp mill. The ore is hauled in wagons, and by an automatic dumping arrangement, dropped into cars and run into the mill by gravity. The mill was so placed on account of an abundance of water found in a shaft sunk there in prospecting. It is in such quantity that no attempt is made to save it for reusing and it flows across the stage road, a mile distant. There are 18,000 to 20,000 tons of tailings on the dump and a cyanide plant will soon be installed to rework them.

Head Frame, Quartette Mine, Searchlight Nevada.

The Duplex Co., owning the original discovery near the town of Searchlight, is not uow operating, though it is said they will resume this spring. They also have a 10-stamp mill.

The Good Hope mine, owned by P. D. Carper of Los Angeles, Cal., is between the Duplex and the Quartette and is carrying on development work steadily with encouraging results, as is also the Cyrus Noble mine, owned by G. E. Otis of Redlands, Cal. The latter is west of Searchlight, and near the level of the desert. It has no mill as yet, but is yielding ore which is hauled to Manvel and shipped thence by rail to El Paso, Tex. Many other smaller prospects are being developed in the district, which covers a chain of low hills about 3 miles in extent, rising abruptly from the floor of the desert.

Mill of Southern Nevada Co., Searchlight, Nevada.

Eighteen miles southeast of Searchlight, and 7 to 10 miles from the Colorado river, is Newberry Mountaiu district, which, while as yet in the prospect stage, promises well. The principal development is being done by the Empire M. Co., headed by W. H. Fuller of Los Angeles, Cal., and owned mainly by Easteru men. Superintendent A. A. Ross is sinking a shaft on the Mountain Jewel claim, in which water was found at 65 feet, and while it is being put down in high-grade ore, the water is interfering with operatious. This water will be used to ruu a 10-stamp mill which they propose to erect in the summer. There are seventeen claims in this group. On three, the Tar Heel, Empire and Badger, for a distance of 4500 feet crops a ledge of high-grade quartz which is being opened up in several places by shaft and tunnel. It is so situated that the ore can be mined and milled at a low cost.

Northerly from Searchlight, in the Spring Mountain section, are the lead-silver mines of the A. J. Campbell estate, covering a total of thirty patented claims. The principal producers of the group were the May Belle, Ruth, and May Kirby mines. Little work is being done there at present. A few miles west of Spring Mountain district are Cottonwood Springs and Good Springs. Near Good Springs, a fiud of cinnabar has been made by J. C. Armstrong, and it is being opened up as the Red Cloud claim. The cinnabar is said to be associated with free gold, and occurs on the hanging wall of a 50-foot porphyry dike which cuts through the limestone.

A SOMEWHAT anomalous condition prevails in the Transvaal, South Africa, where recently a petition signed by over 45,000 white men, representing over 70% of the entire white male populatiou—about 15,000 men in Government service not voting—praying the Government to admit Asiatic unskilled laborers to the Transvaal to work in the miues. The Australian and New Zealand officials have doue all in their power to prevent the mine owners aud the Transvaal government from importing Chinese or other Asiatics, having had experience with this class of labor themselves; but the resident Australians of the Transvaal have remonstrated with their home government, telegraphing that representative Australian business men and professional men resident in the Transvaal strongly protest against the interference with the plan of Asiatic importation. At present the mines are worked chiefly by uative Africans imported from Portuguese territory. The natives from British territory refuse to work down in the mines, although they are there iu the country in great numbers. It is probable that, as it is evident that the great majority of the white residents of the Transvaal favor Chinese labor in the mines, these will soon replace the Kaffirs and other negro tribes which have heretofore done the work.

WHILE the requirement that mine hoisting eugineers shall pass an examination by a proper authority is not geuerally in force in the West, and is usually considered unpopular, if not unnecessary, still the fact that a man understands that he will have to be examined cannot fail to have a beneficial result, as he will then gain all the informatiou about hoisting engiues, and the requiremeuts of miue hoists generally that he can possibly obtain, and the result is a better engineer than would otherwise result.

Sensible Mine Rules.

The code of regulations which has recently been posted by the Federal Mining & Smelting Co. about its mines and works at Wardner, Burke and other mines in the Cœur d'Alenes of Idaho, is an instance worthy of more thau passing notice. It consists of thirty-five rules regulating the conduct of the men employed by the company, and the use by them of the company's property. The code is published elsewhere herein verbatim, as it is considered of sufficient interest and importance to miners everywhere. The first requirement is that all employes must "read" the rules before going to work for the company. This signifies that the miners employed shall be able to speak or read the English language, but this requirement is weakened somewhat by Rule 6, which requires that some other person shall read the rules to those who are unable to read them for themselves. In some instances mine managers have made a rule that every man going underground shall be able to speak Euglish intelligibly. This is calculated to reduce the likelihood of accident, but a faithful observation of the requirements of the rules of the Federal Company, whatever the nationality of the workmen, must result in decreasing the probability of accident to a minimum. Without doubt the rules were compiled after careful thought, and by a manager thoroughly acquainted with the dangers of underground mining. He calls attention to the unexpected dangers which lurk in many places, in passing raises or winzes, in the open stopes, at the face, in the bottom of the sinking shaft, in every portiou of the mine, the dangers likely to be encountered are anticipated and pointed out, thus educating the inexperienced, cautiouing the old hands, and restraining the careless. The paragraphs dealing with blastiug and missed holes are pertinent aud worthy of observance throughout the mining regions everywhere. The rules indicate a familiarity with the careless practices of miners, which not infrequently result fatally. Among these are the custom of carrying nitro powder in the boot legs, detonating caps in the pocket, smoking about the loading bench and carrying lighted candles about when preparing fuses and powder for blasting. The habit which some men have of clinching caps onto the fuse with the teeth is not mentioned, probably in the belief that no sane man will do such a thing, proper nippers being supplied for this purpose, yet not a few miners do this commonly, long escape from harm leading them to think there is no danger in the practice. The section referring to "missed holes" is also as complete as it seems possible to make it. The missed hole is an element of great danger and it cannot always be detected, for when a round is fired a uumber of reports may be counted which corresponds with the number of holes "spit," and still there may be a "cut-off" hole in which there remains sufficient powder, should it explode by drilling into it, to kill half a dozen men, but the cut-off hole is hard to locate and is usually unsuspected. There are some elements of danger in the life of a miner which cannot be altogether eliminated. The rule requiring the hoist engineer to send an empty cage or skip down the shaft and pull it back to ascertain if the shaft is free from obstruction before lowering men into the mine, is a new and unusual practice, but one which might well be adopted, as a precautionary measure. The rule indicatiug the maximum number of men that shall ride on certaiu cages is timely, as if left to themselves when coming off shift the men will often overcrowd the skips or cages, and many serious accidents have resulted from the practice. The section requiring daily inspection of the shaft, ropes and machinery is essential, but at mauy mines is neglected altogether, and these departments are considered safe if they are found in good condition on monthly or bi-monthly inspection. There are many mines where the hoisting ropes never receive an inspection of any sort until evident signs of weakuess present themselves. Then the rope is turned "end for end." This is well enough if all of the weak portions be on the reel with several additional turns for safety, but if the weak portion goes beyond the reel then the danger is greater than before. It is manifestly safer to cut off 200 or 300 feet altogether of the rope than to turu it end for end.

On the whole the regulations of the Federal Company seem to be as comprehensive and as sensible as any rules of the kind introduced elsewhere, and are superior to some others. In every paragraph the company evinces its aim and desire to protect the men from accident, though it is evident from carefully reading the regulations that the greater number of accidents anticipated are likely to be the result of carelessness on the part of the miners themselves.

Just at this time, Colorado miners are agitating a proposition to have legislation enacted in that State which shall make the reoccurrence of a disaster similar to that which recently occurred at the Independence mine, at Victor, an impossibility. There are many things in the operation of a mine which fall naturally within the province of State legislation, and a number of the rules of the Federal Company above referred to, have already been made subjects of legislative action, in several States. When State legislation is contemplated which shall influence the mining industry, and particularly the practical operation of mines, it would be the part of wisdom for the legislative committee having the matter in hand to call upon a number of the most experienced mining men in the State for advice on the subject and thus avoid unuecessary complications, encumbering the statute books with meauingless laws. Experienced mining men know what is required and what is best for the operation of a mine. These things are often unfamiliar to men composing legislative bodies, and however good their intentions, they fail sometimes to accomplish the object aimed at.

Prospectors' Opportunities in Alaska.

There are numerous reports of new discoveries of placer gold in Alaska and in the Northwest Territory, which will probably attract many adventurers the coming summer season. Preparations are being made by many to take advantage of the first steamers going north. This northern field is one of the most extensive undeveloped mineral regions known, and it holds out a promise of possible success to those having sufficient means to properly equip themselves and to open claims which require the expenditure of time and money, but unfortunately there are many going who have neither means nor experience, nor the necessary physique to endure the hardships of a pioneer's life in the Arctic regions. For these latter one is inclined to predict failure, if not disaster, but of the many who have preceded them in past years some did well, and it was not always those best equipped who succeeded. The recent discovery of a second beach at Nome, higher than the present beach, and at a distauce of half a mile or more from the shore line, indicates that after four years of active prospecting in that district there are still good chances. In the interior of Alaska there are extensive gold-bearing gravel deposits, but these for most part must be opened by men of large means.

THE success which has so frequently attended the efforts of leasers in the Cripple Creek, Colo., district has resulted in the mine owners making new rates and terms in leasing their property. It is stated that hereafter in most cases the minimum royalty will be 25%, with a higher sliding scale for ores above a stated value. They have determined also to reserve for themselves the privilege of working the blocks immediately above or below any new finds made by leasers in their explorations. Notwithstanding these new and somewhat arbitrary conditions imposed, miners are still eagerly seeking the privilege of leasing in many of the noted mines, the richness of which heretofore have made numerous leasers wealthy.

AS a result of the recent disaster at the Independence mine at Victor, Colorado, the Commissioner of the State Mining Bureau has instructed his deputies to notify mine managers throughout the State to make such changes as are necessary in their shaft equipment and miue operation as were recommended by the special committee of inquiry appointed by him to investigate the cause of the accident at the Independence mine. It is said 150 mines will be required to make material changes to conform to the new requirements. Among other changes the mines will be required to place extra "chairs" in the head frames, and devices on the cages to prevent overwinding.

CONCENTRATES.

THE sample of rock from southern Oregon labeled "kaolin" is not clay, but infusorial earth.

LANDS containing clay, kaolin, etc., on the public domain are subject to location under the placer laws. The location is made in the same manner as other locations.

IN 1901 the Legislature of Nevada passed a law providing for paying a bounty to the first person discovering and producing petroleum oil or natural gas in that State.

THE rock specimen from Temaxcaltepec, Mexico, is specular iron (a variety of hematite). It is slightly magnetic, probably due to admixture of magnetite. This ore is sometimes gold bearing.

SOME porphyries have the same chemical composition as feldspar, due to the admixture of various feldspars, such as orthoclase and albite, which is possible without changing the crystal form of the mineral.

THE rock specimen from Rye Patch, Nev., is granular quartz, containing molybdenite, the sulphide of molybdenum. The molybdenite can be concentrated. The rock also contains a small amount of iron sulphide.

IN roasting sulphide copper ores for leaching by acid solutions, it is easy to carry the roasting process too far, forming oxides instead of sulphides of copper, and the oxides leach very slowly, rendering what might otherwise be a profitable operation a failure.

WHEN driving a drift, it should be cut the full size it is intended to have it. There is no economy in driving a small drift and subsequently enlarging it. The same applies to shafts and all other mine cuttings, excepting stopes, which should be worked in blocks.

THE three samples from Tucson, Ariz., are: No. 1, marked "clay," infusorial earth; No. 2, marked "spar," calcite, colored by iron and manganese; No. 3, marked "iron ore," magnetite, with small amount of pyrite, small amount of copper sulphide present.

WHERE rock is broken in an open cut, either ore or waste for filling, if the rock is to be sent down through a mill hole located at the lowest portion of the cut, a grizzly of heavy timbers should be placed over the shaft to keep large rocks from passing down and jamming the chute below.

A CHARACTERISTIC of aluminum is that it is not attacked by nitric acid at boiling heat. The only other metals capable of thus resisting the action of nitric acid are gold and platinum. Hydrochloric acid, which alone does not affect gold or platinum, dissolves aluminum readily, converting it into aluminum chloride.

THERE are about 180 sticks of ¾-inch nitro powder in a fifty-pound box, about 135 sticks of 1-inch powder and about 100 sticks of 1¼-inch powder. The powder is net weight, the box and sawdust packing not being counted by the manufacturers, though these add materially to gross weight and cost of transportation.

IN placing the column pipe for a mine pump, flanges are superior to the ordinary couplings, as by their means the pipes can be placed or removed without turning by means of wrenches, thereby lessening the work in the shaft, and they also afford a substantial support for the pipe line by placing "yokes" at proper intervals, the flanges resting on the "yokes."

INFUSORIAL EARTH, or diatom earth, is an aggregate of the skeletons of the microscopic plants called diatoms; is white, yellowish and light brown. The material composing these beds are almost wholly silica and contain little aluminous matter (clay). It is used chiefly for polishing powder. Some manufacturers of nitro powders use this material in the manufacture of dynamite.

THE greatest pressure upon the pipe line into Virginia City, Nev., is 1720 feet, equivalent to 846.48 pounds per square inch. The pressure of a narrow, vertical sheet of water is proportional to its height. The pressure of a sheet of water but a foot wide against the wall of a vertical dam is as great as though the water extended back for miles. This is known as the hydrostatic paradox.

THE cost of excavating earth should be estimated and fixed by the cubic yard excavated, whenever the material removed is to be dumped into a fill. Various kinds of earth and rocks settle in different degrees of compactness and may make more or less than had been estimated. If the price is fixed upon the amount excavated there can be no controversy as to the amount in the embankment.

THE strength of potassium cyanide varies considerably. In practice it contains from 98% to 125% of cyanide (estimated as the potassium salt), but the higher grades generally contain a quantity of sodium of cyanide, which when refined and pure contains 53% cyanogen—potassium cyanide containing but 40%. Consequently a pure sodium cyanide would appear to contain 132.5% potassium cyanide—that is, the equivalent to that amount.

SELENITE resembles mica when in thin transparent sheets. It is sulphate of calcium (gypsum). To determine between mica and selenite, place a piece of the mineral over a fire, and if it be selenite it will quickly become white and opaque. Mica is little or not at all affected by heat. There are also minerals containing selenium referred to as "selenites," but these are ores containing usually copper, silver and lead as well as selenium and are not to be mistaken for either gypsum or mica.

TETRAHEDRITE (gray copper) is a compound of copper, antimony and sulphur, as essential constituents, but often also contains various other substances, including arsenic, mercury, lead, iron, etc., and it is often rich in gold and silver. When the luster is brilliant, it may sometimes be mistaken for some varieties of tellurido, but the latter are much softer than gray copper. Tetrahedrite is decomposed by nitric acid. The tellurides, when powdered and treated with sulphuric acid, color the solution purple.

"LEAD POISONING" in lead mines is due to the miners inhaling the dust in the mine workings, caused by drilling, shoveling, etc. Cases of this kind occur in dry lead mines, where the ores are oxidized—carbonates, sulphates, oxides, etc., and is seldom heard of in mines producing galena, unless the men drink the water in the mine, which may contain various mineral salts detrimental to health, though the water may be cold and perfectly clear and pleasant to the taste. Arsenic is often present in mine water.

IF John Doe was still in the employ of the Gold Hill Co., work done under his direction during the latter part of 1903, whether paid for or not, would inure to benefit of the company. If, however, he was a mere trespasser, any work done by him, or under his direction, would in no way benefit the company, and as they had not commenced the assessment work by January 1, John Doe could legally locate the property and claim everything on it. If John Doe were still in the employ of the company, or a co-owner with the other owners, he could not relocate to the disadvantage of his partners.

THE expansion of a steam pipe line conducting steam 100 feet to a pump in a mine shaft will be from 4 inches to 6 inches, and allowance must be made for this or the fittings will be broken, and this usually occurs at the pump, where the pipe connects with the cylinder. For this reason a slip joint is advisable. Slip joints are also advisable on the column pipe. Where the latter is put in place the smaller pipe, which "telescopes" into the larger section, must be placed uppermost, or any grit carried in the water being pumped out will soon fill the space between the two pipes and the interior pipe will become jammed.

EVERY SHAFT should have a protecting hand rail about the collar, to prevent persons from accidentally falling into the shaft. Such a rail can be arranged by setting posts at the corners and opposite the dividers. The rail need only be secured at one end, and free to move, as on a hinge. By securing the bars at the corner posts by passing an iron rod through both post and bar, the other end may be raised out of the way or lowered to its place on the adjacent post. This admits of handling timbers, changing skips, the passage of men and materials to and from the mine, and also insures comparative safety.

THERE are several kinds of mica. The micas are all scaly minerals, of which muscovite (the ordinary colorless transparent mica of commerce) and biotite (the black mica of granite and other rocks) are the most charactoristic type. In addition to these there are paragonite (sodium mica), lepidolite (lithium mica), zinwaldite (lithium-iron mica), phlogophite (magnesium mica), lepidomelane (iron mica), roscoelite (vanadium mica), alurgite (manganese mica), sericite (a fine scaly mica of silky luster), mariposite (magnesium mica colored by chromium oxide), uranium mica, and a number of others which are rare.

SPLIT lagging, if made of good timber, is superior to sawed lagging and is usually thicker. The cost of split lagging varies in different camps, being usually about $70 per 1000. This is equivalent to sawed lumber at $14 per 1000, for the space covered by the two kinds of lagging, if the sawed lagging is a little under 5 feet in length. If the lagging is being driven the sawed kind must be at least 6 feet in length, while the split lagging is usually either 5 feet or 7 feet long. If too long it is cut off and the ends used for blocking, etc. For wet shafts in soft ground where the material will run if given a chance the sawed lagging is preferred.

IT requires from 4000 to 6000 gallons of crude oil, according to the character of the material, to sprinkle a roadway 16 feet wide. The best practice is to sprinkle the roadway liberally the first time it is gone over, and during the dry season to sprinkle it two or three times lightly. If the roadway is properly treated it soon forms a firm, solid surface, with no dust, but generally, for reasons of assumed economy, too little oil is used, and the result is not as satisfactory as where it is properly applied in sufficient amount. With oil worth $1.25 per barrel, the cost of oiling a road is about $200 per mile. "Concentrates" is not informed of road sprinkling with oil for the purpose of laying the dust prior to 1894.

THE twenty rock specimens from Oregon have been determined as follows: No. 1, Quartz showing iridescent tarnish, due to iron and copper salts: 2, infusorial earth; 3, rhyolite tuff; 4, chalcopyrite with malachite, (copper carbonate) and iron oxide; 5, diorite with abundant small grains of magnetite; 6, talc veinlets in serpentine; 7, talc; 8, chromic iron; 9, decayed dike rock with cinnabar (mercury sulphide); 10, chrysoprase (color due to nickel) with millerite, (nickel arsenide) in fine needle-like crystals: 11, same as No. 10; 12, galena (lead sulphide); 13, serpentine; 14, silicified dike rock containing magnetite; 15, an intrusive rock (diabase) silicified; 16, similar to 15; 17, kaolin, iron oxide and sericite; 18, kaolin, iron oxide, talc scales, and possibly gold (all rocks of this appearance should be assayed on general principles); 19, decayed dike rock, probably diorite; quartz, chrysocolla and kaolin. (This may also contain gold.)

WHERE cutting out for a station at a shaft, sufficient head room must be made near the shaft for handling long timbers and removing same from skips to the level. It is also economy to cut the ore and waste bin under the level at the time of sinking, and not after the shaft has been continued below and timbered past the chute. The bin under the floor of the station should be divided by a strong partition, so that ore and waste may be kept separate. Where it is not expected to break much ore on a level, a temporary apron may be provided to chute rock from the car into the skip, and the ore bin below may be dispensed with. Where the vein has a flat dip—less than 20°—the ore bins should be provided in the same manner as where veins are steeper. It requires the removal of more ground, but it saves handling rock, and avoids the necessity of sending the cars to the surface which are used on the levels. This practice always necessitates more or less delay, both underground and on the surface.

IT is not uncommon to find several kinds of rock as a result of cooling of the same magma. A great difference in structure of these several varieties is particularly noticeable. This is due to the unequal periods of cooling. Those portions near the border of the molten mass cool more quickly, and are, consequently, finer in grain than the portion forming the central portion. Where injected magma is deep seated and a very long time in cooling; an exceptionally coarse crystallization usually results. This is a feature of that class of granitic dykes known as pegmatite, in which the individual minerals occur in the form of large crystals. Among these are black tourmalines, green apatites, large crystals or "books" of mica, from which the merchantable mica is obtained; large masses of feldspar and quartz, the latter sometimes of beautiful rose tint. The granitic intrusions of the Black Hills, South Dakota, are of this class, and many of them contain this stone in greater or less quantity.

THE curvature of the earth is about 8 inches per mile of horizontal distance, or accurately 0.667 foot. This increases as the square of the distance, thus the amount of curvature in 3 miles would be 9 times 8 inches, etc. This is lessened somewhat by the refractive power of the atmosphere, which is a variable factor increasing and diminishing with changing temperature, humidity and elevation above the sea. This refraction has a tendency to make distant objects appear to be higher than they really are. An average is placed at about one-seventh the curvature of the earth. At sea the summit of a mountain 5717 feet high would just be visible on the horizon at the distance of 100 miles. In running long tunnels engineers take the curvature of the earth into consideration. A horizontal line is not a level one, for a straight line cannot be level. Level means a line at right angles to a line drawn to the center of the earth (a plumb line) and this direction changes with every movement along the earth's surface.

SOME salts have a great affinity for water and absorb moisture from the atmosphere and become moist. This is known as deliquescence. It is exhibited in a marked degree by common salt. Some sulphide minerals also have this property. A sulphide of iron occurring in the Boomerang mine in San Bernardino county, Cal., where the climate is dry, upon being taken to the museum of the State Mining Bureau at San Francisco, Cal., where the air is more humid, in the course of a few months became covered with an efflorescence and gradually crumbled to powder. The water of crystallization is present to a greater or less extent in most minerals. It is usually driven off by heating the mineral to 212° F. Borax is a notable example of this. Alum is another. When minerals of this kind are heated they usually swell up and occupy more space than when in normal condition (intumescence) and then fuse down to a colorless glass. Borax is a useful flux in assaying, but only "borax glass," as the mineral is called that has had the water of crystallization expelled, can safely be employed, as the mineral while containing the water of crystallization would cause the contents of the crucible to overflow and destroy the value of the assay for commercial purposes.

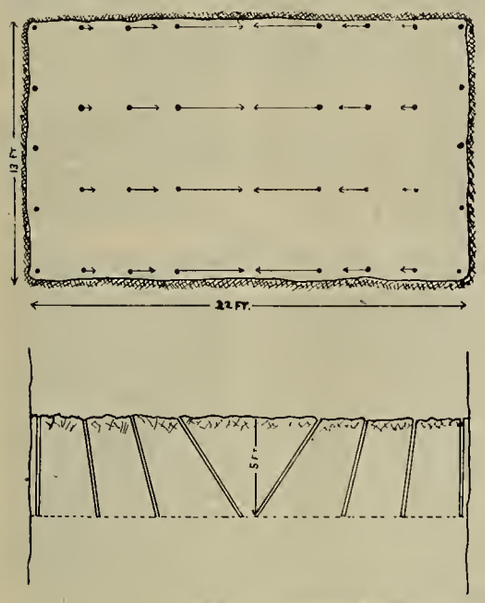
Some Features of Mining Operations in the Homestake Mine, Lead, South Dakota.

NUMBER II.

Written for the MINING AND SCIENTIFIC PRESS by
BRUCE C. YATES, E. M.*

The cost of a set of timbers in place for the Ellison shaft is:

Timber	$26 85
Framing timbers	10 00



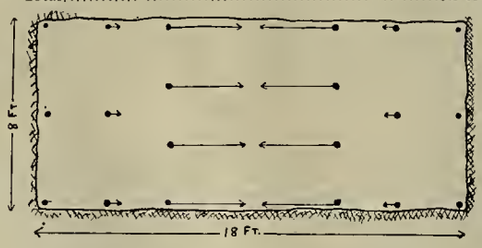


Fig. 4.—Diagram Showing Disposition of Holes for Blasting in Shaft.

including the placing of the timbers. The cost of labor per foot of shaft, assuming that the contractors made $4 per shift, which is the usual price paid to shaftmen, is as follows:

Eight miners at $4	$32 00
One timberman at $4	4 00
Two engineers at $4	8 00
Two landers at $3	6 00
One-sixth set timbers, lumber and framing	10 64
Total	$60 64

Four miners, one shift, at $4	16 00
One lander, one shift, at $3	3 00
One timberman, one shift, at $4	4 00
One engineer, one shift, at $4	4 00
Total	$63 85
Cost per foot	10 64

The average progress made is 1 foot in two shifts, or two machines are used for drilling, mounted on a horizontal bar. The bar has two decided advantages over the column, namely: the machine may be set up as soon as the blasting is finished and drilling for the next round goes on while the shovelers are removing the rock, and the sides of the drifts are carried much more evenly than with the column, which makes it

The Rand machine is used for drilling, mounted on a bar. The manner of placing is shown by Fig. 4, which gives horizontal and vertical section of a standard three-compartment shaft. Electric exploders are used to fire the blasts in all the shaft work, 40% dynamite being used, as in drifting.

The dimensions of the shafts, size and framing of the timber are illustrated by Figs. 5, 6 and 7. As all the shafts are vertical, no special features are introduced. Station sets are from 12 to 16 feet high. Two or three extra sets are put in on the stations, which serve as braces to the long sets of the shaft and support the roof of the station.

Formerly all station floors were covered with sheet iron. On all the new levels, however, the track rails are laid to the edge of the shaft and in line with the cage rails. Two tracks are laid up to the shaft, one to each hoisting compartment. A diamond crossover, located close to the shaft, permits the loaded cars to run onto either cage and the empties to be returned to the empty track. Fig. 8 shows the arrangement of the crossover, and by noting the position of the lever and spring points the manner of operation is easily understood. A third track passes around the shaft when the station is opened on both sides. The cages are made at the company's shop and are provided with the usual safety appliances. All new cages are made with the chair and operating lever on the cage, so that the cage tender always has control of the chairs. Double-decked cages are used at the Ellison shaft, which carry two cars on each deck. The Golden Prospect cage carries two cars on a single deck, and all other shafts have small, single decked cages. Skips have not been used in any shaft now belonging to the Homestake Co.

DRIFTING.—Three dimensions are used for "dead work" drifts, depending upon the use for which they are intended: prospect drifts 6x7 feet, single-track working drifts 7x8 feet, double-track working drifts 12x8 feet.

Prospect drifts are usually driven under contract, two men being employed on each shift. Each man is a party to the contract. The miners car their own rock, furnish powder, fuse, candles, shovels and picks, aud pay for the repairs on machines. The company furnishes machine and drills, lays all track and puts in air pipe as needed. The price paid is from $5 to $8 per running foot, depeuding on the character of the rock.

No timbering is required except in a few isolated cases, where a soft seam is encountered, necessitating standing a few tunnel sets.

In running the 7x8 single-track drifts, either one

easier to lay a straight track and allow ample room for a ditch on one side.

Mounting the machine on a bar instead of a column has only lately been tried in the Homestake mine, and the result has proven very satisfactory. Machine men say that it is easier to move the machine from one position to another, which fact is an advantage to the miner and will, in the end, materially advance the interest of the company.

The manner of placing the holes is illustrated by Fig. 9, which represents the face of a drift. The direction and inclination of the holes are shown by arrows, and the order of blasting the holes is indicated by numbers.

The following tabulated statement shows the cost of 5 feet of average 7x8-foot drift:

One miner, two shifts, drilling, at $3 50	$ 7 00
One helper, two shifts, drilling, at $3	6 00
One miner, one shift, blasting, at $3 50	3 50
One helper, one shift, blasting, at $3	3 00
One shoveler, two shifts, at $3	6 00
Explosives—Powder, caps and fuse	10 75
Blacksmith labor, repairs of machine, and machine shop labor	4 85
Total cost	$41 10
Cost per foot	8 23

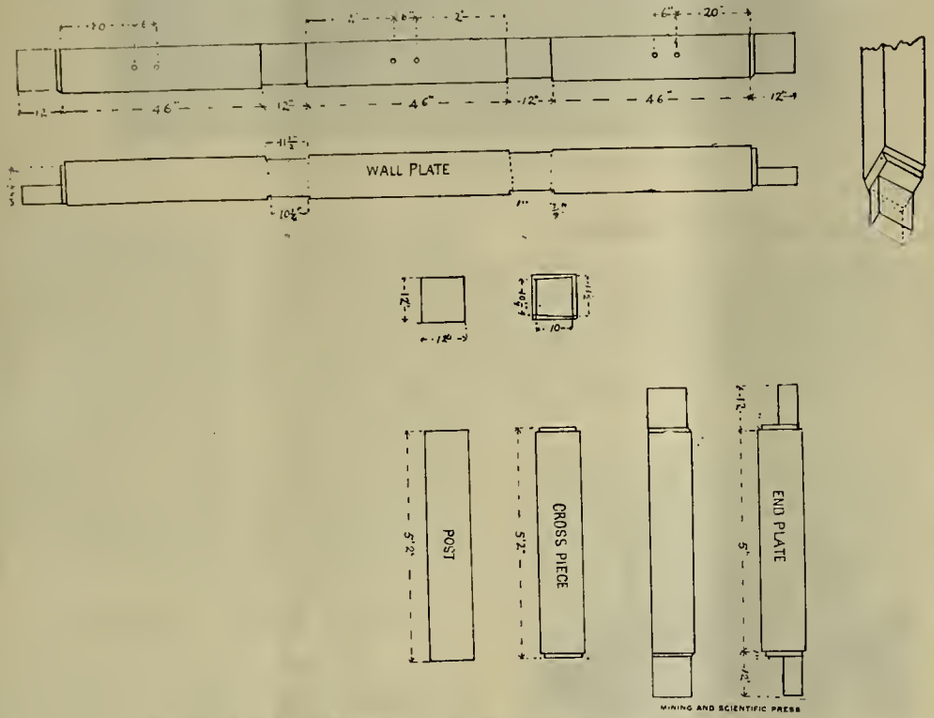

Fig. 5.—Members of Shaft Set, Three-Compartment Shaft, Homestake Mine.

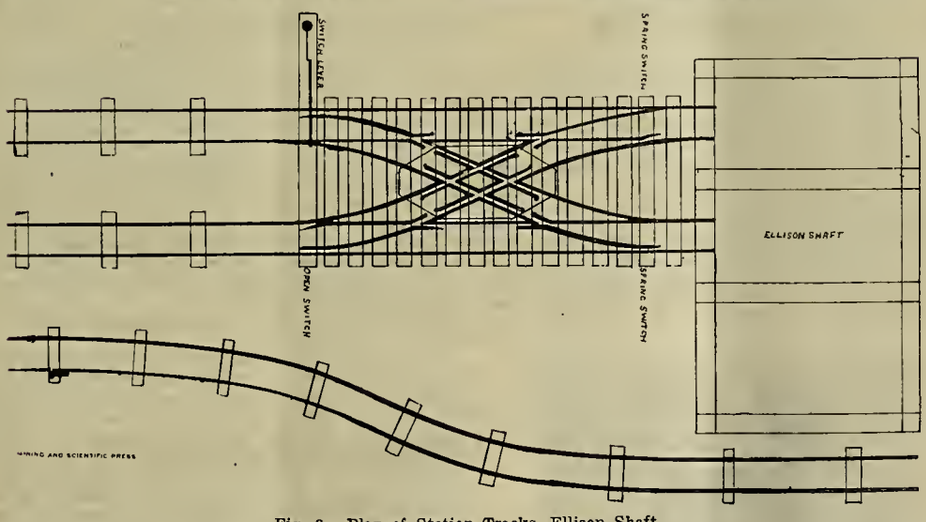

Fig. 8.—Plan of Station Tracks, Ellison Shaft.

The above cost statement does not include the cost of laying track or putting in air pipe. This was left out because track and air pipes are a part of the permanent improvements of the mine, and not all of this item should be charged against any particular drift. (TO BE CONTINUED.)

MINISTER A. M. BEAUPRE, of Bogota, Colombia, reports that Colombia has passed a new mining law, which is intended to develop the many gold, silver and platinum mines of that country. It provides that a tax of $10 be paid for each denunciation and $50 for the concession title, paper money, and a scheme of annual taxation for working the same. All mining machinery going there will be admitted free of duty. An effort was made to amend the law so that all mines, including iron, copper, zinc, sulphur, and precious stones, could likewise be denounced and acquired by individuals, but it was defeated.

A Code of Mine Regulations.

It is the desire of the management of mines everywhere to avert accident and disaster in the operation of the mines under their direction, but generally only ordinary methods are employed to promote these humane and business-like ideas, and simple rules are made for the purpose, governing the conduct of the men and the use of the company's property. The following "Notice to Employes," posted about the various mines and works of the Federal Mining and Smelting Company of Wallace, Idaho, is one of the most comprehensive codes of rules and regulations yet issued with the above-mentioned purposes in view, and it seems so complete and so suggestive that it is given space in full:

ALL EMPLOYES MUST READ THESE RULES CAREFULLY BEFORE GOING TO WORK.

1. The following rules must be strictly observed by all miners and other workmen employed by the above named company.

The object of those rules is to obtain the greatest possible safety for all employes. It is hoped that all, by using the utmost caution in the performance of their respective duties, will co-operate in securing the safety both of themselves and their fellow workmen.

GENERAL.

2. It is the duty of all employes to take sufficient time to make the examinations required by these rules, to guard against any dangers from accidents in the mine or its workings.
3. Each man must ascertain by careful examination thereof that the particular place in which he is employed is safe. If found to be in an unsafe condition from any cause whatever, measures must be taken to remove such danger at once and before proceeding to work, and if necessary the foreman or shift boss must be notified.
4. It is the duty of every employe to warn his fellow employes and boss of any danger which threatens or which may appear to threaten to cause injury to any person or the property of the company.
5. No smoking will be allowed while on duty or any time around the premises, except under ground during lunch time only.
6. All employes who cannot read must report same, or be reported to the foreman, shift boss or timekeeper, or any other employe, who will thereupon read these rules over to him, explaining the same thoroughly, and no man will be permitted to go to work without first reading and signing these rules in the office of the company at the mine in which he is to work.
7. Any machinery noticed to be defective must not be used until fully repaired by competent mechanics, and no one is permitted to assume the duties of a fellow workman in the running of any machinery not in his charge, unless authorized to do so by the foreman or master mechanic.

GENERAL MINING.

8. Throughout the mine, and especially in the stopes, there are many openings which must be carefully avoided. Some of these openings are in constant use, such as man-ways, timber-ways, chutes, etc. There are others not so constantly used which may be temporarily open. All employes are warned to observe these latter openings and to warn their fellow employes of the same and see that the same are covered, or to warn their boss to cover them when not in use. Workmen using any openings shall warn approaching employes of any existing danger.
9. Miners driving drifts, crosscuts or raises which are to connect with other workings must not blast when such drift, crosscut or raise is within 10 feet of such other working, before word has been sent to warn all employes to keep away from the vicinity where the connection is expected to be made.
10. It is the duty of all employes working in any raise, drift, crosscut or winze whenever a connection with other workings is made, to notify their shift boss, who shall write plainly on the bulletin board provided for that purpose, when such connection was made with other workings, so that the on-coming shift will be aware of any danger or dangerous place.
11. Drills, timber or other material must not be placed within 5 feet of any shaft opening or winze.
12. It is the duty of machine men to see that their machines, air drill hose and tools are removed a sufficient distance to escape injury from blasting.

EXPLOSIVES, MISSED HOLES, ETC.

13. Before blasting, employes must warn all persons within range of danger; and, after spitting fuse, guard all avenues of approach against persons coming unawares towards place being blasted. All employes while blasting must remain in a safe place within hearing distance, and count the number of shots heard, and carefully note the number of missed holes, if any. No employe shall, under any circumstances, approach a missed hole within thirty minutes after spitting the fuse. The fuse used burns not less than 1 foot in twenty-three seconds. No fuse less than 6 feet in length must be used.
14. Miners who have blasted on coming off shift must notify their shift boss and the on-coming shift if there have been any missed holes, and how many, so that they may have full knowledge of the matter. In such cases the shift boss coming off shift must write plainly on the bulletin board provided for that purpose, the place where the missed holes have been left and the number of missed holes; also fill in blanks furnished for keeping record of missed holes. It is the duty of the on-coming shift to find out if there are any missed holes or other danger where they are going to work.
15. When returning to any place after a blast or blasts have been fired, each employe upon entering such place must make a careful examination for any loose rock or other elements of danger by which he could be injured, and if any such be found he shall immediately make it safe, or, if unable to do so himself, report the same to the shift boss or foreman before proceeding to work. Employes must carefully examine the workings before setting up machines, for loose or scaling rock or any elements of danger, and all missed holes must be fired before drilling is commenced.
16. When blasting choked chutes warning must be given in both directions so that no one may come opposite or too near such chutes at time of firing.
17. All blasting of boulders in stopes must be done under the direct supervision of the shift boss and NOT otherwise.
18. All sticks or pieces of giant powder, fuse or caps, not used must be taken from drift or other place to place prepared in crosscuts, and not left around the mine. Lighted candles or torches, or any other naked light must not be taken into magazines or near capping benches or place prepared for powder in crosscuts or elsewhere, as these places are lighted by electric lights or other enclosed lights. The temperature of magazines or other place where powder is kept must not exceed 65° Fahrenheit. Thermometers are furnished to test temperatures. If any thermometer is broken the first employe discovering such breakage must immediately report it to the foreman. Smoking in or about any of the above places is strictly forbidden. Caps must not be carried to powder magazines.
19. Miners must not carry giant powder or caps in their pockets or boots. When using less than a stick of powder, the stick must be cut with a knife, and not broken without cutting. Picking giant powder out of a hole is strictly forbidden. No tamping of powder with steel or iron bars is al-

lowed. Capping benches must not be less than 50 feet from powder magazines.

RULES FOR OPERATING TUNNEL TRAINS AND TRAMMING ON LEVELS.

20. Tramming is constantly going on throughout the mines on the levels and tunnels and all persons must be constantly on the lookout for cars and trains.
21. No one shall get on or off tunnel trains while same are in motion.
22. Motormen must not run their trains at a greater speed than 6 miles per hour, and it is the duty of the motormen and all other employes on trains to see that switches are properly set and that no open switches are left in the direct route the train is taking. Switches of this company are of the general railroad pattern and must he kept closed so as to prevent accidents. If motors, cars, track, or other equipment is noticed to be defective, same must he reported to the foreman so that immediate steps can he taken to repair the same. In coupling cars the hand must not he used under any circumstances, unless the train is at a standstill.
23. Trains or cars passing a person or persons in tunnel must slow down and give such person or persons sufficient time to get off tracks.
24. Motormen must keep their motors clean and in good order. In handling passenger coaches the motor must always pull the coaches and never push the same, except when the coaches are empty.
25. Any employe riding on the electric locomotives does so at his own risk. No one is allowed to ride on the ore trains. This company does not furnish hand-cars for the use of its employes.

SHAFT AND HOISTING RULES.

26. Engineers in charge of hoisting engines at the change of shift and at meal times shall first send down the cage empty to ascertain that the shaft is clear and safe before lowering the men down in the shaft.
27. Not more than eight men at a time shall ride on each deck of the cage at the Standard mine, and not more than six men at a time on each deck at the Burke mine. Riding upon timher skip in any shaft, raise, winze or elsewhere is positively forbidden.
28. It shall he the duty of the mechanical department to daily inspect the hoisting ropes and engines to see that the same are in a safe condition and in proper repair, and if at any time the rope or any part of the machinery shall appear to be out of order, to have the same repaired before continuing with the hoisting.
29. Tools, steel, drills, timber and other material must not he lowered or hoisted except when placed inside cage or other conveyance and made safe by fastening. When men are hoisted the cage or other conveyance must commence to slow down within one hundred (100) feet of the sheaves. Men must not he lowered or hoisted at a speed greater than 6 miles per hour, and when the cage on which men are heing lowered approaches a station where chairs are in use the speed of the cage must he materially lessened.
30. No employe must leave the shaft at any station without first seeing that the har is properly placed in position, so as to prevent any one walking into the shaft opening.
31. Cage men must, immediately after the cage is hoisted, remove the chairs and see that everything is clear for the cage to pass.
32. No one shall pull the electric signals or bell rope hut the cagers, unless hy express permission of the foreman.

SPECIAL RULES FOR SHAFT SINKING.

33. Before spitting fuses the hlasting signal must he given to the engineer, and the fuse must not he spit until the engineer replies by hoisting the cage hucket a few feet and lowering it again. The engineer after answering the signal must remain ready to instantly hoist the men from danger.
34. For shaft firing the shortest fuse must be at least 9 feet in length.

SPECIAL WARNING AS TO ELECTRIC WIRES AND OTHER ELECTRICAL APPARATUS.

35. All employes are warned to carefully avoid coming in contact with any electric wires or other electrical apparatus, and are also warned not to touch them with any metal which is held in their hands, as all of the wires carry high voltages and are dangerous to touch.

By order of The Federal Mining & Smelting Co.

I, ..., having applied to the Federal Mining & Smelting Co. for work in its mines, do warrant that I have had experience in such work; that I know the duties which will be required of me and the nature of the places in which I will he required to work; that I am fully acquainted with the hazards of mining work and the nature of the places in which such work is carried on, and voluntarily assume the same; that I have received a copy of the foregoing rules, which I have read (which have heen carefully read to me), and which I thoroughly understand and agree to comply with.

A Card.

TO THE EDITOR:—There has come to my hand a circular prospectus of the Crowu King Mines Co., iu which my name is used without authority. I do not consent to the use of my name thereiu, nor do I vouch for any of the figures or statements contained in said prospectus. SAMUEL W. OSGOOD.

Chicago, Ill., Feb. 8.

Quartette Mill, Searchlight, Nevada. (See Front Page.)

Laboratory Ore Crusher.

Herewith is illustrated the Case laboratory ore crusher, regarding which the Denver Fire Clay Company of Denver, Colo., say that patents were issued W. W. Case of Denver, Colo., some months ago thereon, but before placing it on the market they wished to make a thorough test, that it is designed to supersede the Bosworth crusher, and that while it is, in all respects equal, to the Bosworth in poiuts of

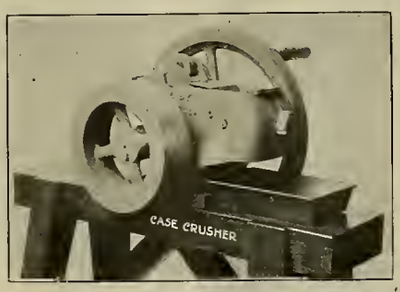

Fig. 1.—Laboratory Ore Crusher.

durability, strength of parts, capacity, adjustment and simplicity of cleauing device, it is considered superior. It is made for both hand and power. The illustrations show the power machine, which is equipped with a 9-inch belt pulley, 2¾-inch face. The manufacturers recommend 450 to 500 revolutions as best for all round laboratory work.

For several years the demand for power-driven crushers has increased. At present it is estimated that 75% to 80% of the sales are for power crushers, which, if properly constructed to stand the above speed, have a capacity ten times that of the hand crusher. Fig. 1 shows the crusher ready for use. Fig. 2 shows it opened to clean. To open is required

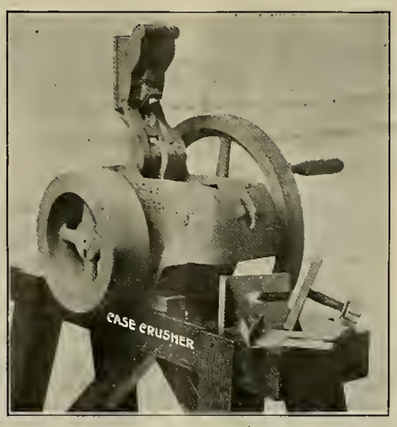

Fig. 2.—Laboratory Ore Crusher.

two or three turus of the hand wheel at the frout and of frame, which loosens the front jaw plate aud edjustment shims, the top being then lifted out. The rear jaw plate can then be raised and swung back, as shown in Fig. 2. This cleaning device is quickly operated and does uot weaken the crusher frame.

The adjustment for fine or coarse crushing is made by use of sheet steel shims, which are inserted between the front jaw plate aud the frame, the shims having a slot, as shown in Fig. 2, allowing it to drop astride the bolt connecting the jaw plate with hand wheel. This adjustment affords a variation of from one-quarter to thirty mesh, and does not alter the relative position of the front and back jaw plates. The motion of the movable jaw is such as to give it good feed and still not cake on soft material. The rear jaw plate is held by one taper head bolt in the center, so that wheu the lower end becomes worn it can be reversed. The frout plate is also reversible.

The capacity of the crusher, driven by 1 H. P., is stated to be from 100 to 200 pounds per hour. The jaw opening, 2½ inches by 3 iuches; all parts duplicated; weight, 135 pounds.

Hydraulic Mining in Cariboo, B. C.

The anuual report of operations of the Con. Cariboo Hydraulic Mining Co., submitted by Manager J. B. Hobson, E. M., to the company at a recent meeting held in Toronto, Canada, shows some interesting details of the large operations in progress in Cariboo. In his report Mr. Hobson says in part:

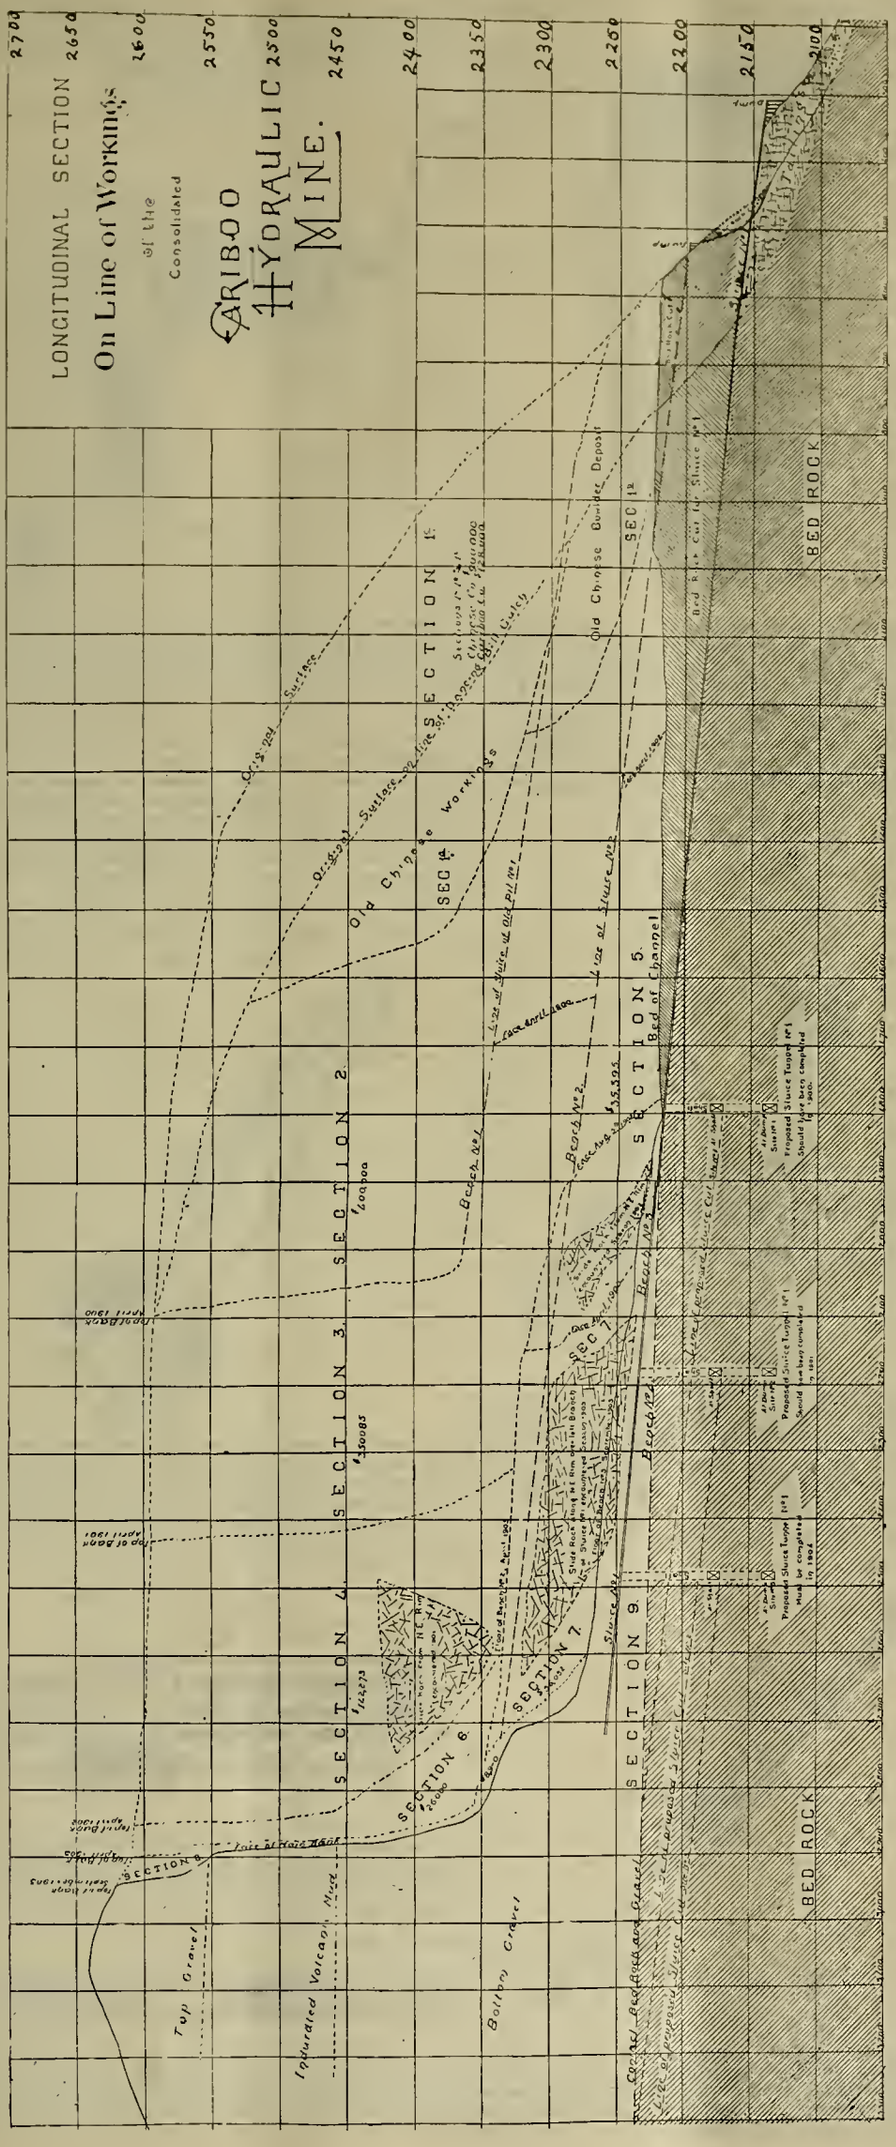
The past season turned out a disappointing one, for the reason that the 26 inches of well settled snow that laid ou the watershed at the end of March went off maiuly by evaporation under the influence of the cold frosty weather, accompauied by the northerly winds that prevailed during the months of April and May, affordiug barely sufficient water to operate the miues fifty-three days and seven hours, with a quantity of water varying from 2000 to 2500 miner's inches, being twelve days and eight hours short of the washing time reported for season 1901, and 118 days and six hours short of the washing season reported for season of 1900.

The season's mining operations were divided iuto two runs as follows:

Washing was commenced on the third bench in pit No. 1 on the 21st day of April, was continued for a period of forty-five days and seven hours, ending July 15th. During the progress of the run 111,083 miner's inches of water were used to wash out a slide of indurated volcanic mud, containing about 68,000 cubic yards, that came into the excavation from the northwest rim on the big bend of the chaunel north of Dancing Bill gulch, and 248,000 cubic yards of the rocky deposits of the the third bench, making a total of 316,000 cubic yards for the run, from which was recovered $2115\frac{85}{100}$ ounces of gold, valued at $36,032.94, an average yield of $14\frac{53}{100}$ cents per cubic yard for the 248,000 cubic yards of gravel and slide rock washed from the third bench, which was carried up to the face of the main bank.

About half the washing time was applied to the excavation of the rocky cuts required to accommodate the right and left brauches of sluice No. 1, which were advanced 740 feet on the right and 704 feet on the left side of the excavatiou.

The second run, commeuced on the 21st day of July, included a period of eight days, ending with the exhaustion of the water supply on the 21st day of August. During the progress of the run 16,000 miner's inches were used to wash out about 12,000 cubic yards of slide rock that came iuto the excavatiou from the southwest rim, and 44,000 cubic yards of gravel from the main bank, making a total of 56,000 cubic yards for the run, from which was recovered



523 24/100 ounces of gold, valued at $8910.76, an average yield of 20 24/100 cents per cubic yard for the 44,000 cubic yards of gravel washed from the main bank. The right hand branch of sluice No. 1 was advanced 45 feet, making the advancement of sluices amount to a total of 1489 feet for the season.

The grade of the deposits of the third bench increased gradually as the workings were carried up channel towards the main bank, but the immense deposits of slide rock, found lying next to the northeast rim, on line of left branch of sluice No. 1, replaced a large area of the pay strata, and caused a material reduction in the average yield of the ground worked. The removal of this immense deposit of broken, angular rock retarded the progress of the work, and added materially to the cost of mining, and the excavation of cuts required for the advancement of left branch of sluice No. 1.

The results of the second run is encouraging, and indicates a continuation of the high-grade deposits that gave satisfactory results prior to the season of 1901, where enormous deposits of slide rock from the rims were found replacing large areas of the high-grade strata composing the main body of the fill found between the rims of the ancient river.

The light gold output may be laid to the short water supply, the working time lost in removing large masses of slide rock, encountered while carrying the workings up stream, and excavating cuts for advancement of sluice branches.

SUMMARY OF THE SEASON'S MINING OPERATIONS.

Quantity of gravel, clay and rock washed—	
Gravel from third bench, cubic yards	248,000
Gravel from main bank, cubic yards	44,000
Slides from rims of old workings and indurated volcanic mud, cubic yards	68,000
Bedrock slide, cubic yards	12,000
Total quantity washed, cubic yards	372,000
Average duty of water per miner's inch, cubic yards	2 92
Gold product for season, Troy ounces	2,639 09
Value of gold	$44,943.70
Total time occupied in washing in pit No. 1, 53 days, 7 hours.	
Total quantity of water used, miner's inches	127,083

CONDITION OF THE MINE.—To better illustrate the subject, I have prepared the accompanying longitudinal section on line of workings.

By reference to the longitudinal section you will note that all the ground in the third bench, including sections Nos. 5 and 7, has been worked out up to the face of the main bank, leaving the shallow bench of ground between sluice No. 1 and bedrock as bench No. 4, extending from the point where sluice No 1 goes above bedrock at A, about 1100 feet to the face of the main bank.

Sections 1 a, 1 b and a portion of 1c were worked out by the Chinese, who reported a gold recovery of $900,000. The Cariboo hydraulic mining companies worked out the remainder of sections 1 a, 1 b and 1 c and recovered therefrom $128,000. The Cariboo Hydraulic Mining Co. worked section No. 2 and recovered therefrom gold valued at $400,000. The Cousolidated Cariboo Hydraulic Mining Co. worked section No. 3 during season of 1900 and recovered therefrom $350,085.77. Section No. 4 was worked out in 1901 and produced $142,273.41. Sections Nos. 5 and 6 were worked out during season of 1902. Section No. 5 produced $35,395.19, and section No. 6 produced $26,000, a total of $61,395.19. Sections Nos. 7 and 8 were washed during season of 1903. Section No. 7 produced $36,032.94, and section No. 8 produced $8,910.76—a total of $44,943.70—making the total gold product for the 2370 feet of channel worked amount to $2,026,698.07.

The bedrock cut B and sluice tunnel No. 1, at site No. 1, should have been completed during season of 1900, so that all the ground included in sections Nos. 4, 5, 6, 7 and 8 and the fourth bench, included in section No. 6, could have been washed through sluice, cut and tunnel at reduced cost for mining and sluice maintenance, but the delay in the delivery of the power drill plant and electric appliances until late in 1901 made it impossible to complete either cut or tunnel as expected.

The sluice tunnel must be driven from site No. 2 or No. 3 during the season of 1904, to afford outlet to the dumps for the ground worked during season of 1905.

Since the sluice cut has been lowered and the branches of sluice section No. 1 have been carried up to the main bank—and the working face includes a greater depth of high-grade gravel than has been exposed for washing since the opening of the property—the mine is in better condition for continuous and profitable operation than it was at the opening of the season of 1900, when $200,000 was netted out of a product of $350,085.77.

(TO BE CONTINUED.)

THE upward blows of a cam upon the tappet of the stamp mill have a tendency to drive the tappet upward, and this tendency is not overcome nor equalized by the momentum of the falling tappet when the mill is in motion. As a consequence, tappets if not firmly keyed have a tendency to move upward on the stamp stem. When the cam shaft is making fifty revolutions per minute (100 drops of the stamp) the cam strikes the tappet moving at a speed (at the point of contact) of about 5 feet per second. The force of the blow is proportional to the weight of the cam when moving at a stated velocity.

Mining and Metallurgical Patents.

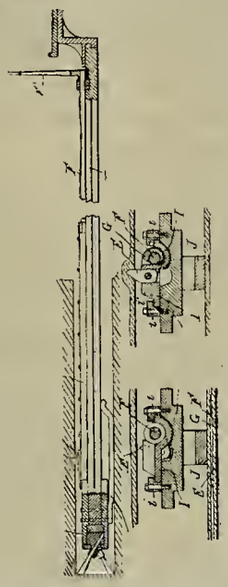
PATENTS ISSUED FEBRUARY 9, 1904.

Specially Reported and Illustrated for the MINING AND SCIENTIFIC PRESS.

WELL DRILL JAR.—No. 751,199; G. B. Patton, Williamstown, W. Va.

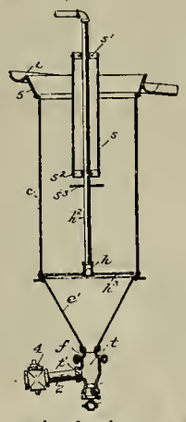
A device of kind described comprising shell, bushing secured in one end of shell, screw plug having inner tempered end fitting in opposite end of shell, plunger working in shell through bushing, and removable cap secured to inner end of plunger.

MINING MACHINE.—No. 751,478; H. B. Dierdorff, Columbus, Ohio.



In mining machine, combination, of bed, carriage, laterally acting cutters on carriage, holding device rigidly connected with carriage laterally and adapted to be moved toward and from carriage, and means for moving holder device at will into and out of engagement with coal.

PNEUMATIC HYDRAULIC SEPARATOR.—No. 751,645; F. W. Hopkins, Denver, Colo.

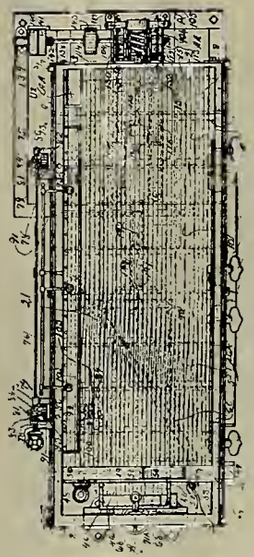


In combination casing having upper end and lower outlets, means for introducing air into casing extending throughout entire cross sectional area of casing to diffuse air gently throughout entire mass of material, casing being unobstructed for passage of material upwardly and downwardly according to weight, inlet for crushed material at point below surface of liquid in casing and deflector or spreader extending across inlet to spread material issuing therefrom and to prevent escape of air therethrough, air-introducing means being located at distance below deflector with liquid space intervening.

PROCESS OF TREATING COPPER ORES.—No. 751,648; N. V. Hybinette, Plainfield, N. J.

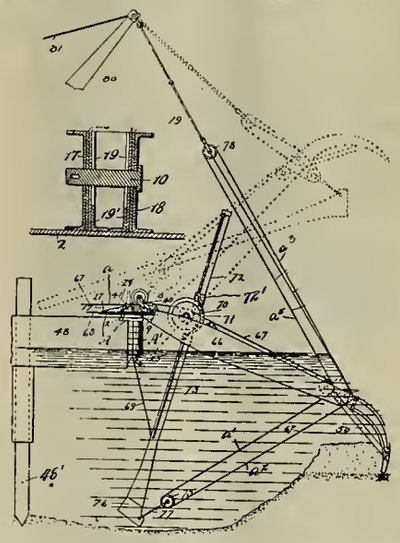
Method of treating ores of copper and similar metals by subjecting ore in state of coarse division to oxidizing roasting and converting metallic compounds thereby into more or less soluble condition, then roasting it with reducing agent, thus rendering compound insoluble, treating mixture with water and separating finely divided valuable material from coarser gangue.

ORE CONCENTRATOR.—No. 751,971; H. S. Bailey and W. E. Wild, Denver, Colo.



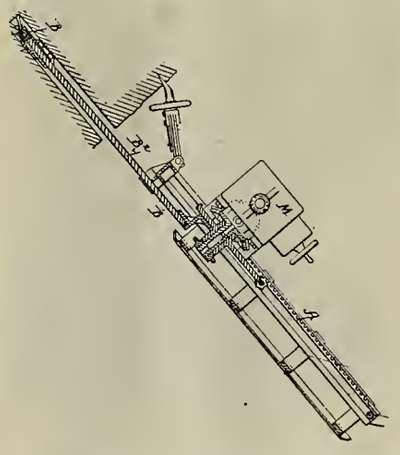
In ore concentrator, reciprocating table containing plurality of ore pulp receiving recesses of predetermined length, width and depth; plurality of ridges or dams extending across ore pulp receiving recesses, plurality of concentrates washing and classifying portions below dams, means for feeding ore pulp into and across recesses, and means for flowing supply of clear water over concentrates below ridges or dams, and means for tilting and for reciprocating table.

DREDGE.—No. 751,937; R. R. Osgood, Troy, N. Y.



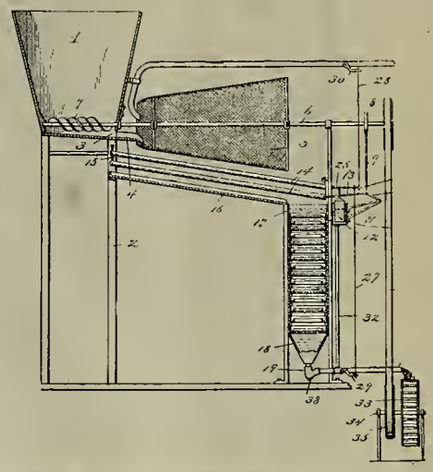
In dredge or excavator, hinged boom, dipper sustained thereon upon handle arranged to travel back and forth within bearings on boom, hoisting chain connected with dipper below boom and extending above boom, for operation, and a bank-engaging anchor upon extremity of boom.

MINING MACHINE.—No. 751,919; J. A. Jeffrey, Columbus, Ohio.



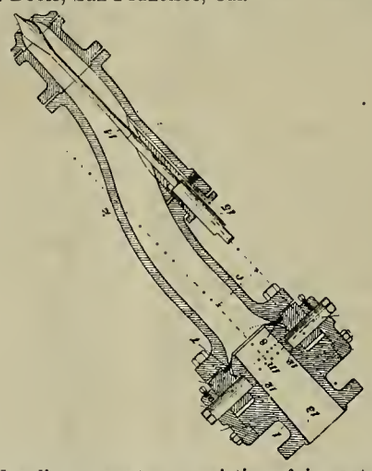
In mining machine, combination of cutter chain, carriage supporting chain, bed for supporting and guiding carriage, power devices for actuating cutter chain and moving carriage, and holding device for carriage, consisting of endless chain supported on carriage and adapted to engage with one of horizontal walls of kerf, and to have its active portion moved backward on lines parallel to path of carriage while moving bodily forward therewith.

AMALGAMATOR.—No. 751,911; R. P. Hall, Gem, Idaho.



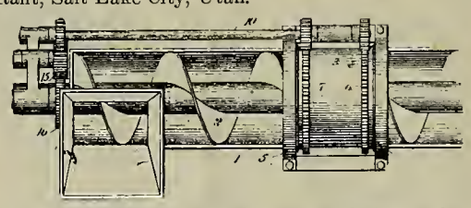
In amalgamator, combination with hopper, having shaft journaled therein and extending therefrom; of feed mechanism within hopper and upon shaft, revoluble screen upon shaft adapted to receive material from hopper, reciprocating screens thereunder, inclined board below screens, receptacle adapted to receive material from board, series of trays within receptacle and arranged one above other, trays having apertures in bottom thereof arranged out of alignment, trap communicating with bottom of receptacle, outlet pipe extending from trap, float, valve within outlet pipe, pipe for supplying water to screens and receptacle, valve therein, mechanism connecting valves and float, and means for rotating shaft.

NOZZLE FOR IMPACT WATER WHEELS.—No. 751,722; W. A. Doble, San Francisco, Cal.



Hydraulic apparatus, consisting of impact wheel with buckets, nozzle pipe of sinuous or double curved form for directing stream of water upon buckets of wheel, means for varying amount of water discharged from nozzle and supply pipe, to which nozzle pipe is pivoted on axis in plane of its sinuosity, plane and axis being parallel to axis of impact wheel.

ORE SAMPLING MACHINE.—No. 751,340; W. L. Raht, Salt Lake City, Utah.



In ore sampling machine, rotary chute member having opening between ends, and means for causiug discharge of material through opening at intervals.

WELL PUMPING APPARATUS.—No. 751,049; B. L. Brinton, Bradford, Pa.

In well pumping apparatus, the combination of well tubing, fixed workiug barrel at bottom thercof, removable working barrel having same internal diameter as fixed working barrel and external diameter less than iuternal diameter of tubing.

The Geology and Copper Deposits of Bisbee, Arizona.*

NUMBER III.

Written by F. L. RANSOME.

MINERALOGICAL CHARACTER OF THE ORES. — The ores worked by the Copper Queen Cousolidated Mining Co. up to 1893 were oxidized ores, consisting chiefly of malachite, azurite, cuprite and native copper. In the upper levels the malachite and azurite occurred as beautiful incrustations and stalactites lining caves in the limestones. These "cave ores" have been exhausted, and although oxidized ore is still abundant, it occurs generally as soft earthy masses, often containing cuprite and native copper, and usually associated with large amouuts of limonite and kaolin. Native copper and crystalline cuprite are still abundant in the recently opened workings of the Calumet & Arizona mine.

The original sulphide ores, from which the oxidized ores have been derived, consist of pyrite containing variable amounts of chalcopyrite and sometimes a little sphalerite. These pyritic ores are sometimes directly in contact with oxidized ores, but it is not uncommon to find masses of chalcocite between the two. The mineral, familiarly knowu as "copper glance," or "glance," is the most important sulphide occurring in the Bisbee quadraugle, since nearly all of the bodies of workable sulphide ore owe their value to its presence. So far as observed, it occurs only in massive form, distinct crystals being nowhere seen. It is sometimes firm and compact in texture, but is often rather soft and occasionally has almost a sooty character.

The chalcocite occurs at various depths, but uowhere far from ore showing at least partial oxidation. Its most characteristic place of occurreuce is in the irregular zones of rich sulphide ore that usually intervene between masses of lean pyrite and oxidized ores containing cuprite, native copper and carbonates. The ore of these zones often consists of soft crumbling pyrite, which is intimately associated with dull, crypto-crystalline chalcocite in the form of a thin envelope about the pyrite grains. The greatest depth at which chalcocite has been observed is 1050 feet, in the Calumet & Arizona mine. Bornite has been reported from some of the ore bodies, but arsenical or antimonial compounds of copper are absent, so far as known. The copper bearing minerals of the oxidized ores include malachite, azurite, chrysocolla, melanochalcite, aurichalcite, brochantite cuprite, tenorite and footeite.

Of the various gangue minerals associated with ores, calcite, in its role of principal constituent of the limestouc in which the important ore bodies occur, is the most abundant. It is seldom, however, that the mineral forms so large a part of the altered limestone in the immediate vicinity of the ore as it does of the unchanged rock in which mineralization has not been active. It has largely been replaced in the process of mineralization by pyrite, amphibole, pyroxene, garnet, chlorite, quartz, vesuvianite and other minerals. The resulting rock is usually of more compact texture than the unaltered limestone and is slightly g eenish in tint. The metamorphic silicates are, as a rule, recognizable only uuder the microscope, and the contact metamorphism is therefore very inconspicuous as compared with the altered limestones of the Cananea district to the south.

GENESIS OF THE ORE DEPOSITS. — Two general processes have operated to form the ores now exploited. These are (1) metasomatic alteration, including pyritic mineralization, and (2) oxidation and its atteudant phenomena of transportation and enrichment. Concerning the precise boundary betweeu these two general activities some difference of opinion is possible; but as regards the essential share of each in the genesis of the ores there can be uo question. There are few known ore bodies in the Bisbee quadrangle which do not demonstrably owe their value to the co-operation of both processes. This was also the conclusion reached by Emmons from the descriptions of Douglas and from a brief visit to the Copper Queen mine. The existence of workable masses of ore that have resulted wholly from the primary metasomatic mineralization, while not denied, is still as far from proof as when Dr. Douglas published his account of the Copper Queen mine four years ago.

As shown in thosc underground workings which are below the intermediate zone penetrated by oxidizing reagents, the sulphide minerals ascribable to the early period of metasomatic alteration are common pyrite, and perhaps also a little chalcopyrite and sphalerite. The occurrence of some cerussite in the limestones suggests that galena may also occur, although this mineral has not been seen. Associated with these sulphides are amphibole (tremolite), pyroxene (diopside), garuet (grossularite), vesuvianite, quartz and chlorite, in the limestones; quartz, sericite, chlorite, perhaps kaolin, and a little epidote in the granite porphyry; and quartz and sericite in the Pinal schist.

The metamorphic minerals are not distributed uniformly through the limestone, but are arranged iu zones about the porphyry stock of Sacramento Hill. Nearest the porphyry the former limestone is now a fine grained aggregate consisting chiefly of quartz and calcite. The width of this siliceous zone may be roughly estimated at about 200 feet. It is probably very irregular and is not sharply defined at its outer border. Although heavily impregnated with pyrite, it has not proved such favorable ground for ore as the next zone to be described.

Eucircling the siliceous zone are the palc green altered limestones in which pyrite, tremolite, diopside, grossularite and probably vesuvianite are the characteristic minerals. In this zone quartz is comparatively rare. Calcite, however, is abundant, and may make up half or more of the altered limestone. At its inner edge, this zone grades somewhat indefinitely into the siliceous zone. About its circumference it passes by obscure gradations into the unmetamorphosed limestones of the regiou. The rock of this zoue of metamorphic silicates is softer thau that of the inner siliceous zone. It is frequently traversed by little irregular surfaces of shearing, so that the rock tends to break along many curved surfaces into many small fragments. Thc width of this zonc cannot be stated with precisiou, on account of the indefiuite character of its boundaries, but it may be very roughly estimated at about 1000 feet. The zone is not, however, limited in plan to a simple concentric band about the porphyry, but exteuds for a considerable distance to the uorthwest, alongside the Dividend fault.

The town of Bisbee lies on the fault line. Thc hills northeast of the town are composed of pre-Cambrian schists. Those just south of it are upper Carboniferous limestone, with lower Carboniferous, Devonian and Cambrian beds coming successively to the surface along the fault to the northwest.

A little less than half a mile southeast of the center of town, the fault encounters a mass of altered granite-porphyry and as a simple fracture disappears. This porphyry, which forms Sacramento Hill, a local landmark, is a very irregular stock about a mile in diameter. It has invaded the pre-Cambrian schists on the northeast, and the upper Carboniferous (probably also the deeper-lying older Paleozoic beds) on the southwest. The available evidence indicates that the intrusion of this porphyry took place after the dislocation of the invaded rocks by the great fault. The latter probably continues to the southeast of the porphyry mass, but it is concealed in this direction by the younger Cretaceous beds. The Paleozoic beds forming the faulted syncline are not merely flexed, but are cut by many faults, some of them of considerable throw. These faults are, as far as seen, of the normal type.

The ore occurs very irregularly as large masses within the limestone. The horizontal extent of these bodies is usually much greater than the vertical. They are rudely tabular in form and lie generally parallel to the bedding planes of the limestone. As a rule, the important ore bodies have been found within a distance of 1000 feet of the main porphyry mass or of the great fault fissure just northwest of the porphyry. In the Czar workings of the Copper Queen mine, partly under the town of Bisbee, ore bodies have been worked from the surface down to a depth of about 400 feet, but toward the southeast the bulk of the ore occurs at increasing depths. In the Calumet & Arizona mine, about 3500 feet to the south of the Czar, no large ore bodies were encountered until the shaft had penetrated about 800 feet below the level at which the first ore body was discovered on the Copper Queen claim. The ore thus occurs at increasing depths toward the center of the local synclinal basin.

With thc exceptiou of the extreme western part of the Copper Queen mine, all of the productive and important workings in the vicinity of Bisbee are in the Carboniferous limestones. It is probable that the greater part of the ore bodies occur in the granular limestones of the lower Carboniferous, but the distinction between upper and lower Carboniferous beds can rarely be satisfactorily made underground. Some important ore bodies certainly occur in the lower part of the upper Carboniferous. On the other hand, no ore bodies of consequence have yet been found in the deeper-lying Devonian and Cambrian limestones. In the Copper Queen mine local usage has distinguished an "upper lime" and a "lower lime." As far as could be seen, however, this distinction is largely imaginary and is based on no constant lithological or structural features. Thc "lower lime" appears to be any limestone lying underneath the known ore bodies. It is in the main lower Carboniferous, and the ore-bearing possibility of the underlying and Devonian and Cambrian beds are yet to be ascertained by deeper prospecting.

Although the ore masses in general are what are usually termed "flat" ore bodies, dipping gently with the enclosing beds, they are related to other structures as well as to bedding planes. Ore is usually found in large masses along the contact of the limestones with the main porphyry mass. This contact, however, has not been thoroughly explored, and much of the ore aloug it consists largely of low-grade, partly oxidized pyrite. Dikes and sills of porphyry occur in the limestones at various distances from the main intrusive mass, and these are almost invariably associated with ore in the adjacent limestone. 'In some cases large ore bodies followed for a long distance in the general plane of the bedding have been known to turn dowu almost vertically alongside a porphyry dike. Fissures in the limestone have also uudoubtedly influenced the distribution of the ore.

While the main porphyry mass of Sacramento Hill is often heavily impregnated with pyrite, it has not been shown to contain workable ore bodies. It is certain, moreover, that many of the porphyry dikes encountered in the workings of the Copper Queen mines show little mineralizatiou even when in contact with ore.

(TO BE CONTINUED.)

* Abstract Trans. Amer. Inst. Min. Eng.

The Simplon Tunnel.

One of the greatest engineering projects of the day is the Simplou Tunnel, now approaching completion.

The total length of the tunnel will be 12.25 miles, of which distauce 6.25 miles have been penetrated on the north or Brigue side, 4.25 miles on the south or Italian side, leaving 1.75 mile still to be executed. Owing to the great height of the mountain above the tunnel—some 6000 feet—the pressure is great, and the temperature of the rocks and springs of water correspondingly high. The greatest heat encountered is 133° F., but it is now falling as the tunnel progresses southward, and at the present time is 126° F. Were this water to be allowed to fall on the workmen, injury would result. But thc simple expedieut is adopted of diluting it with cold water from the hydraulic mains, thus reducing its temperature to 70° F.

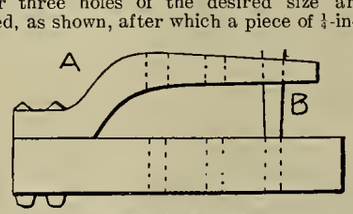
To cool the air in which the men are working, a large volume of fresh air, cooled by high-pressure water spray to 25° F. below the tunnel temperature, is sent right up to the working face. This point in other tunnels is generally foul and oppressive, but in the case of the Simplou is cool and fresh; and it is largely due to these precautions that no sickness exists among the men. The use of the drill suppresses all dust, and there has not been a single case of miners' phthisis, although some 3000 men have been at work for five years.

The advance galleries from Brigue have now passed both the summit of the tunnel and the frontier line between Switzerland and Italy; they are now on the descending gradient to meet the workmen coming up the corresponding ascending gradient from the south end of the tunnel. The aggregate monthly progress of the northerly and southerly ends of the advance galleries approximates a quarter of a mile. It is anticipated that, if no further or greater difficulties present themselves, a junction will be effected this year.

The volume of water flowing out of the south end of the tunnel is over 15,000 gallous per minute, and furnishes motive power to work the refrigerating apparatus and to compress the air by which the drills are operated. The tunnel when completed will be the longest in the world—14 miles. The cost will be $13,510,000.

A Guide for Punching.

The accompanying sketch shows an article of probable value in cases where nothing better can be procured. To make this punch guide, take a bar of steel 5 inches long, ⅝ to ¾ inch thick, and 1 inch wide. Two or three holes of the desired size are then punched, as shown, after which a piece of ¼-inch steel



A Guide for Punching.

is punched with the same number of holes in the same position, but somewhat larger, so as to hold the punch. The sccond piece is then fastened to the first by means of two rivets, and the tool is completed. A represents the spring, B the punch. The use to which this tool may be applied is punching holes in ⅜-inch boiler steel. If the end of the punch is carefully tempered one can thus punch several thousand holes. One can have several different sizes of holes and punches. If the points of the punches are kept in order, punching will not damage or split the plate. This device would ofteu save considerable time in drilling holes.

Rare Minerals in Oklahoma.

Although out of seventy-one specimens sent from the Wichita mountains of Oklahoma, only two contained a trace of silver and none of them a trace of gold, still there have been discovered other minerals which may prove of great value. In one of the samples which were sent to the United States Geological Survey laboratory the discovery was made of the mineral called columbite. It is not knowu that columbite has auy specific value of its own, but its presence is always significant, for it is known to

have a fondness for the society of certain minerals that contain rare and valuable earths. Among these is samarskite, the source of thorium, which is in demand for use in the manufacture of mantles for Welsbach lights. Pitchblende, another of these minerals, is the principal source of radium.

H. F. Bain of the United States Geological Survey made a reconnoissance of the Wichita mountains last fall, with the purpose of studying the reported occurrence of ores of copper, lead and precious metals. The samples collected were assayed by E. T. Allen, chemical geologist of the Survey. Among other minerals Mr. Bain found molybdenite.

Methods of Mining in the Vermilion Iron District of Minnesota.

Written for the MINING AND SCIENTIFIC PRESS by KIRBY THOMAS.

For more than a generation the copper and iron mines of the Lake Superior district have been considered models for operation on an extensive scale by mining men from all parts of the world. The great depth of these ore deposits and the comparatively wide and regular ore bodies have permitted developments to be carried on in accordance with carefully

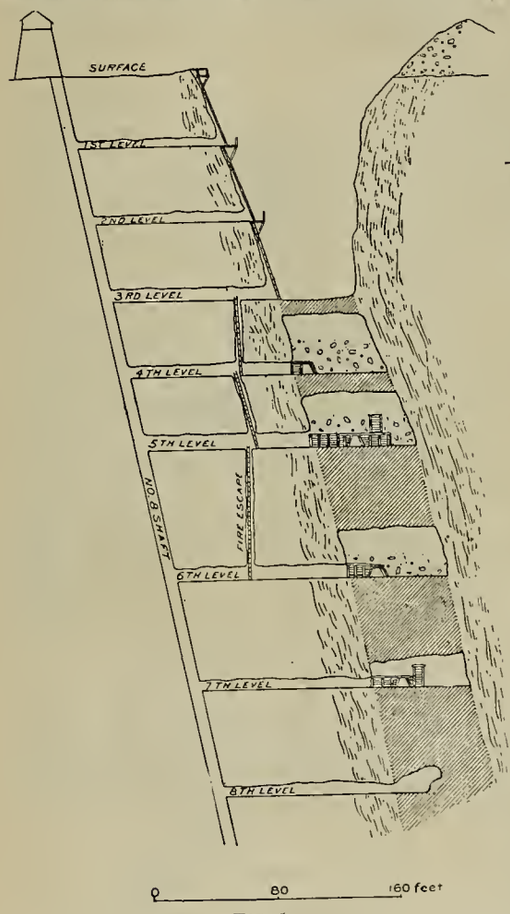


FIG. 1.

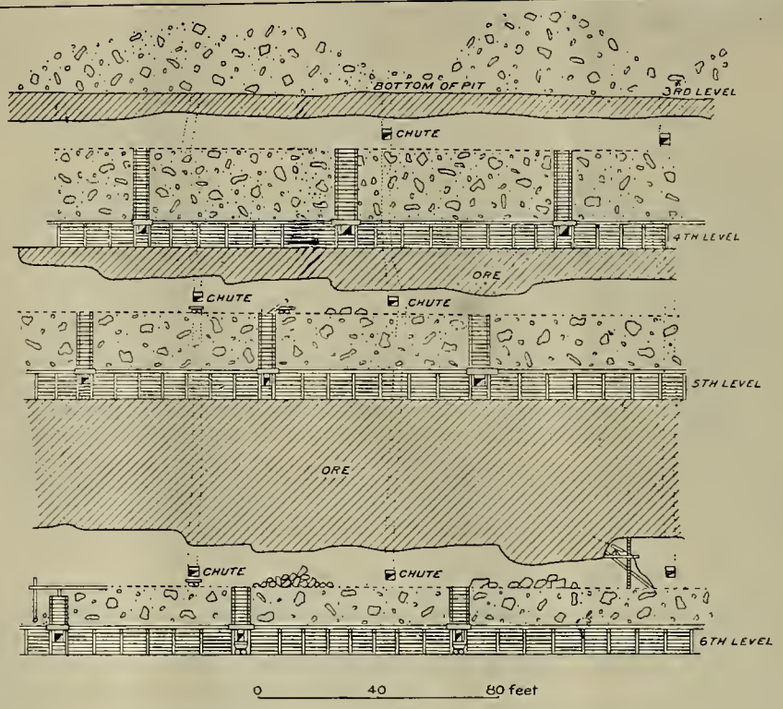

FIG. 2.

planned systems, and the extensive scale on which the mines have been operated has justified the best technical skill and the most effective of mechanical appliances. The iron mines at Tower and Ely, in the Vermilion district, in northeastern Minnesota, although only opened in 1884, are excellent examples of the best art in mining, and have long been looked upon as models by mining engineers and practical miners.

These mines have all been developed by the Minnesota Iron Co., now a part of the United States Steel Corporation, and from the start have had ample funds for carrying on the work in regard to the ultimate best results. The ore mined is hematite of bessemer grade. The output for 1903 was 1,676,744 tons for the mines at Tower and those at Ely. The total output to date exceeds 21,000,000 tons.

The ore is shipped by rail to Two Harbors, on Lake Superior, a distance of 72 miles from Tower and from Ely of 90 miles. Here it is automatically dumped into bins, from which it is loaded by gravity into large lake steamers for Lake Erie points.

A very excellent description of the methods of mining in the miues at Tower and in the Chandler mine of the Ely group is given in the recently issued monograph of the United States Geological Survey on the Vermilion district (Monograph XLV), prepared by J. M. Clements, under the direction of C. R. Van Hise, chief of the Lake Superior division of the Survey. From this publication, chiefly, and and from the writer's personal observations, the following general description of the methods used in these typical mines is prepared. The cuts are from the monograph mentioned.

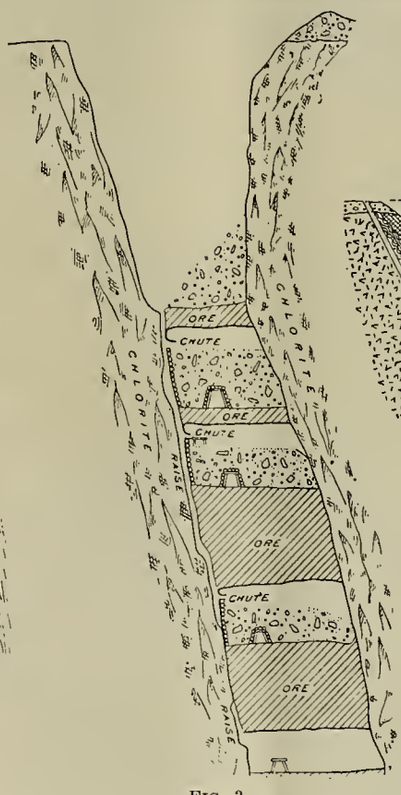

FIG. 3.

shows best the development of the "overhand stoping" system and may be taken as a type of this kind of mining.

The ore deposit of the Tower mines occurs in a synclinal and is separated by intercalated igneous sheets into a number of irregular ore bodies, one above the other. These ore bodies are more or less lenticular in shape and dip steeply to the north at angles of from 65° to 80°. The country rock is greenstone, but the igneous dikes, altered to chlorite,

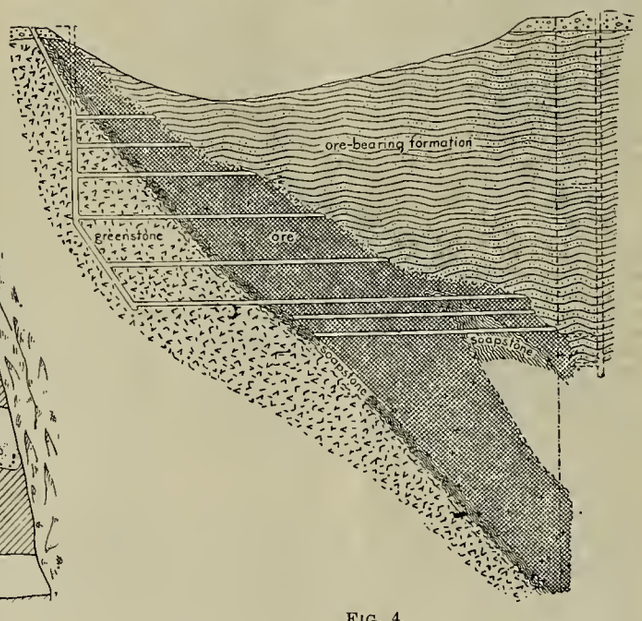

FIG. 4.

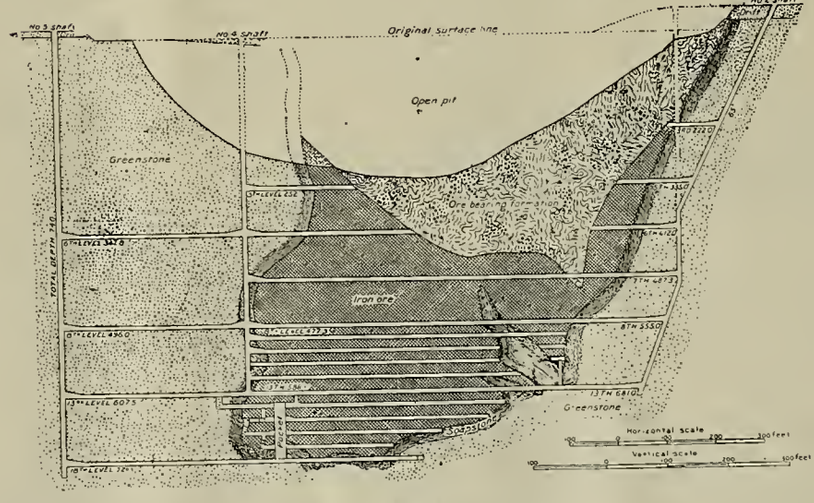

FIG. 5.

The Minnesota mine, near Tower, is really several mines operated as one. The No. 8 shaft of this mine

usually form the immediate contact. Sometimes the ore bodies are surrounded by the material of the iron formation proper—that is, cherts, jasper and interbanded hematite. The ore is hard, blue hematite.

The deposit outcropped on the hill and was first exploited by means of open pits. These were carried to a depth of 150 feet, when it was found advisable to resort to underground mining.

The No. 8 shaft, here described, is the deepest of these workings, being 926 feet in depth. This is a slightly inclined shaft and is sunk in the foot wall rock, sufficiently removed from the ore deposit to insure stability. Crosscuts are run from the shaft into the ore at intervals of 75 feet. The crosscuts, or levels, are extended to the hanging wall. A gallery 15 to 20 feet wide is stoped out in the ore body and across it. Drift sets, consisting of legs 9 feet long and 15 to 20 inches in diameter, with 11-foot caps, 16 inches or more in thickness, and heavy lagging, are erected in the gallery, extending from the foot wall to the hanging wall. After the timbering is completed filling is begun. In a like manner drifts are run along the strike of the ore deposit, connecting with the crosscut where it enters the ore body. Timbered ladderways and chutes are built up from the main drifts to a few feet above the drift sets. The space from which the ore is removed is then filled with waste rock, covering the drift sets with several feet of filling. The rock for the filling is obtained from cribbed raises, which are cut in the foot or hanging wall in the country rock along the contact with the ore. These raises extend to the surface and between each level. The rock from these raises is dumped from chutes direct into the space to be filled, or into tram cars for transportation to more remote places. By filling the raise with rock to the desired level, or by raising a temporary floor of timbers, the rock from the raise is diverted at any desired level. The rock obtained from the excavation of these raises and from the contact walls of the deposit is usually soft and easily broken down. Rock for the filling of the topmost level is obtained from the sides of the open pit. When an upper level is worked out the filling may be run into the level below.

The miners stand on the filling, or on platforms sufficiently near the roof to reach the ore and to break it down with tools or blasting. A slice of about 10 feet of the ore is blasted down from the roof. This is broken up and thrown into ore chutes or mill holes, by which it reaches the main levels, where it is loaded by gravity into bucket cars for transportation to the surface. The mill holes are placed about 25 feet apart and the men can throw the ore into them without tramming or second handling. At present the cars are hauled to the shaft by mules, but electric haulage is contemplated.

By this general plan the ore is worked out of the upper levels and the work is carried on in the lower levels simultaneously and independently.

Diamond drills are used at this mine for boring holes for blasting. This is the only mine in the Vermilion district using diamond drills for this purpose, but it is claimed that the hardness of the ore and the long holes drilled justify their use.

The several drawings herewith illustrate the general methods. Fig. 1 shows a cross section of shaft No. 8 to the eighth level. The various stages of the timbering are shown in the different levels. Fig. 2 represents a longitudinal section along the vein, the cribbing, ore chutes and filling being shown, also the methods of attacking the ore. The dotted lines indicate the raises in the walls through which the filling is introduced from above. Fig. 3 is a cross section showing the raise and levels in different stages of the work. The raises serve as a connection between the levels, and with the surface, as an escape in case of accident to the main shaft. Independent safety shafts are also provided, as shown in Fig. 1.

The Chandler mine of the Ely group is an example of the "caving" system, which is also used in the Pioneer and some of the other mines on the same deposit. The formation and the ore are similar to that at the Minnesota mine, except that the ore is naturally brecciated, which fact has been taken advantage of by the operators, and a system of mining developed which merely continues this natural process of brecciation and thereby reduces the cost of mining the ore. The ore at Ely lies in a trough of greenstone, pitching to the east at about 45°. A layer of sheared and altered greenstone about 25 feet thick lies between the ore and the massive greenstone. A cap of fractured iron formation, consisting of jasper, chert and ore bands, fills the trough above the ore body.

There are two general adaptations of the caving system in use in the Chandler mine. Above the eighth level the main levels are 75 feet apart and four series of sub-drifts are run between each main drift. Below the eighth level intermediate drifts at intervals of 20 feet are run, with no sub-drifts, and with stations at the shaft for each intermediate level. In the upper part of the mine two main drifts are driven from each level approximately parallel and on opposite sides of the ore block. From these main drifts, at 50-foot intervals, raises are put up, from which the four sub-drifts are run. The main drift is timbered with sets of 9-foot caps and 7-foot legs, and the sub-drifts with sets of 6-foot caps and 7-foot legs. This leaves about 8 feet of ore vertically between the sub-drifts. These sub-drifts are begun at the top and the ore is extracted successively until all above the main level is removed. The last step in any sub-drift is to slice the pillars and cave the backs of ore. The overlying rock and sand are then permitted to cave and the process is repeated for the next lower block of ore. The ore descends by gravity through chutes to the main drift, or level, where it is automatically loaded into tram cars and hauled to the shaft.

In the lower part of the mine the general procedure is the same, except that no sub-drifts are run, and a vertical thickness of about 10 feet of ore is broken down between the top of the sets of each intermediate level and the floor of the one above. This modification avoids the necessity of putting up raises and the ore can be loaded into cars more easily.

The naturally broken ore of the Chandler is further brecciated by the pressure of the load, and for this reason the caving system here has peculiar adaptation. Where necessary, machine drills are used in driving the headings.

An idea of the general plan of the Chandler mine can be obtained from the two cross sections shown in Fig. 4 and Fig. 5. The first is an east and west section, and the second a north and south section.

Both of these mines are considered models for the opening up of a large body of ore where the obtaining of a maximum amount of ore at minimum expense is desired.

The several cuts also illustrate the relations of the Vermilion ore bodies to the underlying greenstone rocks and the iron formation proper.

UNTIL 1900 the miner's inch was indefinite, varying in different districts. California and Montana have adopted 1.5 cubic foot per minute as the legal inch.

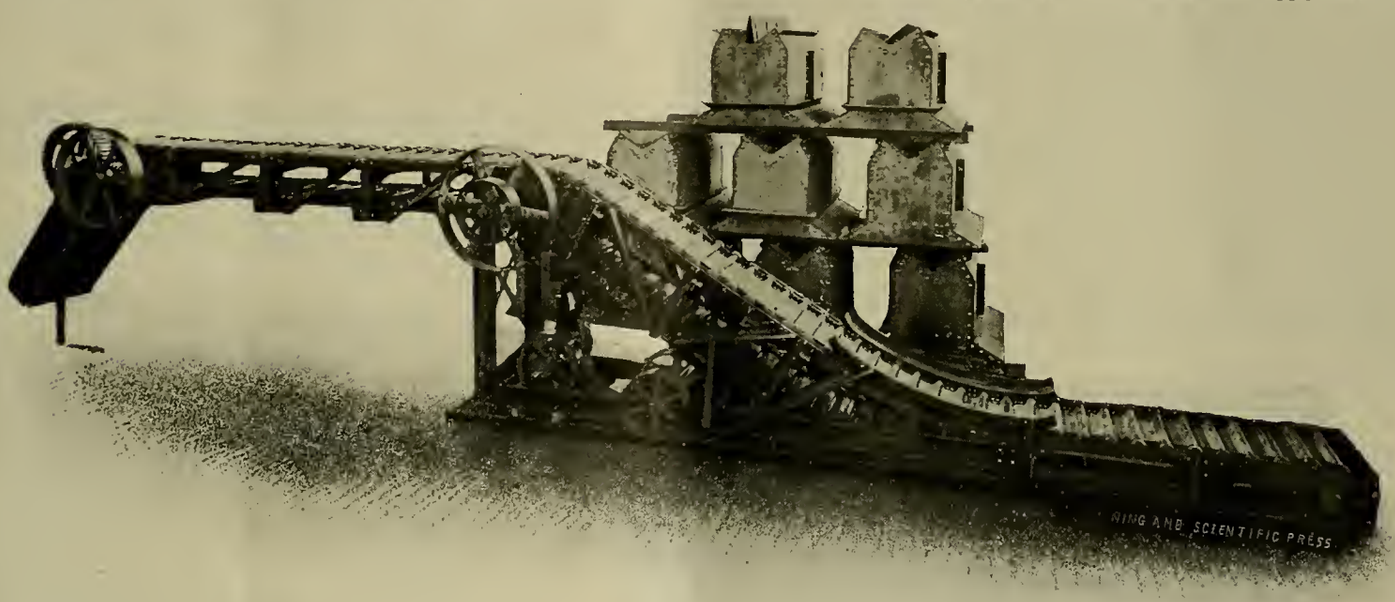
A Unique Loading Machine.

At the Empire Tunnel Co.'s property, Georgetown, Colo., is an unusual device in the shape of a loading machine. The vignette herewith is engraved from a photo furnished by the Link-Belt Machinery Co., of Chicago, and the accompanying description is from the Georgetown, Colo., Courier:

"A loading machine, the only one of its kind in the world, arrived at Empire on Tuesday of this week, and was at once transported to the buildings of the Empire Tunnel Co., at that place. This machine was built from specially designed plans, and it is claimed will do the work of eight men with one operator. It was built by the Link-Belt Machinery Co., of Chicago, under a guarantee that it would work successfully, and was secured at great cost.

"It is claimed that there is not another mine in the entire West to-day that has a loading machine, and it is doubtful if there is one in the world. It was in a peculiar manner that the Empire Tunnel people secured this labor-saving device. Some time ago a mining man made the remark in Georgetown that a machine could be so constructed as to load the rock from the blow-out in the breast of a tunnel. He outlined his plans so clearly that the Empire Tunnel Co., through its secretary, Clarence Jarbeau, at once communicated with the Link-Belt Machinery Co., asking if such a device was to be had on the market. An answer was received stating that nothing of the kind was known so far as that supply house was concerned, but at the same time they asked to be furnished rough plans in regard to its construction. The same were forwarded, drawn on the lines suggested by the party above referred, and in the course of a couple of weeks word was received from the house that the machine could be successfully built. An order was at once placed and the result was looked forward to with eagerness. On Tuesday the machine arrived, and mining men who have examined it state that it will be a pronounced success.

"Few people outside of the mining world have any conception of what a loading machine will mean in driving a tunnel through the mountain. That it will stimulate work wherever placed cannot be doubted, principally on account of the great saving to be made. The machine will be set up in front of the cars, and by working a lever will lower itself, gather up all loose rock and dump it in the cars. Thus it will be seen that no muckers will be necessary, save that of the man who is in charge."



Loading Device for Ores, Etc.

Electric Firing in Shaft Sinking.

A recently published account of shot firing by electricity in shaft sinking at the Sherwood colliery, Nottingham, England, describes the various operations there as follows:

The whole of the shot firing required during the sinking operations at this colliery was done by electricity. A shaft-sinking frame was employed, suspended from the surface, on which the compressed air rock drills that were employed were carried. Twenty-two holes were drilled at the same time in the bottom of the shaft, vertically downward, six in a circle of 4 feet radius, and sixteen outside of these, in a circle of 9 feet radius, all the holes being 6 feet deep and 2 inches in diameter. All the twenty-two shots were fired together, and twenty-four horizontal holes in the side of the shaft were then drilled,

in a circle of 11 feet radius. These were all fired together, and it is stated that the blasting left the shaft quite clean, no dressing having to be done afterwards by the pick. The total sinking to 1400 feet only occupied fifty-four weeks—a very creditable performance, indeed, and a great advance upon the previous records, due evidently to the intelligent use of the electric shot firing. The shaft bottom was lighted during the sinking by six incandescent lamps of 32 C. P. each, held in a special fitting, and suspended in the shaft by an insulated and protected cable.

Coated Gold.

In milling gold ores and cemented gold-bearing gravel the millman is often greatly troubled by the occurrence of gold which does not yield readily to amalgamation, although the gold can be readily detected in a ground sample washed in a pan, and this gold will usually amalgamate, too, which makes the problem still more perplexing. The reason can be found in a careful examination of the flakes or particles of gold which have been freed from the matrix by pounding, but uot rubbing or grinding. The gold is seen covered with a film of iron rust, manganese or some other substance. Often the gold is bright, but will not amalgamate. In such case the coating is probably silica. If such gold be treated in hydrofluoric acid the silica will be dissolved and the gold will readily amalgamate. Placer miners are familiar with the black and rusty gold of the gravel beds. Coarse gold of this description is easily saved, but the smaller particles sometimes escape, being carried along by the swift current of water in the boxes, and as the quicksilver fails to hold the gold it is often lost. What is thus commonly seen in modern gulch mining also occurs in the cemented deposits of the ancient river channels. In some of them much of the gold is covered with a coating of manganese and iron, and this gold acts in the same manner as that of the recent placers. Where the gravels of the ancient channels are too firmly cemented to be readily disintegrated in a revolving mill, the stamp mill is resorted to, and the gravel goes through the same process as quartz from a vein. It is crushed in a rock breaker, passes through automatic feeders to the mortar where it is stamped in the ordinary way, being crushed to pass a screen having ¼ to

Rubber in Gravel Mill.

½ inch apertures, which gives the mill large capacity, but while the stamping removes some of the iron or manganese oxide it seldom removes all, and there is much of the gold still difficult to amalgamate. To facilitate this a mechanical device is sometimes employed called a "rubber." This is illustrated in the accompanying engraving. It consists of a frame of timbers placed in front of each battery. The rubber is suspended from iron cross rods, and is actuated by an eccentric on a shaft driven by a belt as shown in the lower part of the picture. This gives the rubber a reciprocating motion, the shoes scouring the crushed pulp as it passes underneath, and brightening any rusty gold that may be present to facilitate its subsequent amalgamation.

In quartz mills a device of this kind is not in use so far as known, but it has been demonstrated that coated or rusty gold is not brightened sufficiently by stamping alone to remove any coating preventing amalgamation. For such ores grinding pans, rotary grinding mills or even an arrastra after stampiug will usually brighten the gold sufficiently for the purpose. Rusty gold is as difficult to save by amalgamation as though it were in some rebellious chemical combination.

The Metallurgy of the Homestake Ore.*

In discussion of the paper of C. W. Merrill, under the above caption, Mark R. Lamb of Torres, Sonora, Mexico, says: I have read Mr. Merrill's paper† with much interest, and can not but accept his challenge as regards the cost of the clean-up at the Homestake mill.

If I understand him correctly, the two men take the precipitates from the presses and do nothing towards refining them. If that is so, it would correspond to the work four men do here in about eight hours—that is, to cleau the box and to place the precipitates in the driers.

In order to make a fair comparison, the bullion in each case should be stated in ounces, siuce it is as difficult to precipitate silver as gold, and our bullion is mostly silver. Bullion to the value of $50,000 is equivalent to a weight of about 2500 ounces. At our last clean-up eight standard bars, each 1100 ouuces in weight, were made, which equals a total weight of 8800 ounces. Four men had the precipitates drying by 3 P. M.

This plant, the Minas Prietas works of Charles Butters & Co., at Torres, has square-bottomed electrolytic vats, an arraugement which necessitates the handling of all the precipitates in buckets. The Butters plant at Virginia City, Nev., is equipped with conical vats, and probably could make a still better showing under similar conditions.

Another poiut is that common labor only is required. (Ordinary laborer's wages at Torres are 70 ccnts gold). I may say also that, except for the couvenieuce of the refinery, the box could be cleaned mouthly instead of bi-mouthly at only a slight additioual expense.

The comparison, if made a few months ago, would have been much more iu favor of the electrolytic process, as the tailings handled at that time contained a large quantity of copper, and the amount of zinc dust required would have been enormous.

To resume: 2500 ounces of bullion are handled by two men at Homestake and 8800 ounces by four men at Torres.

Mr. Merrill, rcplying to the above discussion, says: Mr. Lamb's coutribution to the data of clean-up costs under various mcthods of precipitation from cyanide solutions is interesting aud welcome, and, I trust, will be followed by some onc who is handling large quantities of bullion by the zinc-shavings method. At one of the largest plants in New Zealand, handling 25,000 tons per month, I am informed that seven men are kept busy constantly cleaning up the zinc boxes.

Our last clean-up at the Homestake Plant No. 1 consisted of approximately 3233 ounces of precious metals, which was removed from the presses by two men in five hours, a duty of 323 ounces per man-hour. Mr. Lamb's men, in removing electrolytic slimes, handled 275 ounces per man-hour.

I do uot know how the preseuce of silver affects the percentage of precious metal in electrolytic slimes; but in zinc dust precipitation it greatly increases the proportion of precious metal. In the case of the Montana Co.'s plant at Marysville, Mont., I recollect that, in one iustance, when we were running on comparatively high-grade silver tailings, our zinc dust precipitate from the strong solution contained nearly 40% of precious metal.

Tensioning a Circular Saw.

Some of our readers in remote places may want to straighten a circular saw. Here is one good way: Place the saw ou an anvil. Have a board fastened to the anvil and a support at the other end about an inch lower than the height of the anvil. In testing the saw let the edge marked A rest on the board and lift up edge B so that the saw will rest only at A and B. If the saw showed straight while in a perpendicular position on the floor, and shows round under straightedge when testing on auvil, like in Fig. 1, the saw needs tensiouing or dropping, and will require a lot of hammering between the lines C and D (Fig. 1).

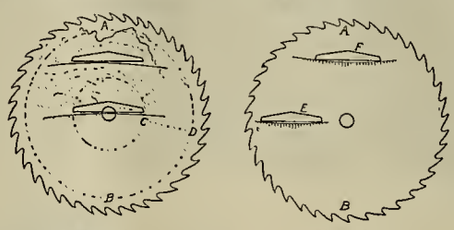

FIG. 1.

FIG. 2.

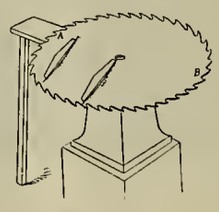

FIG. 3.

In case of a small saw, say about 16 inches, test it as in Fig. 3. A saw of this size does not have to show any tension under the straightedge, no matter where applied, if lifted as iu Fig. 3; it must show straight. Use a straightedge not longer than half the diameter of the saw, square across, and where a lump shows hammer it down, going clear around the saw, then turn it over, leveling down lumps wherever you see one. Always make your tests in the dotted portion of saw, as shown in Fig. 1. Keep this up until all high places have disappeared.

After you have the saw level, after thoroughly trying both sides, it will be nearly ready to run. If by placing straightedge, as at E (Fig. 2), it shows straight, and by pressing down a little with your thumb it opens up, as in F, all around the saw on both sides, and about half as much if the same straightedge is applied across the eye, you will find that the saw will do good work after being properly set and filed.

Large circular saws are treated just the same, but the amount of tension required can only be determined when size, speed and power are known.

Value of Molybdenum Ores.

The rapidly increasing use of the metal molybdenum in the manufacture of tool steels, armor plate, etc., says the Imperial Iustitute Bulletiu, has necessitated the discovery of some method by which poor molybdenum ores may be concentrated to contain at least 50% of the metal, since ores less rich than this can not be profitably smelted. Molybdenite, the principal source of molybdenum, is found widely distributed in various localities in New Brunswick, Ontario, Quebec, and British Columbia and elsewhere. It occurs in association with quartz and also in granites, gneiss and pegmatites, associated with pyrites, mica and other minerals.

So far the mineral has generally been concentrated by hand picking. Several methods have been devised for the mechanical concentration of the ore and some recent experiments in this direction made by J. W. Wells of the Kingston School of Mines appear to have met with success. The method is simple and depends upon the fact that molybdenite which passed through rolls does not become pulverized, but separates into flakes, while the accompanying minerals are crushed to powder. As an illustration of the application of the process, it may be stated that a sample of ore containing 50% of pyrrhotite, 10% of pyrites and 6.5% of molybdenite, in addition to calcite, mica, quartz, pyroxene, etc., after passing through rolls and being screened through a 0 2-inch sieve, furnished 1.4% of flakes, consisting principally of mica and molybdeuite. After a second screening through a 0.10-inch mesh, a further 1.54% of material of similar composition was obtained. The two concentrates in each case contained about 55% of molybdenite and 45% of mica.

To separate these minerals several methods were tried; but the best results were obtained with the Wetherill magnetic separator, which removed practically all the mica and gave an ore containing 90% to 91% of molybdenite.

Mining Summary.

Specially Compiled and Reported for the Mining and Scientific Press.

ALASKA.

The following table of receipts and expenditures on the Ready Bullion and Mexican mines, on Douglas Island, are from an official source:

ALASKA MEXICAN G. M. CO.

Statement of receipts and disbursements for year ending Dec. 15, 1903:

RECEIPTS.

18,776.04 ounces bullion from 239,453 tons ore, @ $1.407 per ton	$337,106.73
4,981.88 tons concentrates from 239,453 tons ore, @ $1.562	373,973 09
Sulphurets saved, 2.08%.	
Value of sulphurets per ton, $75 08.	
Total of all receipts	$711,079.82
Total @ $2.969 per ton	$711,079.82

DISBURSEMENTS.

Mining:	Per Ton.	Total.
Development, 8153.3 feet	$0 647	$154,912 70
Stoping, 239,453 tons	0 658	157,533.25
Milling 239,453 tons	0.276	66,183.17
Sulphurets, expense at Douglas Island	0.014	3,301 77
General expense at Douglas Island	0.029	6,984.36
Total operating expense at Douglas Island	$1.624	$388,915.25
Estimated freight and treatment charges	$0.161	$38,708.07
Expended on construction accounts	0.069	16,603.38
Estimated London, Paris, San Francisco offices, and con. engineers' expense	0.020	4,800.00
Total of all expenditures	$1.874	$449,026.70

READY BULLION MINE.

Statement of receipts and disbursements for year ending Dec. 15, 1903:

RECEIPTS.

11,353 ounces bullion from 202,881 tons ore, @ $1.01 per ton	$204,914.03
1,084 tons concentrates from 202,881 tons ore, @ $0.6552	132,940.26
Sulphurets saved, 2.01%.	
Value of sulphurets per ton, $32.55.	
Total of all receipts @ $1.6652 per ton	$337,854.29

DISBURSEMENTS.

Mining:	Per Ton.	Total.
Developing 1,879 feet	$0.1849	$37,580.00
Stoping	0 8702	176,515.38
Milling 202,881 tons	0 3803	77,170.46
Sulphurets expense at Douglas Island	0 0178	3,505.13
General expense at Douglas Island	0.0242	4,913.97
Total operating expense at Douglas Island	$1.4769	$299,684.94
Estimated freight and treatment charges	$0.1528	$31,010.58
Expended on construction accounts	0.0350	7,095.90
London, Paris, San Francisco offices and consulting engineers' expenses	0.0231	4,800.00
Total of all expenditures	$1.6878	$342,591.42

E. B. McFarland et al. of Porland, Or., with Idaho mining men, have taken over the Petty group of mines, 70 miles from Skagway, composed of five claims, for $100,000. The company will start operations this month, with H. T. Gager as manager. The mines are located on the White Pass and Yukon rivers in Tagish Lake district, and readily accessible. The ore is gold and silver, with traces of copper and lead. The silver is in the form of black sulphide and green and yellow chlorides, with occasionally ruby silver. The veins are from 3 to 10 feet in width. The mines are above timberline, at an elevation of 4000 feet.

The smelter at Hadley, Prince of Wales island, being built hy the Alaska S. & R. Co., will be completed by March 1st and is expected to he hlown in next month. The blast furnace will handle from 400 to 500 tons of ore a day. At first they will ship matte, but expect to put in converter works later. There are hodies of copper and gold-bearing quartz ore in southeastern Alaska which will supply the smelter. At one place a vein 150 feet wide runs 2% to 6% in copper and carries $4 in gold and 2 ounces in silver, says P. Johnson, of the company. They will have barges and steamers to carry the ore from the mainland to the smelter. They expect to turn out forty tons of copper a day.

ARIZONA.

Cochise County.

The Higgins mine, near Bisbee, has partly discontinued work on development. Work has stopped on the shaft and hoth tunnels. In the crosscut where a strike has been made the work will he carried ahead. In the meantime two diamond drills, each of a capacity of 2000 feet, will he put in. The presence of water renders the use of the drill for prospecting more economical than driving or sinking. The find made is 220 feet from the surface.

Gila County.

F. Beston, of the San Carlos C. Co., on the Gila river near San Carlos, near Dudleyville, says work continues hy the Saddle Mountain M. Co., which has a bond on the group. N. H. Mellor, superintendent of the Saddle Mountain M. Co., is doing considerahle development work on the San Carlos and adjoining property. Sinking is in progress on the Apachia claim, the shaft being 120 feet deep and a winze is being sunk from the 100-foot level. On the Cannon Ball of the O'Brien group, a tunnel is being driven. All the openings are in sulphide ore of medium grade. The coal claims in the Deer Creek field, bonded to the Saddle Mountain Co., are distant 7 miles from the copper mines, and a road is now being built to connect them. It is intended to prospect the coal lands with a diamond drill.

Graham County.

H. Westlake, superintendent of the Colorado M. Co., near Clifton, reports the work of driving the Garnet tunnel progressing. Two shifts are being run, and 2½ feet of ground broken per day.

The Veiled Prophet C. Co., Ltd., has been incorporated at Clifton to develop the Veiled Prophet group of five patented claims in Greenlee district. Development work, under the management of B. M. Crawford, will be started next month. The officers of the company are M. A. Smith, W. M. Griffith, E. F. Everhardy, D. M. Potter and B. M. Crawford of Clifton.

Another 200-foot contract was let last week hy L. F. Sweeting, manager of the Polaris M. Co., near Clifton, making a total of 1500 feet under contract.

Superintendent Bennie says the Shannon C. Co. smelter's converter plant, near Clifton, will be ready for operation hy June 1st. It will have capacity of twenty-five tons per day.

Maricopa County.

(Special Correspondence).—The Wickenburg smelter has been hought hy the White Tanks M. Co. —— A. Salina is working a claim near the Garcia mine in the Vulture mining district.——F. Nicholas is working his claims near the Trilby mill. He has ore out which he will ship to the smelter.

Work will be resumed at the Gold Quarry mine, near Morristown, next week. A contract has been let for sinking a shaft.——The Arizona M. & D. Co. is working men at the Rylands mine, near Morristown.

Wickenhurg, Feh. 14.

(Special Correspondence).—G. Francis is putting in a gasoline hoist on his mine, 5 miles west of Morristown. —— R. E. Humphries says he will put men to work on his claims this week.——B. Johnson and J. Smith have located a claim near Seymour, on the Hassayampa river.—— D. Cleherat & Co. are making preparations to cyanide the tailings at Smith's mill, on the Hassayampa river below Morristown.

Wickenhurg, Feh. 15.

(Special Correspondence).—S. S. Moore of New York, secretary of the Relief G. M. Co., operating near Wickenhurg, states that the mine is ready for a mill, which will he huilt the coming season.

Wickenhurg, Feh. 15.

Mohave County.

Work will he increased on the Great West mine, near Kingman, says H. H. Smith, resident manager. It is intended to put in machinery for the mine and to increase the output of the mill. The Great West mine is in Blue Ridge range.

F. E. Griffith of the Philadelphia & Arizona M. Co., operating near Kingman, says he has arranged for resuming sinking at the mine. Electric machines will he used. The mill has been overhauled and the jigs will not he used.

Pima County.

The Helena G. M. Co., owning and operating the Helena group, near Greaterville, is preparing to put in Huntington mills to replace the small mill used to demonstrate the value of the ores. The group comprises 100 acres of mineral land with hodies of free milling ore, and is near the Greaterville placer workings.

Pinal County.

(Special Correspondence).—The mines of Lampker & Hunstock, north of the Superior group, near Superior, has heen bought hy W. Graichen for $30,000.

It is reported that a vein of sulphide ore 8 feet in width has heen struck in the Alice tunnel at Troy.

Superior, Feh. 15.

G. W. Wallace and H. Whitburn, of Duluth, Minn., have taken charge of the Copper Butte mine, near Florence. They have started work on a douhle-compartment shaft which will he sunk to depth of 500 feet.

Santa Cruz County.

Z. F. Rawson, superintendent of the World's Fair mine at Harshaw, says his company is sinking a 1000-foot shaft on that silver property.

Yavapai County.

Superintendent H. LeMontayne of the Sultan mine, near Hillside, says he is resuming work on the property, and more men will he put on.

The Groom Creek Co. (formerly the Alhua claim), at Groom Creek, is operated by Hall Bros., and they have driven their level at 200 feet for distanco of 600 feet. They are sinking and raising, and as soon as they breah through they will nado this their main working shaft. A boiler and hoist with 700 feet of cable will be put in. They aro taking out ore regularly, and have a pack train packing ore to the Gold Basin mill. They have a pipe line laid over the mountain to pump water from the shaft to the Gold Basin mill.

The Central Arizona M. Co., G. G. Green, superintendent, is putting up a milling plant on its President mine, near Martinez.

The Buffalo-Arizona M. Co. is operating 3 miles from Poland, with D. Rice, of Idaho Springs, Colo., as superintendent. The mines are on the east slope of Mount Union, on headwaters of Turkey creek. ——G. W. Middleton, manager of the Bradshaw Mountain C. M. & S. Co., which bought the Val Verde smelting works at Val Verde, will make improvements and increase capacity of the plant. —— Superintendent Campbell, of the Stark G. M. Co., near Prescott, says the company's mill is in full operation.

CALIFORNIA.

Amador County.

The mill at the Bunker Hill mine at Amador City was started up this week, says Superintendent Downs.

The Imperial mine has been sold to the Burlington M. Co. of Calaveras county, F. O. Courtmarsh of Glencoe superintendent. The Imperial mine is 1½ mile east of Sutter Creek. The Burlington Co. will develop the property. Hoisting works will he put up and a two-compartment shaft sunk.

At the Oneida mine, near Jackson, operations continue steadily, producing 7200 tons of ore per month. The winze being sunk 400 feet north of the shaft at the 2000-foot level, for prospecting purposes, is down 100 feet. It will be continued to the 2200-foot level. The electric cahle to furnish power for the pump heing set up has been put in place.

Butte County.

The Steifer M. Co., composed of Corning men and operating at Nimshew, has opened into the gold-hearing channel in its drift mine.

Calaveras County.

At the Gwin mine, at Gwinmine, F. F. Thomas, manager, the main and south shafts are sunk to a depth of 2000 and 1600 feet, respectively, and the hoist and mill of 100 stamps are in operation. In addition to the gold saved on the plates, there are forty Frue vanners collecting concentrates. Both the hoist and mill are run by water, the former having a head of 330 feet and the latter 400 feet. After using the water for these purposes it is carried 1 mile down the gulch, and there reused to compress air for the drills and pumps. As a safety measure, a boiler plant of three boilers has been completed to furnish steam in case anything should prevent use of water. The hoist at the main shaft is douhle, having lifting capacity of four tons 2000 feet at rate of 1500 feet per minute. The gallows frame is all steel, and measures 118 feet in height from the collar of shaft to roof. The ore is dumped from the skips onto two rock breakers, and then automatically loaded into 3-ton cars, and trammed hy mules into the mill. At present, the ore heing treated is taken from the 1600 and 1700 foot levels. A crosscut is being run for the ledge at the 1900 foot level. The shoot being worked is 60 feet in width. They have 250 men at work. At the south shaft no ore is heing taken out, though it is heing repaired and a douhle reel hoist set up. The water from the mine is handled with pumps, operated hy compressed air, with a capacity of 250,000 gallons per twenty-four hours, and in case of temporary disability to them two skips are used that hoist each 1200 gallons.

El Dorado County.

The New Highland G. & C. M. Co. has had men at work huilding an extension to the debris dam on Mameluke hill, near Georgetown, and has everything ready to start operations as soon as the permit from the Debris Commissioners is obtained. With the men the company has at work on the Porter and Holmes claims, twenty will he on the payroll, says Superintendent Parker.

At the Eureka-Woodside gold quartz mine, near Georgetown, heing operated hy El Dorado C. M. Co., the work of sinking the triple-compartment shaft is progressing under Superintendent W. E. Everson. The shaft is down 160 feet.—— Work on the ashestos mine, owned hy El Dorado C. M. Co., is progressing.—— The tunnel at the Ford copper mine is heing driven ahead and it is expected the ledge will he tapped this week.——The Georgetown Gazette says with the work heing done on other mines in that district, and also in Bear Creek, Josephine, Garden Valley, Greenwood and Kelsey districts, the mining outlook on the Georgetown divide is promising.

The 1-stamp double discharge mill at the Deutscher Bund mine, in Poverty Point district, near Placerville, was started up last week.——The Rescue gold-bearing quartz mine will be developed under superintendency of A. Anabel of Placerville. A shaft has been started and ground is being graded for a steam hoist.

Kern County.

President J. M. Wright of the Peerless and Fulton oil companies, operating at Kern river and Sunset, says on the Peerless one crew will be kept at work, but further than this no development work will he done for the present. The production of the Peerless wells during the month of January was 190,000 barrels, the contract with the Standard calling for 150,000 of this number. The receipts from sales were $38,000. At the Fulton six wells are completed. The first reservoir, with a capacity of 107,000 barrels, is finished and is heing filled.

The Flamioflume M. Co., which has been operating at Jawbone canyon, near Randsburg, has closed down. —— The New Century group of claims, uear White's Camp, has heen located by T. McCarthy and C. Taylor, and development work is being done.

Nevada County.

G. W. Root of Grass Valley has a bond on the Seven-Thirty quartz claim at Deadman Flat, in Rough and Ready district. He will, as soon as the weather permits, put up machinery, including a compressor, and sink a new shaft. The mine is owned hy the Evening Star M. Co. of San Francisco. It has heen developed to depth of 185 feet.

O. Coffin, superintendent of the Central Con. mine, with others, has honded the quartz mining claims on the Jennings' ranch at Banner mountain, near Nevada City. Jennings reserves the agricultural rights. These claims are north of and adjoining the Central Con., which is being operated.

The 10-stamp mill at the Federal Loan mine in Willow Valley, near Nevada City, is again in operation. Ogden Bros., who have had a hond on it for some time past, have succeeded the Eastern company that operated it for several months. There will be seven men employed at the mine, and ore will he taken from the 600-foot level.

At Rough and Ready the property of Black Bear M. Co. has heen sold to H. Fleischaker et al. of San Francisco.

F. P. Hall has purchased the J. A. Meighan interests in the Brophy mine at Shady creek, near Nevada City, and the company is being reorganized. Work will be resumed.

S. K. Murchie of San Francisco has hought the Native Son group of five mining claims in Blue Tent district, near Nevada City. He will hegin development next week.

Placer County.

The Hidden Treasure M. Co., near Michigan Bluff, is having a model of its mine made, which it will send to the St. Louis Exposition. The model will be a complete representation of the mine, even to the running of ore cars.

Plumas County.

On the south side of Grizzly Ridge, near Quincy, and owned hy C. Trimhle, C. McHugh, W. J. Schneider and W. Whitaker, the Cataract quartz mine is being developed.

San Bernardino County.

(Special Correspondence). — Manvel is the center of a district which seems just awakening to its possibilities. The Santa Fe from Goffs has a hranch line to Ivanpah. Barnwell (Manvel postoffice), the principal station, is 30 miles from Goffs and 15 miles from the Ivanpah terminus. From Manvel stages connect for Searchlight, Nev., 25 miles easterly, and Sandy, 60 miles northeast. The Clark road crosses this hranch line 8 miles above Manvel and passes within 16 miles of Searchlight. Construction work is under way and the promise of the early completion of this line is stimulating prospecting and the mining husiness generally.

Four miles north of Manvel is Vanderbilt camp, where the Gold Bronze M. Co. has a 10-stamp mill and a mine in which considerahle work has heen done down to the fourth level. The property is now tied up hy litigation. It is owned hy J. M. Hale of Los Angeles.——The Camphell group is also at Vanderhilt. Its principal workings are on the St. George and the Boomerang. On the latter is a 10-stamp mill, hut is at present idle, pending negotiations for a sale, which are said to be under way.——Near Vanderhilt a location has heen made hy W. Oshorn for O'Meara & Lynch of Tonopah, Nev., which is heing developed. He is sinking

a two-compartment shaft and the outlook is favorable.

Manvel lies noar the foot of the New York mountains, a group rising out of an elevated mesa, attaining an elevation of about 7000 feet. In area they are 5 by 9 miles. On the eastern slope is the Alpha group of claims, owned by the New York Co., of which H. Schrader and T. A. Johnson of Los Angeles are principal owners. On these about 3000 feet of work has been done, though temporarily idle. They propose building a smelter. In this canyon are other prospects, as yet only partially developed.

Over the range, to the south, is the property of the Giant Ledge Co., L. M. Gregory of Los Angeles president. The property comprises 800 acres of ground and includes a valley running down to the level of the plain, which will afford a spur from the Santa Fe branch easy access to the proposed mill, which can be reached by aerial tramways from the mines. The Giant ledge in places crops out 60 feet in width. Wherever opened up it has disclosed bodies of ore carrying copper, gold and zinc. It has been undergoing development the past two years in conformity to a systematic plan. In one place the ledge crops 70 feet above the surface. From the canyon intersecting tunnels have been run. Across the valley, below the millsite, runs a dike which brings the underground flow of water to the surface and provides natural advantages for treating the ores. A test shipment of zinc ore is being made.

Between Manvel and the New York mountains the Trio M. Co. is opening up a ledge of copper carbonate that at a depth of 100 feet has been crosscut for 14 feet without reaching the wall.

The Keystone mine, near Sandy, belongs to the same New York company as the one above mentioned. At present it is not working to its capacity. It also has a 10-stamp mill.

Manvel, Feb. 15.

Siskiyou County.

The Mono M. Co. proposes building a 12-stamp mill at its Punch Creek group of claims on Humbug creek, near Yreka. It will be operated by electricity.

M. Jacobs, C. Beisel and L. Marinel of Spokane, Wash., have taken over the Mount Vernon group in Siskiyou county for $35,000. Development work consists of 2000 feet of underground work. They intend to put up a 10-stamp mill with concentrators. It is a free gold proposition.

J. Johnston, part owner of the Headwaters quartz mine on Humbug creek, near Hawkinsville, has started development work.——A. C. Brokaw bas men steadily at work taking out quartz at the Golden Eagle mine on Indian creek, near Fort Jones, the ledge being 4 feet in width. He expects to put up a mill in the spring. Brokaw is also working his hydraulic claim in Quartz valley with good success, having abundance of water for elevators and giants.

Tuolumne County.

W. S. Wilhelm is operating the Kœnig mine near Parrotts ferry, near Columbia. —— M. R. Clement has bought an undivided two-thirds interest in the Toledo and Big Indian quartz claims, 2 miles southeast of Tuttletown.

The Hope mine, near Sonora, owned by San Francisco men, is being operated under Superintendent Corrigan. He has the mill ready to run. The tunnel has been retimbered and a shaft has been started, which will he put down to strike the vein below the tunnel level.

Superintendent De Sallier bas men at work at the Kanaka mine, near Groveland. A general overhauling will be made, tracks laid, etc , and more men will be put at work next month.

The 5-stamp mill at the Longfellow mine, near Groveland, is in operation. They are milling the ore that was left in the old ore bin, by which time the balance of the machinery will be on the ground, when they will shut down to strengthen the ore bin, place the rock crusher, compressor, engines, machine drills, etc. A 30 H. P. gas engine and pump are on the ground. Wood is being cut sufficient to last until arrangements are completed for the use of crude oil, says Superintendent Partington.

The mill is running steadily at the Mount Jefferson mine at Groveland. Sinking operations have been discontinued temporarily until the compressor is set up.

Yuba County.

At Camptonville, M. F. Hrubanik and W. A. Newsom, who have bonded the Honeycomb mine, are arranging to reopen the property. Tbo mill will also be started up.

Men have been at work dismantling the dredging boats on Bear river of tbe Bear River M. Co., near Wheatland, and the machinery has been shipped to Oroville, where it will be utilized in repairing boats thero of tbe same make. The buckets, which weigh 550 pounds eacb, were considered too light for the work on the Bear. One boat, with 1100-pound buckets, remains. Drillers are at work and dredging is expected to be resumed when heavier boats, adapted to conditions on that river, have been built.

M. Ramsey, superintendent of the Whitney mine, near Cabbage Patch, near Marysville, has put men to work and has development under way.

COLORADO.

Chaffee County.

The Buena Vista M. Co., composed of Buena Vista men, has bought the Hancock, Reliance and Kathleen mining lodes in Hancock mining district. They are near the Camp Sherrod mining district. The company will put in machinery and start development work. C. A. Smith of Denver is manager.

Clear Creek County.

(Special Correspondence).—The Bullion King mine is under lease to W. Bennett, wbo is taking out fifteen tons of ore per month. The ore is sulphide of lead, but contains considerable zinc, which is extracted before shipping. The vein is 2 feet in width. The shaft is 400 feet deep, but the work is being done between the second and tbird levels.

Tbe Santa Fe M. & M. Co., on Alpine mountain, is driving two adit tunnels. The lower one will cut the vein 300 feet below the surface. Leasers are at work on an upper adit taking out ore.——The Waltham M. Co., H. T. McNoil, superintendent, is building a testing plant. They expect to increase the capacity the coming summer.

Idaho Springs, Feb. 15.

(Special Correspondence).—The sale of the Pelican-Dives' Seven-Thirty group of mines, near Georgetown, was for between $300,000 and $350,000, the option having been held by J. F. Brandes of Denver and J. H. Eaton of Louisville, Ky., for Kentucky and New York men. Part payment has been made, and further payments will bo made this year. The property comprises eighty-eight patented claims, covering 250 acres, has 16 miles of underground work, and a recorded production of over $12,000,000 since its discovery in 1869.

Tbe oro averages $75 per ton in silver, lead and gold values. Bodies of smelting ore are blocked out; but the future profits are expected to come mainly from the concentrating ore, which has been allowed to accumulate in the stopes and on the dumps. To handle this ore a 300-ton mill will be built. It is intended to do away gradually witb the leasing system. There are 100 men at work, but this will be increased to 250 within the next year.

It is also intended to complete the Burleigh drainage tunnel this year, and make connection with the bottom of the Seven-Thirty shaft. This will drain and ventilate the entire group and reopen the Seven-Thirty's lower workings. Hoisting will he stopped, and the ore taken out through the Burleigh tunnel, at the mouth of which the mill will be built. O. O. McReynolds is manager at the mines.

Denver, Feb. 15.

The Gold Mountain group in Atlantic district, near Georgetown, has been bought by W. S. Leebrick. It consists of six claims and development work bas been done.

The Shafter M. Co. near Idaho Springs has bought ground for erection of a mill. The site is near the Jackson and Newton mills, and also near the Tanner cyanide mill. Manager A. H. Roller says he expects to have the mill completed by the time the Central tunnel cuts the Shafter lode in June. The mill will have a capacity of sixty tons a day.

Custer County.

A 1-foot vein of black oxide of copper is reported from the Louella mine, 2 miles from Silver Cliff. This ore body was opened in a drift run 32 feet from the 200-foot level of the shaft. The ore carries gold, silver, lead and copper values. The mine is under lease to Thomas, Wolff & Coughman.

El Paso County.

Work on a plant for treating the dust obtained from the ores milled at the Telluride plant has been started near the site of the Telluride plant in Colorado City. The process used will be a pneumatic cyanide method. The building will be 60x60 feet square, three stories high. It will have a capacity of fifteen tons of dust a day. The builders are said to be H. B. Haigh et al. They will treat the dust already accumulated, and that produced by the new companies in tbeir operations. The experimental plant and assay office of the General Metals Co. has been added to and remodeled.

Fremont County.

Six new coal mines are being opened up in Fremont county, says the Times. All of tbem will be in shape for production next fall. One of these mines is being opened by striking coal miners. The mines being opened are the Purity Oil Co. of Denvor, working south of Rockvalo; J. Ridle, working south of Florenco; F. P. Smith & Sons, working at Williamsburg; Maupin et al., working west of Brookside.

Gilpin County.

(Special Correspondence).—Tho Jenny Creek M. & M. Co., in northern part of Gilpin county, 14 miles from Central City, on the line of the Moffat Railroad, owns 220 acres in one body. They have one shaft down 80 feet and another 60 feet, besides a prospect tunnel 320 feet in length. They have let a contract to drive another tunnel 400 feet to cut the ore body 200 feet below the surface. They expect to reach the ore body in about 200 feet. The ore is a sulphide and averages $30 per ton. They will put in a stamp mill. C. F. Peterson is manager and C. B. Frantz secretary.

Baltimore, Feb. 14.

Shipments of smelting ores, concentrates and tailings from Black Hawk depot to the Denver smelters and outside points for month of January were 194 cars or 3880 tons—an increase of six cars over the previous montb.

Colorado Springs men are arranging to resume operations on the Golden Dollar mine, near Russell Gulch, which they have under lease and bond and operating as the Quartz Hill M. Co. It is intended to sink the shaft several hundred feet.

The Alps mine on Quartz bill, near Black Hawk, has twenty men on the payroll. It is being worked by a local pool under lease and bond, and J. Williams is in charge. One and one-half cords of ore are being sent daily to the mills in Black Hawk. The smelting product has an average of $150 per ton. They expect to increase shipments.

Gunnison County.

(Special Correspondence).—Tbe West Gold Hill M. Co., operating in Tin Cup district, is working on Sellors No. 2 mine. They are in 280 feet. The ore averages $10 per ton. A carload shipped from the fissure vein averaged $20. They are drawing plans for a 50-ton cyanide mill.

I. L. Johnson is working the Gold Cup and Lee mines, on East Gold Hill, and is down 900 feet on the incline. He has let a contract to drive 150 feet on the ore body on this level.

The Blistered Horn tunnel is being driven by the Brunswick M. & M. Co. At 900 feet they cut a vein 17 feet wide said to average $17. They drifted 50 feet on the vein and report striking a 12-inch streak that runs 500 ounces in silver and $10 gold per ton. Tbey expect to cut the Gold Cup and Lee mines on East Gold Hill before completing the tunnel.

Tin Cup, Feb. 15.

Manager Lockwood of the Brooklyn M. Co., near Elko, reports his tunnel and compressor buildings finished and the machinery in successful operation. The air drill is working and they are breaking from 3 to 4 feet of ground per shift in the tunnel.

Hinsdale County.

The Hidden Treasure mill, at Lake City, is in operation putting it in for the leasers who are breaking ore in lovels 1, 2 and 7.

Jefferson County.

(Special Correspondence).—The Oro G. Dredging Co., with headquarters in Chicago, Ill., is preparing to put up two 2000-yard dredgers on Clear creek, 2 miles from Golden. Tbe company has an option on 2900 acres extending 5½ miles on the creek bed. It has drills at work prospecting the gravel.

Golden, Feb. 14.

Lake County.

The lease on the Sixth Street shaft at Leadville having been transferred to the Midas M. Co., development and output will be increased. With the Coronado, the Midas and the Sixth Street in its combination, the Midas M. Co., Nicholson & Rodman managers in charge of operations, will be in position to develop more extensively than before tbe iron deposits that exist in the downtown section.

The Banker M. Co., at Leadville, will resume operations. The Banker shaft on Breece hill is near the Penn and the Ibex No. 4 shaft. There is said to be a body of copper sulphide in sight, carrying values in gold, silver and copper. The plans of the company include installation of a plant of machinery for development work.

Work has begun on the Penrose mine at Leadville. The work being done consists in pulling the pipes from the shaft. The old machinery will be taken out and a new plant set up. There are four lines of pipe running down the shaft, two for steam and two for water. The Midas M. & L. Co. is the operator, with D. E. Jones as superintendent. The shaft will be retimbered. President S. D. Nicholson of the Midas M. & L. Co. says the plans include sinking of the Penrose and Coronado sbafts through the parting quartzite to the Cambrian quartzito. The Penrose shaft is down 640 feet and the Coronado about same depth. Both will be sunk from 200 to 250 feet farther. In the meantime shipments from the Coronado and Midas will continue, the iron deposits in these properties being drawn upon to maintain output. The Coronado and Midas are shipping 250 tons a day. It is not the present intention to do any work on the Sixth Street shaft.

Sao Juan County.

(Special Correspondence). — The San Juan S. & R. Co., operating the Henrietta and otber mines in the San Juan, has completed an aerial tramway from the Henrietta mine to the railroad. The company intends starting the smelter at Silverton next month. The company owns 450 acres of ground, and on the Henrietta has over a mile of drifts, tunnels and shafts. A concentrating mill is under consideration.

Silverton, Feb. 14.

The pumps have been pulled from the Old London shaft, at Mineral Point, near Silverton, and the men discharged.

The Little Maude group of mining claims, near the head of Maggie gulch, near Silverton, owned by Born & Abbey, is being worked by Rice Bros. & Moreland under bond and lease. The bond calls for $85,000, with 50% net royalty on all ores extracted. This group is a producer of gold and silver ores. The lessees are making regular shipments. The group is developed by several openings on the vein and by a crosscut tunnel which cuts the Maude at a depth of 185 feet below the surface. A new tunnel will be started 200 feet below No. 1 tunnel. The vein is 12 feet wide. The ore shoot, 18 inches wide, is of brittle silver (stephanite), with some pyrite in a quartz gangue.

The Cortland group of seven claims on tho south slope of Tower mountain, near Howardsville, will resume. The owners are Louisville, Ky., men.

The Boston & Silverton M. Co., A. A. Lamont superintendent and manager, owns thirty-four claims in one group on the west slope of Boulder mountain, up Cement creek, 3½ miles from Silverton. The Yukon tunnel has reached a depth of 1850 feet and has cut a vein of ore on which drifts are being run. Tbe Lamont tunnel is in 900 feet and as soon as milling ore is struck a tram will be built to the mill, a distance of 4160 feet. The mouth of the Yukon tunnel and the mill are near the Silverton, Gladstone & Northern Railroad, and tbe road has a branch line to the ore bins.

San Miguel County.

E. M. Titus and W. Hutchinson, developing the Jumbo lode in Bridal Veil basin, near Telluride, report work progressing. They have men driving a tunnel on the vein, which is in 240 feet. They will continue the drift until depth of 500 feet is attained.

At Ophir Loop, the Butterfly-Terrible and the Silver Bell plants are running steadily, with fifty men at the former and twenty stamps dropping in the mill. Manager Keating says the steam plant put up during the property's idleness is being used as a motive power in tho mill, conserving the water supply for concentration purposes.

The number of men employed at the Smuggler-Union mines at Telluride is being increased, says Manager B. Wells. Three levels are being worked and the number of stamps dropping in the mill ranges from twenty to fifty. Concentrates are being shipped regularly.

With fifty men employed, the Nellie mine, near Telluride, is running steadily. The mill has twenty stamps dropping. About May 1, Manager C. Anderson says he will increase the number of men and start twenty more stamps in the mill. At present the Nellie trail between the mine and mill is impassable, and no effort will be made to clear it. Men going to and returning from work are transported on the tramway. Operations are under way on only two levels of the Nellie, but in the summer all six levels will be worked.

Summit County.

Another gold dredging company is preparing to operate in Breckenridge district. B. S. Revett et al. have organized the Reliance G. Dredging Co. under Wyoming laws and have bought the Jackson placer (the Magnum Bonum and Corkscrew), in French gulch, at Breckenridge, and expects to bave a dredger operating by July 1.

Teller County.

The recent strikes of high-grade mineral in different sections of Cripple Creek district are being made use of by the mining companies, says the Record, for demanding more exacting terms and conditions in granting leases, chiefly in percentage of royalty demandod. Where a flat royalty of 25% was previously considered a maximum, graded royalties are now demanded with 25% as a minimum, ranging as high as 50% on ores above a

certain value. Restrictions are embodied in recent leases as to depth, the company reserving right to operate below specified level to which the lessee is restricted, whether operator opens a bonanza or expends his money without return. Notwithstanding these exactions, there is still a strong demand for ground, and the number of properties that are being developed by the leasing system is on the increase. The Anaconda estate of 100 acres, on Gold hill, has thirty-five sets of lessees at work and has every block leased.— It is said the Hoosier mine, on Tenderfoot hill, will start up again.

The following table shows amount and value of Cripple Creek ores treated during month of January by different mills and smelters:

Plant—	Tons.	Value.
Smelters	10,000	$650,000
U. S. R. & R. Co	23,000	575,000
Portland	8,500	255,000
Dorcas	2,000	104,000
Telluride	4,000	100,000
Economic	2,500	60,000
Cyanide plants	1,500	9,000
Totals	51,500	$1,723,000

El Paso mine, on Beacon hill, Cripple Creek, sent out 3000 tons of ore during month of January. This will be increased during present month. The value of the ore shipped is said to have averaged $40 per ton.

The Requa Savage M. Co. has granted a bond and lease on part of its Gold King claim on Gold Hill, Cripple Creek, to F. A. Wright of Gillett for 75,000. The part under bond is three acres in extent, adjoining the Progress King, Lexington and others. The Gold King claim has several shafts, the deepest being 500 feet. Wright has started work.

Last week the mines of Cripple Creek paid out on their January payrolls an aggregate of $500,000. The total would have been $50,000 more, says the Times, but for the fact that the Stratton's Independence laid off all its men at the time of the accident, two weeks ago, so the property with 500 men had a short payroll.——The Strong mine management voluntarily increased the wages of its men 50 cents per day, all around, for the month. The men have been getting the regular schedule of $3 and $3.50 per day. There are eighty men at work, says Superintendent S. McDonald.

The Eagle sampler at Cripple Creek is treating 225 tons of ore per day. It has twenty-five men at work and this number will be increased, as the night shift is working three nights out of the week at present. President Franklin, manager of the sampler, says he expects to treat during the month 9000 tons of ore. Every sampler in the district is running full capacity.

IDAHO.

Blaine County.

The Red Elephant mine, near Hailey, has been unwatered and it will be retimbered and reopened.

Boise County.

F. Burbridge and A. Burch have a bond on the Iowa mine at Quartzburg, in the Boise basin. Development work has been started under Superintendent W. P. Belding.

The Ingle Co. will resume operations in the Twin Sisters mines, at Centerville, next spring. Men are cutting wood for fuel for hoist and mill.

Elmore County.

M. Mayfield of Boise and H. Crah of Atlanta report work progressing on their Gold Bug claim in Black Warrior district, below Atlanta. When the tunnel was driven 141 feet a 5-foot ledge was struck that assayed $60. They have five claims on the ledge and have opened it in fourteen places. The ledge was cut at depth of 100 feet in the tunnel. One hundred and thirteen claims have been located in the district. The country rocks are phonolite and granite.

Idaho County.

Near Elk City the Homestead group of mining claims has been bought by the Leroy M. Co. for $50,000, says W. H. Plummer, of Spokane, Wash., secretary and manager of the company. The company owns the Lerey mines also near Elk City, on which it has built a 10-stamp mill and is going ahead with development work. It is proposed to put in a small stamp mill on the Homestake. M. T. Newlon, of Philadelphia, Pa., is the president of the company.

The Grangeville Standard reports the consolidation of the three groups of copper holdings on the Salmon river, near White Bird— the Idaho C. M. & S. Co., the Salmon River C. M. & S. Co. and Mineral Zone C. M. & S. Co. The plan is to dam the Salmen river for power supply for a milling and smelting plant. The properties are 15 miles from Grangeville, on both sides of the Salmon river.

In Black Lead district of the Bitter Root range, McConnell & Co., of Moscow, are preparing to build a mill at their mine. The Black Diamond and Black Hawk claims, adjoining the Black Lead mine, have been bonded to J. M. Smith et al. of Lewiston.

At the Crackerjack mine, at Hump, the compressor and receiver are being set up. Two veins have been cut and drifted on, one of 12 feet wide and the second showing 26 fdet of ore by crosscut. The third, or main lead, is still 70 feet in from the end of the crosscut tunnel. As soon as the compressor is ready machine drills will be at work on this 70 feet. Electricity is used for power.

J. E. Jewell, of the Thunder Mountain Gold Reef M. & D. Co., which owns the Monumental group on Monumental creek, near Reesevelt, and the Confidence group (formerly known as the Mayflower), says work is progressing, and the company will put a mill on the Confidence in the spring.

The Dewey M. Co., owning the Dewey mine, near Grangeville, is preparing to build a concentrater plant to have capacity of fifty tons a day. The property is owned by Seattle, Wash., men, and O. Aheling is manager.

The Lucky Lad mine at Hump is shut down temporarily. One hundred and thirty feet of shaft have been sunk and 250 feet of drift run. —— The Spokane, after several years' idleness, has been worked this winter. —— The last of the Crackerjack machinery is on the ground and set up.——The Granite shaft is down 45 feet. —— J. Stone is developing his group west of Concord. He has plenty of timber and water.

The Lexington G. M. Co. has been incorporated by C. F. Allen of Clarkston, G. W. Thompson, J. C. Mayes, H. Witherspoon, A. C. Moore, T. B. Bartlett and E. A. Cox. The company owns the Lexington and Wild Horse groups in Buffalo Hump, on which development work will be started this month.

Considerable work is being done on the Del Rio mine, an extension of the Jumbo, near Hump. The latter property has been putting in thirty additional stamps. There were fourteen stamps already in the mill property, and four of these will be shipped to the Del Rio.

Placer operations on Salmon river will be increased the coming summer and a number of companies owning ground at various points are preparing for work. Among the first to start piping will be the Henrietta Co. at Riggins. This company nearly completed a flume and ditch last fall, and, as soon as it is finished, will start washing under Superintendent C. Clay. ——The Pittsburg-Idaho M. Co., which has bought the Short's Bar claims, took in a sawmill and turbine wheel last week. The mill will saw out 500,000 feet of lumber for construction of 5 miles of flume to bring 1000 miner's inches of water to the ground. After the mill is in operation, it is expected to require five months to complete the flume. The ground to be worked contains four gold-bearing channels of Salmon river, the highest of which is 400 feet above the river. The flume will deliver water 200 feet above the high channel. The company has built a wagon bridge across Little Salmon and will grade a wagon read to the mines, 1½ mile from the State wagon read.

Ore is being shipped from the Mt. Marshall group of five claims and the Sherman group of two claims in Marshall Lake district, near Grangeville. These properties are owned by J. C. Fox and P. R. Briggs. The Marshall Lake group has 3 feet of ore at the bottem of a 35-feet shaft which assays $30. The Sherman group has 7 feet of ore.

The McKinley gold mine, near Lucile, owned principally by Kellogg men, is being developed. A crosscut is being run to the vein at depth of 100 feet. This will be 140 feet long when completed, and is in 130 feet. They are running the drift on the 400-foot level. Samples of the ore from the vein 17 feet in width show $18 in gold per ton.

Shoshone County.

The Evolution mine is again in operation. A shaft house has been built and men are on development work, while preparations are being made for installation of pumps, hoist and compressor. Four claims comprise the group, which is 1½ mile below Osborne. Over 1200 feet of tunnel work have been done. It was located as a gold property, but explorations carried on have disclosed ore carrying silver, lead and copper as well. A shaft has been started 60 feet above the bed of the creek on the mountain side, expecting to strike the vein 175 feet below the creek level. The vein pitches southwest. Previous development work showed the ledge 23 feet wide between the walls. A drift of 180 feet was run on the vein. W. Osborne of Osborne is part owner.

A two-years' lease has been given O. R. Young of Wallace on the Wyoming mine on Grouce gulch, and he will start development work this week. The mine is near the Cœur d'Alene Dev. Co. in Government gulch. A tunnel is in 2000 feet. It is the intention of Young to raise from the lower tunnel.

Wallace reports state that Larson & Greenough, owners of the Morning and You Like mines at Mullan, are preparing to build an addition to their mill, to increase the capacity of the plant to 140 tons of concentrates per day. They will do away with the "slum" tanks on the outside of the mill. The building will connect the main mill building with the new vanner house. The machinery to be used will consist of eight Frue vanners, making in all sixteen vanners added to the plant in the past six months. Mill Manager W. H. Myers has introduced an improved method of draining the slum tanks in the mill, and what formerly required several hours of hand labor is now done in a few minutes by machinery. By the old method a man was required to swing a heavy iron shot against the side of the tank. In place of this, he has rigged up two drilling machines on solid blocks of wood, 2 feet from the floor, providing them with leather bumpers and air connections.

Washington County.

C. W. Jones of Weiser says he has a five years' lease of mining properties in the Seven Devils district from the American M. Co. of Helena, Mont. The mines leased are the White Monument, Peacock and Helena, carrying copper values. They are equipped with machinery in the way of hoisting works, etc. Jones says that as soon as the roads are in condition men and supplies will be taken to the camp and operations begun. He expects to put fifty men at work. On the Peacock a tunnel will be run to tap the ledge at a depth of 500 feet.

The Ladd Metals Co. has machinery on the ground for its smelter, building at Mineral. The foundations are completed. It is stated, wood alene will he used for fuel.

MICHIGAN.

Houghton County.

The report of the Quincy M. Co., at Hancock, shows: Average number of men employed, 1624; average number of miners, 586; average wages of miners on contract per month, $62; yield of mineral per fathom (6 feet) of ground broken, 443 pounds: yield of refined copper per fathom of ground broken, 325 pounds; total rock mined, 1,024,164 tons; rock hoisted, 1,006,173 tons; stamp rock treated, 958,935 tons. During the year the diamond drill was used in several different places throughout the mine; an aggregate depth of 1705 was bored, but nothing of value discovered.

The sale of the Arcadian's diamond drill last week marks final suspension of exploration on the Arcadian property, near Hancock, says the News. A cold wave and blizzard has been interfering with the rock service at all mills.

Tamarack No. 3 shaft, near Calumet, is hoisting at rate of 1100 tons, or 28 cars daily.

The Kimberly skip at Red Jacket shaft of the Calumet & Hecla mine, near Calumet, on the 13th inst. caught on an obstruction, tearing the guide rails from the 21st to the 12th levels. The compartment is out of commission.

Baltic rock shipments for January were the largest for any month since the mine became a producer, says the News, the daily average being 1900 tons. The company is no longer at a disadvantage in matter of milling capacity, and before March 1st the daily volume of rock treated is expected to reach 2000 tons. The capacity of this mine, near Painesdale, has been greatly increased as a result of the extensive development operations of the past year.

The situation regarding future of Isle Royale shaft No. 1, damaged by fire, is reported still uncertain. A contract to wall up the fourteenth level south of the shaft has been let by the company. The damaged shaft is without pumping facilities and a cement wall is being built to prevent inflow of water to No. 2. There are a number of surface openings in the ground tributary to the damaged shaft, through which water will flow when spring opens.

Ontonagon County.

The Adventure Con. C. Co. at Greenland reports for year ended Dec. 31, 1903:

Received from sales	$301,134
Running expenses	$237,413
Taxes	14,051
Smelting, transportation, etc	29,949
	$281,413
Construction account	61,611

Present operations are confined to the Knowlton lode, except one stope on the Merchant lode and four stopes on the Butler lode. From time to time throughout the year work was discontinued at the most unprofitable and unpremising points. Reduction in forces was made in August. West end of mine proved a failure and was shut down. Operations to date have shown value of lodes under Adventure bluff at shallow depth are not profitable.

The Victoria mine, at Victoria, will be given rail communication by extension of the road of the Holt Lumber Co. to the mill site. This will connect with the Duluth, South Shore & Atlantic near Ewen.

MONTANA.

Beaverhead County.

D. Hodgens of Butte has a lease on the Midnight mine, near Argenta. It is intended by Hodgens & Co. to build a cyanide plant on the Midnight to treat the low-grade ore in the mine and on the dump.

L. C. Graeter and E. I. Hall have an option on the Indian Queen mine, near Dillon, for New York men. Additions to the equipment are proposed.

Flathead County.

The total shipments for last year from the Snowshoe mine, near Libby, amounted to eighty carloads. This is for a steady run of six months. The eighty carleads averaged thirty tons to the car and the concentrates assayed $60 per ton. It is intended to put in additional machinery next spring and enlarge the capacity of the mine to produce. The new machinery will consist of additional concentrating tables and more sliming capacity, also a Huntington mill. On the 200-foot level, from which most of the ore was taken the past season, there is a shoot of ore 10 inches in width which assays $20 in gold. It is expected they will sink the working shaft additional depth, which is but 350 feet below the level of the main working tunnel. The principal values in the Snowshee have been in silver and lead. The gold values are said to be increasing with depth.

Jefferson County.

The Silica mine is 1½ miles from Basin, on the line of the Great Northern Railroad, and consists of a quartz averaging 95% silica, and carrying small values in gold, says the Basin Progress. The ore is shipped to the smelters, at Butte, for flux in treatment of copper ores. The mine is owned by E. E. Williams and D. Bevan, of Basin. Shipments of 1000 tons per month are made. The workings are open and the ledge is quarried, the practice being to drill a number of deep holes and with heavy blasts to break down from 200 to 1000 tons of ore at a shot, after which the ore is carried in cars to a chute, through which it is conveyed directly to the cars.

Madison County.

C. E. Dameurs, manager of the mines of the Damours G. M. Co., operating near Virginia City, says they propose to build a 30-ton mill on the company's ground.

Silver Bow County.

The Original Con. M. Co. has been incorporated under the laws of the State of Washington by W. A. and C. W. Clark, W. A. Clark, Jr., A. H. Wethey, A. J. Johnston and W. M. Bickford of Butte. The company is to work the Original, East and West Stewart and probably other mines operated by W. A. Clark.

NEVADA.

Elko County.

Mining at Bullion, Railroad district, 30 miles southwest of Elko, has been resumed. A company of California men has bonded the Weston & Frank group and has started work of development under Superintendent Knutzen.——Burke & Skaggs are opening up the Copper King, owned by them, showing a ledge of ore. ——The Charley Bressmer group, under bond to a company of Elko men, headed by A. W. Hesson, has been worked for the past year and development is going ahead.

Esmeralda County.

The main shaft in the Montana-Tonopah mine at Tonopah has reached depth of 735 feet, and only 50 feet of sinking remains to be done when a station will be cut and a new crosscut run north. The north crosscut from the 600-foot level is in 425 feet. The east and west drifts on the McDonald ledge from this level are in 70 feet and show a good face of ore. On the same ledge in the 500-foot level the west drift is in 240 feet and working in high-grade material. The raise from this drift is up 70 feet, and from it ore is being extracted. In the east tunnel leading to the North Star shaft a track has been laid and ore is being taken from the ledge cut in the North Star at 950 feet and which in its western course enters the Montana ground. Shipments of ore are going forward regularly, increased railroad facilities on the Carson & Colorado having been obtained.

Ore is being taken out and sacked for shipment from the ledge cut in the mine of the Tonopah-Gold Mountain M. Co. at Gold Mountain, southwest of Tonopah. The ore is said to average $140 per ton in

gold and silver. Several lessees are at work on the property and taking out ore.

Humboldt County.

Preparations are in progress for increased work by the Glasgow & Western Exploration Co. of Salt Lake City, Utah, at Golconda, where the company's furnaces are built, says Manager Stalmann. The smelter will go into operation with the thawing out of waters on which it is dependent. An electrical process, tested by the management with satisfactory results, is being added to the plant. With this equipment the plant will be prepared to treat 100 tons of ore daily, and with a steady supply of water. At the mines of the company work has been progressing steadily under Superintendent J. Farren, new ore bodies having been added to the supply. At the Adelaide group, the Copper Mountain and Copper Basin groups the work has opened smelting ore.

Lincoln County.

The Pioche-Nevada Con. M. Co. has heen incorporated at Salt Lake City, Utah, to operate the West Point group of claims, 2 miles from Pioche and on the road to Calientes. The officers are J. M. Burton, J. Zink, R. W. Brady, F. B. Steelo, F. L. Gardiner, C. E. & R. L. Rives.

White Pine County.

The Giroux Con. C. Co. continues work on its copper mines at Ely. Development is progressing. J. L. Giroux is manager.

NEW MEXICO.

Grant County.

The Ontario M. Co. will begin work on its property, near Lordsburg, April 1. The shaft will be sunk to depth of 600 feet. W. Davis and J. G. Pehler of Wheeling, W. Va., are directors in the company.

The Colorado F. & I. Co. of Puehlo, Colo., owns a number of claims in Fierro district, among them being the Anson S. and Iron Head. The ore mined by this company is all iron ore, and is shipped to Pueblo. The company has a crusher at Fierro, through which all the ore mined is run before shipment, putting it in shape for the smelters without further treatment. There are 200 men employed at Fierro, hut at present everything is at a standstill owing to the coal strike. As soon as the strike is over it will resume operations. Shipments during last summor averaged thirty cars of twenty-five tons each.

The Burro Mountain C. Co. bas been incorporated oy N. F. Leopold and A. C. Schwah of Chicago, Ill., and T. W. Carter of Silver City. They have a lease from the Southwestern C. Co. of all the mining property owned by that company in the Burros, consisting of nine patented and four unpatented claims. They will build a concentrating or leaching plant of at least fifty tons capacity per day. The lease includes an option to buy. This group has been supplemented by buying a number of adjoining properties, the principal of which are the Sampson, Loma Alto, Fanny, Last Chance, Copper Bell, tbe Sampson millsite, the Comstock, Celebrated Day, Favorite, Enterprise, Golf, S. T. and Any Old Thing, the J. H. Lester, the Fancy millsite, McKinlek, Clara and the Candlestick mines. The Southwestern C. Co. properties and the Sampson group are producers. T. W. Carter is manager.

The Hanover M. & M. Co. owns a concentrating plant in Hanover gulch, 1 mile south of Hanover, equipped with rolls, Huntington mill and concentrating tables, which is under lease to and operated hy F. Higgins. He is running it on silver-lead ores from the Surprise mine. The high-grade ore is shipped and the low-grade ore is heing run through the concentrator with satisfactory results, producing high-grade concentrates averaging 60% lead, with silver values. The Surprise is owned by J. W. Bible and is operated by Higgins under lease. It is opened up by a tunnel, cutting the ore body 90 feet below the surface. A crosscut 30 feet in length has been driven without reaching the hanging wall. The ore is galena. ——The Honeycomb copper mine (formerly the Humboldt), owned by the Hanover M. & M. Co., is being developed by a shaft 110 feet in depth and 1000 feet of drifts and crosscuts, exposing ore hodies. A recent shipment of 100 tons ran 12% copper, besides gold and silver values.

Santa Fe County.

At the cement placer gold fields of the Interstate Placer M. Co. at Golden, men are at work sinking shafts to hedrock to test the gold values of the cement. —— Men are opening new ground at the San Lazarus, near Golden. A cyanide mill will be erected.

T. P. White is working his gold properties near Golden and the Argo M. Co. has men at work on the Hazelton group. A shoot has been uncovered on the 400-foot level.

OREGON.

Grant County.

E. G. Stevenson, part owner of the Monitor mine, near Susanville, says the 5-foot Huntington mill is set up, but is not running yet, as the tailings to be treated are frozen. The first work to be done is the running through of 3000 tons of tailings. After the tailings have been disposed of the mill will treat the ore from the mine. For this a rock breaker will be added.

Superintendent McGuigan of the Alamo mine, near Granite, says the ten stamps are dropping steadily on ore. Power is furnished by three separate water motors. One runs the ore crusher and ten stamps; another the two concentrating tahles, while a third, a smaller wheel, runs the dynamo for lighting. Between thirty-five and forty tons of ore are heing milled per day. The stopes in the mine are being opened up. Stoping is heing done ou No. 2 level, from where there is a chute 480 feet to No. 3, or the mill level. As yet there has heen nothing taken from Nos. 1 and 3.

Jackson County.

The Omaha G. M. Co. is developing a quartz property near Gold Hill, on Foots creek, under superintendence of C. C. Clark. Two tunnels have been driven on the ledge—one to deptb of 270 feet and the other 235 feet. The ledge is 3 feet in width and gives average assay values of $12 in gold.

Josephine County.

The Eureka mine, on Soldier creek, near Grant's Pass, is being operated hy its former owners of Eureka, Cal., under management of A. F. Nelson. A 10-stamp mill is operated.

The Conner hydraulic placer on Briggs creek, near the mouth of Red Dog creek, near Grants Pass, is heing operated by Brinegar & Smith. They are working in the channel uncovered by Conner.

The monthly output at the Greenback mine is reported at $40,000. The property is on Grave creek, near Grants Pass, and has been producing for three years. W. H. Breevort of New York is president and C. W. Thompson is manager at the mine. The manager reports arrangements completed for heavier production this year than last. The mill has forty stamps.

Malheur County.

It is reported Manager J. F. Meikle of the Black Eagle mine, near Malheur, is arranging for building a 100-stamp mill in addition to the present 20-stamp plant.

In the Malheur district, 4 miles from the Black Eagle mine, near Malheur, the Uncle Sam group of ten claims has heen taken over by G. S. Stanley for Cadillac, Mich., interests. It is intended to build a 20-stamp mill. A hoist of 20 H. P. is being put on the shaft, that is 160 feet deep. A 60 H. P. steam plant will be put in for the hoist.

SOUTH DAKOTA.

Lawrence County.

(Special Correspondence).—The mill of the Tinton Tin Co. has been completed and was put in partial operation on the 11th inst. A series of experiments are being made.

Tinton, Feb. 14.

Pennington County.

The Golden West M. Co. is putting up a saw mill at its mine in Hornhlende district, says E. J. Kennedy, secretary and manager. A Chili mill of 100 tons daily capacity will be put in by the company in the spring and the saw mill will cut timber and lumher for the mill and other huildings. There is a Chili mill of five tons capacity on the property. There will be built in connection with the quartz mill a system of cyanide vats for the retreatment of sands. The ore of the Golden West is free milling. The Golden West Co.'s holdings consist of the Benedict and Yellow Bird groups, on Castle creek, 5 miles southwest of Rochford, and this stream will furnish water for power purposes.

TEXAS.

Hardin County.

Development of the Batson Prairie oil field, near Sour Lake, is progressing. Operations have been under way hut three months and eleven producing wells have been completed, and nine additional wells are expected to reach the strata this week. The wells which are producing are distributed among the following operators: Paraffine Oil Co., four wells; J. M. Guffey Petroleum Co., three; Honeymoon Oil Co., two; W. B. Sharp & Co., one. Tbree of these wells, viz., two owned by the Guffey Co. and one owned by tbe Paraffine Oil Co., are producing from the shallow strata. and have not heen drilled to the deeper oil sand. On Jan. 31 only four wells were producing, their combined output being sufficient to overload the pipe line facilities of the field. Thirty thousand harrels per day are their combined deliveries at present.

UTAH.

The month of January in the ore and bullion market closed on settlements aggregating $1,790,100, a gain over corresponding period of 1903, says the Tribune, though receipts from the various camps have heen interfered with by the weather. Stock on hand kept the furnaces in blast. The output of the copper bullion containing gold and silver during the month exceeded all previous shipments by the plants in Salt Lake valley to the Eastern refineries, reaching a total of 3,478,150 pounds, of whicb 2,803,150 pounds came from the independent plants. The value approximates $750,000.

	Pounds.
Bingham Con	720,000
Utah Con	1,300,000
United States	783,150
American S. & R	675,000
Grand total	3,478,150

To increase the output of copper the Utah Con. at Bingham will have soon completed enlargements that will enable it to reduce 800 tons of ore daily, while the Bingham Con. has a fourth furnace to go into operation. To meet the requirements of the valley furnaces in January the mines supplied 90,776 tons of ore, while in addition to this there was forwarded to furnaces outside of the State 6000 tons of ore.

Beaver County.

The Old Hickory and the Harrington-Hickory mines of the Majestic C. Co., at Milford, are closed down. There are a few men continuing work on the O. K. mine of same company. Financial trouhles are said to he the cause.

Box Elder County.

P. W. Madsen of Salt Lake City, manager of the Century mine at Park Valley, says ore has been struck in the crosscut run to the north from the main workings. The vein averages 6 feet in width and the ore assays $12 in gold. The mill is in steady operation with sixteen stamps dropping. J. H. Clark is superintendent.

Iron County.

The Johnny mill at Stateline is heing put in operation again. Developments in the mine since the close down have heen satisfactory, and ore has been blocked out.

Jnab County.

January shipments from Tintic district were:

	Cars Ore.
Ajax	8
Bullion-Beck	20
Carisa	14
Continental-Eureka	232
Dragon Iron Mine	50
Eagle & Blue Bell	4
Gemini	27
Grand Central	81
Lower Monarch	67
La Clede	1
South Swansea	10
Salvator	2
Star Con	4
Uncle Sam	11
Uncle Sam (concentrates)	2
Tetro	13
Victor	2
Yankee Con	23

Salt Lake County.

The Columbus Con. M. Co. has bought the Webster & Kearns mill at Park City, and as soon as tbe roads at camp permit will ship the machinery to its millsite in Little Cottonwood canyon, near Alta. The plant has a crushing capacity, says Manager Jacohson, of 150 tons daily, with two tables and three sets of jigs. Another table will be added to the battery and another set of jigs.

The Utah C. M. Co.'s new mill in Bingham canyon, near Bingham, is expected to be put in operation this week, says Superintendent Janney.

The Copper Prince Con. M. Co. has been organized at Salt Lake City to operate in Little Cottonwood district by T. Jacohson, C. K. McCornick and C. H. Post.

The Copper Belt railroad is said to bo moving an average of 750 tons of ore from Bingham daily, equal to 22,500 tons per month. This output will be increased. This does not comprise the entire output of the camp, however, as the tramways and other methods of transportation are carrying about 40,000 tons per month.

Manager Caitrow of the Ohio C. Co.'s mines at Bingham says the Winnemuck mill of the company is daily turning out 20 tons of concentrates from 125 tons of crude ore.

On Antelope island, in Great Salt lake, near Salt Lake City, the Fountain Oil & Asphalt Co. is preparing to start drilling operations for oil and gas. It has acquired by lease and otberwise over 6000 acres on the north end of the island. The company has heen incorporated by local and Ohio men, with T. P. Steffey of Salt Lake City president and R. M. Edmunds, J. B. Hall, E. Wilkes and E. J. Raddatz as officers.

The building of a concentrator at the Continental Alta mine, at Alta, in the early spring, to be followed by erection of a power house on Little Cottonwood creek, near Wasatcb, is announced by H. M. Crowther, manager the Continental M. & S. Co. The concentrator will have an initial capacity of 100 tons a day and will be used at first for handling the sulphide ores from the lower levels. The matter of handling the "sand carhonate," carrying values of silver and lead in the upper workings, will be disposed of later, after tests bave been made as the hest manner of reducing them. The power plant will havo capacity of 500 H. P., and the power will be conveyed 8 miles up the mountain hy wire and then used to operate the mine and mill. The question of transportation by electric power instead of the wagon road method now used will he taken up.

San Pete County.

The Oriental Utah M. & M. Co. has heen organized at Scofield, Carbon county, to develop mining properties in Nebo Basin district of San Pete county. J. S. McNeal is president, with T. Kelter, H. C. Lee, N. M. and A. Madsen officers. A. Madsen is manager.

Sevier County.

President P. A. Franklin of the Gold Dev. Co. says next month its general offices will be removed from Salt Lake City to Richfield, near which are its mines.

Summit County.

The station has been finished and the pump placed on the 700-foot level of the King Con. mine, near Park City, says the Park Miner. This pump works automatically by means of a butterfly valve and float, so tbat the services of pumpmen are not required. Sinking has been discontinued until the pipe lines leading to the pump on the 700 level have been placed. These consist of 4-inch and 6-inch pipes and will replace the small ones temporarily used to take care of the water. Superintendent Keetly says the water will be lifted by the pumps on the 700-foot level to those on the 500-foot level. Electric lights will be placed in the levels and will be used to work hy in the shaft. To do this a reel will be placed on the 700-foot level so that the lights may be lowered as the shaft goes down. When firing the lights will be hauled up. They will be protected by wire masks. Heretofore the water at all times present has caused trouble to the men in keeping their candles hurning.

The compound engine for the Daly-West slimes plant at Park City is being set up. It is of 125 H. P. capacity and will be used to drive the dynamos which are to run the machinery of the plant. The tanks are in place and the tables are heing set up.

Tooele County.

The Sacramento M. Co. of Mercur produced seventy-seven flasks of quicksilver during month of January, besides the usual output of gold. The ore which is being mined runs very well in mercury, while the average of that which went through the retorts last week was 26.5%, says Manager Bothwell.

The properties of the Overland M. Co. at Sunshine will be reopened under the direction of E. W. Clark. The mill will he overhauled and additional equipment put in.

Utah County.

It is reported the Silver Dipper mine at American Fork will be equipped with a mill this spring, The Silver Dipper has hodies of low-grade ore exposod in its workings. L. G. Hardy, manager, says in addition to the milling ores that carry values in silver and lead, and that might be profitably shipped without concentration with more favorable facilities for transportation, the company has developed first-class ore that will be shippod as soon as the roads permit.

WYOMING.

Albany County.

It is reported the New Rambler copper mine in Douglas Creek district, near Laramie, will resume operations this month, the property having passed to the possession of the original owners. During the past few years cobalt, platinum, iridium and other minerals have been found in the ores of the New Rambler.

FOREIGN.

The European production of quicksilver for year 1903 is reported as follows:

Country.	Metric Tons.
Spain	930
Austria	520
Italy	270
Total	1,720

The output of the Spanish mines shows decrease from 1902, while Austria and Italy show slight increase.

AFRICA.

Transvaal.

A petition containing 45,100 signatures

of white men have been forwarded to the government, praying for the passage of a law favoring and making possible the employment of Asiatic unskilled labor. The petition has been presented in legislative council at Pretoria.

AUSTRALIA.

Western Australia.

The gold output of Western Australia, by months, for 1903, compared with 1902, was:

	1903		1902	
	Tons.	Ounces.	Tons	Ounces.
January.	158,069	181,173	125,359	143,822
February	160,939	187,771	140,600	158,108
March	179,888	195,541	148,914	166,812
April	171,880	201,885	112,852	158,938
May	169,558	178,287	151,538	171,813
June	166,405	*224,026	157,236	173,185
July.	185,458	161,681	167,617	174,194
August.	183,775	183,707	167,719	182,591
September	183,567	186,088	173,377	186,965
October	185,072	188,262	169,233	188,057
November.	183,176	188,360	165,044	187,037

*Including 38,921 ounces which belong to previous returns, but, having been omitted, are herein included.

The management of the Lake View Consols mine at Kalgoorlie is making additions and improvements to the gold saving equipment at its mill. The motive power is being increased. Twenty stamps have already been replaced in the mill of the Lake View. In the mine itself, at the 1400-foot level, the development drive on the main Lake View lode will be extended farther. On the Perseverance lode at this level, where general mine work is in progress, about 500 feet south of the Perseverance Co.'s boundary, encouraging results are showing in the workings.

The Great Boulder mine at Kalgoorlie has cut the vein at 1750 feet, where it is stated to be 23 feet wide, averaging about $20 per ton.——It is stated that ore reserves in the Kalgurlie mine have been materially increased by recent development. A long drift is being run south to reach the Oroya-Brownhill shoot. The sinuous windings of this ore shoot have greatly puzzled the engineers in charge of the mines of the district. Some weeks ago the indications were that the shoot was passing into the Associated's ground. The Associated obtained permission to prove the northeast portion of their property from the Oroya workings. This proved that the shoot had unexpectedly turned westward in the direction of the Kalgurlie.

BRITISH COLUMBIA.

East Kootenay District.

C. M. Edwards, operating a placer mine on Moyie river, near Fort Steele, has stopped work temporarily, pending the arrival of hoisting machinery and pumps.

Nelson District.

The 2-mile tramway to the Hunter V. mine at Ymir is completed and shipments of ore have begun. It is a double-rope tram, with a capacity of 400 tons of ore a day. It is expected shipments will be 80 tons a day. At the mine the ore is being quarried out from the deposits and conveyed by subsidiary trams to the main tramway. It is said to be a desirable smelter flux. The British Columbia Standard M. Co. owns and operates the Hunter V.——At the Foghorn mine developments are said to be showing a body of pay ore. The end of the 1200-foot crosscut tunnel is 250 feet east of and 900 feet beneath the ore exposed in the prospect shaft. A drift is being run toward the shaft and has gone 120 feet. The face shows 6 feet of ore averaging $10 a ton. The vein is the third one opened in driving the crosscut.——At the Dundee mine operations are in full swing. The drifts and stopes have been cleaned out and high-grade ore is being broken down for shipment.

Rossland District.

J. Kirkup, government agent at Rossland, reports to the Bureau of Provincial Information the following is the scale of salaries and wages being paid by Lo Roi M. Co. at Rossland:

	Per Month.
Superintendent	$300 00
Office manager	300 00
Bookkeeper	125 00
Clerk	100 00
Surveyor	125 00
Timekeeper	100 00
Storekeeper	100 00
Mine foreman	175 00
	Per Day.
Shift bosses	$ 5 00
Timber boss	4 00
Machine men	3 50
Timber men	3 50
Blasters	$4 and 3 50
Skip tenders	3 50
Cage tenders	3 50
Cage helpers	3 00
Car men	$3 and 2 50
Shovelers	3 00
Nippers	2 50
Track men	3 50
Pipe men	3 50
Pipe men's helper	3 00
Pump men	3 50
Scavengers	3 00
Diamond driller	6 00
Diamond drill runner	4 00
Diamond drill helpers	$3 and 2 50
Sampler	4 50
Aerial trammers	3 50
Waste trammers	3 50
Sorter boss	4 00
Crusher men	2 75
Sorters	2 50
Feeders	3 50
Master mechanic	6 00
Millwright	4 00
Electricians	$3 50 and 3 00
Machinists	$4 and 3 50
Machinists' helpers	3 00
Machine repairers	3 50
Boiler makers	4 00
Hoist engineer (large hoist)	4 00
Hoist engineers (other than above)	3 75
Compressor engineers	1 00
Firemen	3 00
Wipers	$3 and 2 50
Oilers	3 00
Blacksmith foreman	4 50
Blacksmiths and drill sharpeners	4 00
Blacksmiths' helpers	3 00
Blacksmiths' helpers (underground)	3 50
Carpenter foremen	5 00
Carpenters	3 50
Framers	3 50
Framers' helpers	$3 and 2 50
Watchmen	3 00
Yard foreman	3 00
Laborers	2 50
Teamsters	3 00
Messenger	2 00

NOTE.—Underground men work eight hours per day; surface men, with exception of the following, work ten hours:

	Hours.
Hoist engineers (small hoist)	8
Compressor engineers	12
Firemen	12
Carpenters	9
Electricians	9
Watchmen	12

The tonnage of ore shipped from and crushed at the Rossland mines for month ending Jan. 30 was as follows:

Mine.	Tons.
Le Roi	24,260
Center Star	5,850
War Eagle	4,860
Kootenay	1,030
Jumbo	1,325
Le Roi Two	1,940
Le Roi Two (milled)	1,180
Spitzee	30
Total	40,475

Mining and development work is temporarily suspended at the Kootenay mine at Rossland. Shipping of ore will be maintained through February. The mine has considerable tonnage of ore broken down in the stopes. Filling the stopes with broken ore instead of timbering has resulted in the mine having a large surplus ready for drawing off in all the stopes, and it is this material that is being shipped. Diamond drill exploration has also been discontinued. No further mining will be done at the Kootenay, says the Rossland Miner, until the question of reduction works is settled.

Vancouver Island.

The Tyee C. Co. reports the increasing output of its Tyee mine at Mount Sicker has made it necessary for the company to increase capacity of its tram line. The work is completed and the company is shipping 200 tons per day from the mine to E. & N. Railway, thence to the company's smelter at Ladysmith. Work at the mine is progressing steadily. The Van Anda mine will ship its output to Ladysmith to extent of 15,000 tons of ore per annum.

The Yreka mine at Quatsino is again in shipping condition. Operations were hindered during the past season by scarcity of water. The number of men at work has been increased. February 1st there were 500 tons of ore on the dump ready for shipment. N. Tregear is manager.

FRANCE.

A British company, incorporated as La Mangiarde, Ltd., has obtained mining concessions from the Government to operate in the Department of Alpes Maritimes, and has started work at La Mangiarde, near La Tour-sur-Tinee. They are operating at an elevation of 5412 feet above sea level, where copper croppings have been located. Machinery will be put in.

MEXICO.

Chihuahua.

W. P. Dunham of Los Angoles, Cal., E. Smith of Denver, Colo., and R. H. Reid, have bought La Esperanza mine in the Consuela group, near Terrazas, for $1,200,000. La Esperanza is at northern extension of the Dolores mines of the Venture corporation of London. The new owners of La Esperanza own the Pinos Altos. They have also bought a piece of ground at south extension of the Dolores for $250,000. Work will begin next week.

The Occideutal S. & R. Co. has been organized to take over the Creel smelter at Chihuahua hy E. Creel of Chihuahua, S. Chase of Portland, Or., W. Selover et al. The plant will be remodeled and capacity increased from 200 tons to 700 tons.

N. C. Thompson, manager of the Candelaria M. Co., says additional pumping machinery will be put in at their mines at San Pedro.

The Kentucky-Mexico I. Co. has been incorporated in Louisville, Ky., by members of La Luz G. M. Co., operating at Maguarichic. The following are officers: S. L. Pearce, J. J. Kavanaugh, C. W. Stark, W. D. Pearce, H. D. Rodman and M. O'Doherty. W. D. Pearce is manager. This company will take over and develop certain gold and silver properties held by W. D. Pearce at Manterde, 100 miles southwest of Minaca, near line of the Orient road, and some properties at Maguarichic.

It is reported the Candelaria mine of Storer & Partridge in Parral will be started up next week.——A diamond drill is in operation on the San Carlos mine, adjoining the Tres Mercedes mine, near Parral. The property consists of 23 pertenencias. It is owned hy B. Davis, Noake & De Smeth et al.

Durango.

The Bacis G. & S. M., Ltd., of London, England, is developing properties in district of Santiago Papasquiaro. 192 kilometers west from Durango. The holdings comprise 94 pertonencias. The ore, which carries silver and gold, is reported to run $30 per ton. Development consists of twelve tunnels driven a total of 10,800 feet, besides 2555 feet of drifts and crosscuts. The tunnels cut the ore bodies at depth of 1200 feet below the surface. Equipment consists of a 30-stamp mill (650 pounds per stamp), one Bryan mill, twenty-eight 4-foot Frue vanners, two boilers for heating pans. The plant is run by water power through medium of turbines which develop a total of 150 H. P. The company proposes putting in a cyanide plant and additional power equipment.

Guerrero.

J. F. Dowling of the La Dicha C. M. & S. Co. says they are preparing to increase equipment at their mines at La Dicha.

Jalisco.

Additional machinery will be put in by the Amparo M. Co., near Ezatlan, including an electric lighting plant and a lumber mill, says Superintendent G. J. Graham.

Manager F. W. Page of the Mexican M. & S. Co. at Masoota says he is preparing to build a smelter.

Lower California.

As a result of the strike in the Esperanza mine, owned by J. A. Mendoza, south of El Triunfo, the mining industry in Lower California is improving, says Modern Mexico, and prospecting is being carried on extensively in the hills, especially on placer lands. There are a number of paying mines, such as the San David, Aurora, Purisima, Telemaco, Penelope, Viznaga, Ulises, Moctezuma, Texas, etc. Silver mines have been worked near La Paz for several years and exploitation of copper mines has heen carried on successfully in Santa Rosalia district, in the municipality of Mulije and in San Fernando. The principal mining concern in the peninsula is El Boleo, in Santa Rosalia, owned by the Rothschilds. This company employs 3000 men. It has smelters and a narrow-gauge railroad, which runs from the mines to tho furnaces. Its annual production averages 11,000 tons of copper. Sulphur deposits are found on the Gulf coast of the peninsula. Seventy-five miles southeast of Ensenada indications of petroleum have heen found. The turquoise mines at La Jara are in operation. They are owned by a Colorado company. Lower California principally produces silver and copper.

Sonora.

The Tarasca G. M. Co. reports work progressing on its mines, 10 miles north of Torres. Development is said to have opened up 597 feet of the ore body. They are taking out and sacking 1000 tons of ore for shipment. It is intended to build a mill at the mine, as they have ample water rights. From the bottom of the vertical shaft, a crosscut has heen run east 390 feet to cut La Miniatura and La Tarasca veins. The principal workings are on El Ubarbo vein where a vertical shaft cuts the vein at depth of 200 feet. Below that point, an incline goes down on the vein for 150 feet. From the shaft a drift is run 400 feet northwest on the vein, and 200 feet southeast. The north face shows 2 feet of ore. There are extensive "antigua" workings. The company's holdings cover 120 acres. R. Barnett is superintendent.

President W. Greene says the output of the Greene Con. C. Co., at Cananea, in January was 5,000,000 pounds, and the operating expenses for the month were $392,000, which included some charges for improvements. He says the actual cost of mining the company's copper for the month was 7 9/16 cents f. o. b. mines. To this must be added $1.57 a hundred for transportation. For the four months ended Nov. 30 it cost the company 10⅛ cents f. o. b. to mine copper.

It is reported that the Rey de Oro M. Co. proposos building a 10-stamp mill near Magdalena.

The Imperio de Cobre M. Co. is developing a copper property in Arizpe district, south from Cananea, and has twenty men at work. The ores run 8% copper and 20 ounces silver per ton. A. Goldbaum of Hermosillo is president and S. Cohen is general manager.

It is reported the Nogales C. Co., owning the Cerro Prieto gold mines in Magdalena district, is arranging to build at Cerro Prieto a quartz mill with gas power machinery.

Reports from the Juanita placers, 65 kilometers south from Alamos, in Alamos district, shows progress. They are owned and operated by the Sonora G. M. Co., with main office in Mexico City. H. H. Greenleaf is manager. The property covers an area of 22 pertenencias and the gravel is said to run from 15 to 30 feet in depth and to average $1 per cubic yard. It is equipped with sluice boxes and centrifugal pump, the latter having capacity for handling 2000 cubic yards per day. Additional machinery is going in, says Superintendent R. D. Hughey.

The mill at the Constitution & Italia M. Co.'s camp in Magdalena district, will be completed and running next week, says Manager Magruder.

The Verde Reina M. Co. has heen organized to work the copper mines in the Verde Grande region, northwest from Hermosillo. R. Valenzuela of Hermosillo is principal owner and manager. Development work is in progress.

R. V. Daniels of Cananea, of the Arizona M. & Dev. Co., says work will be increased on the Gold Treasure mine, in the San Jose mountains near Naco, owned by the company. The Gold Treasure mine has a blanket ledge of gold-bearing quartz 3 feet wide assaying $15. A 20-stamp mill will he built. The materials are on the ground, with the boilers and engine. The power plant will be large enough to furnish power for more stamps, which will be added as the production of ore demands. The Gold Treasure is near the Cananea railroad and a siding will be laid to the mine. The ore from the mine will be taken down the mountain side on a tramway.

Layne & Clark of Cananea, owners of the San Miguel mine, are preparing to further develop the property and place machinery. The mine has 250 feet of tunnels and shafts. A quantity of ore is on the dump at the mine, which will he shippod.

Tepic.

There are two companies operating in the mineralized section of La Yesca. The section is a two and a half days' ride from the railroad.——The Zapopan G. M. Co. has started work again and has good roads between its mines and mills. Tunnel and general work on the Zapopan mine is under way, and on the San Miguel the old tunnel has been cleared and track laid. The entire tunnel will he cleared hy March 10.——The Compania Minera de Buena Vista is working the Buena Vista mine and reports taking out $75,000 per month.

Obituary.

R. J. McCARTNEY, superintendent of the Silver Lake mill, near Silverton, Colo.

GEO. W. SANDERS, formerly connected with the Vulture mine, died at Phœnix, Ariz., on the 5th inst.

THOS. WREN, an old-time pioneer miner of Nevada, died at Reno, Nev., on the 7th inst., aged 80 years.

A. W. KENZIE, a noted metallurgist and chemist and a prominent pioneer in metallurgical advance, died at Braddock, Pa., on the 13th inst., in the 84th year of his age.

W. A. HAMILL, a pioneer mining operator of Colorado and formerly part owner in the Pelican-Dives and the Terrihle mines in Clear Creek county, died on the 3rd inst. at Denver, Colo. Deceased was a veteran of the Civil War, and was a brigadior general in the National Guard of Colorado.

W. GUNDRY, for the last twenty-five years engaged in mining operations in the Tintic district, Utah, died on the 9th inst., at Salt Lake City, Utah, aged 58 years. Deceased came to the United States when 17 years of age, and became a miner at the Calumet & Hecla mine, Michigan. In 1875 he removed to Utah and became interested in mines in the Cottonwood district, Salt Lake county, subsequently removing to Silver City.

ALVINZA HAYWARD, a pioneer mine owner and operator of California and on the Comstock lode, Nevada, died at San Francisco, Cal., on the 14th inst. Deceased was born in Vermont, February, 1822. He was interested in the Eureka, (Amador Con.) and the Plymouth Con. mines in Amador county and the Springfield mine in El Dorado county, Cal. With C. D. Lane he was part owner of the Utica group of mines at Angels, Cal., and of the

Con. Eureka (Deadhorse) miue, Tuolumne county, Cal. On the Comstock, Nevada, he was interested in the Hale & Norcross and the Crown Point mines.

Personal.

F. L. BOSQUI is examining property at Goldfield, Nev.

L. D. GODSHALL, of Denver, Colo., is in Arizona on mining business.

H. DYATT has returned to Leadville, Colo., from a trip to Chicago, Ill.

J. B. FARISH of Denver, Colo., is in San Francisco, Cal., on mining business.

T. BARDEN is superintendent of the Ohio C. Co. mines at Bingham, Utah.

O. R. WHITAKER has returned to Denver, Colo., from San Juancito, Honduras.

R. G. DRINNAN is assistant manager of the Crow's Nest Pass Coal Co., at Fernie, B. C.

W. A. STEVENS, metallurgist with H. E. Wood & Co. of Denver, Colo., is iu the East.

CHAS. IRWIN succeeds Jos. Smith as manager of the Watseka mine, Rochester, Mont.

MANAGER CAITROW of the Ohio C. Co. at Bingham, Utah, is in Ohio on company husioess.

G. I. WRIGHT is managor of the Del Monte mine, at Railroad Flat, Calaveras couoty, Cal.

S. N. KNIGHT of Sutter Creek, Cal., is on a business visit to Portland, Or., and Seattle, Wash.

B. F. HARTLEY of Auburn, Cal., interested in Placer county mines, is in San Francisco, Cal.

W. F. DETERT, president af the Argonaut M. Co. at Jackson, Cal., is in San Francisco, Cal.

R. A. HAWKINS of Milford, Utah, interested in Beaver county mines, is in the East on business.

TODD C. WOODWARD has gone from Nova Scotia to Williams, Ariz., to the Anita Copper Co.

F. W. HOAR has resigned as superintendent of the Old Dominion C. M. & S. Co. at Globe, Ariz.

L. D. RICKETTS is general superiotendent of the Old Dominion C. M. & S. Co. at Globe, Ariz.

CURTIS M. LINDLEY, late of the University of California, is actively engaged at Kellogg, Idaho.

P. H. RAMSDEN, a mining engineer of Guanajuato, Mexico, is in New York City from Denver, Colo.

J. GLUYAS is superintendent of the Red Cross and Huron mines at Washington, Nevada county, Cal.

PHILIP ARGALL of Denver, Colo., has returned there from Mexico, where he has heen the past month.

R. J. CORY, manager Denver, Colo., branch Allis-Chalmers Co., has returned there from New York City.

G. W. WALLACE of Duluth, Minn., is manager of the Copper Butte mines near Florencc, Pinal county, Ariz.

G. J. BANCROFT has returned to Deover, Colo., from New York City, wl ere he has been on mining husiness.

A. COLVILLE is superintendent and mine manager at Coal Creek, B. C., for the Crow's Nest Pass Coal Co.

J. R. CARROLL of Hancock, Mich., is visiting mining properties io Utah and Idaho in which he is interested.

W. TOWNSLEY, JR., of the Grasselli Chemical Co., Cleveland, Ohio, made a trip to Denver, Colo., last week.

H. WHITBURN of Duluth, Minn., is superintendent of the Copper Butte group near Florence, Pinal county, Ariz.

H. Z. OSBORNE of Los Angeles, Cal., manager of the Dorleska mine in Trinity county, Cal., is in San Francisco, Cal.

G. G. S. LINDSEY is managing director of the Crow's Nest Pass Coal Co., operating at Fernie, Michel and Morrissey, B. C.

J. J. OTT, the veteran assayer of Nevada City, Cal., 77 years old, will celebrate his 19th birthday on the 29th inst.

Q. A. WHITE, a mill man from the Resurrection mine, Leadville, Colo., is now with the Akron mines, White Piue, Colo.

J. H. TALBOT, maoager of the Reina del Oro M. Co. at El Tiro, Sonora, Mexico, returned thore last week from Nogalos, Ariz.

W. A. FARISH, of Salt Lake City, Utah, former manager the Majestic M. & S. Co., is examining mines in Sonora, Mexico.

O. A. TIBBETTS has resigoed as manager of the Ohio C. Co., operating at Bingham, Utah, due to press of personal husiness.

A. C. BATES, of the Gutta Percha Ruhher & Manufacturing Co., returned to San Francisco, Cal., this week from a trip to New York.

D. H. JACKSON goes from Placerville, Cal., to Tonopah, Nev., March 1 to hogin sinking. He returns to Placerville, thence to Philadelphia, Pa.

G. A. BADGETT of Tonopah, Nev., superintendent of the Montana-Tonopah M. Co., is examining mining properties io San Diego county, Cal.

S. C. MYERS, representing G. W. Myers of San Francisco, Cal., for the Chrome Steol Works, Brooklyn, N. Y., is visiting the mines of Calaveras county, Cal.

H. C. BOSWORTH, manager of the Denver Fire Clay Co., Denver, Colo., is making a trip through Arizona aud Sonora, Mexico, in interest of his company.

C. O'KEEFE of Nogales, Ariz., president and maoager of the Sooora M. & M. Co., operating at Tubutama, Sonora, Mexico, has returned from a trip to New York.

H. KNUTSEN of Kalgoorlie, Western Australia, is in Colorado, making observations on the processes used in milling in that State, especially the cyanide process.

E. HOFFMAN, recently superintendent of the Indianapolis M. Co. in Tooele county, Utah, is superintendent of the Silver Shield Co. mioes at Bingham, Utah.

H. C. WEBER, superintendent of the Weber Gas & Gasoline Engine Co., Kansas City, Mo., is visiting the principal mining camps of Sonora, Mexico, on business.

G. A. OVERSTROM has returned to Chicago, Ill., from Craigmout, Ontario, where ho had been superintending erection of a plaot for the Canada Corundum Co.

C. W. PURINGTON of Doveton & Purington, mining engineers, Denver, Colo., has returned there from Cananea, Sonora, Mexico, where he has heen since Octoher last.

B. BALLANTYNE, for two years with the Golconda M. Co., near Sumpter, Or., has resigned as master mechanic and electrician, and will devote his time to his own interests.

G. CHARTERS, manager of the San Ricardo mine at San Ricardo, near Magdalena, Sonora, Mexico, returned to camp last week from a several week's visit in Canton, Ohio.

JOHN MCGEORGE of the Wellman-Seaver-Morgan Co. resigns March 1st, after which he will be at 501 Citizens buildiog, Cleveland, Ohio, having opened ao engineering office.

JNO. HOWELL, late general manager of the Broken Hill Proprietary mine, Australia, is io San Francisco, Cal., and contemplates an extended visit to the St. Louis Exposition.

W. B. ROBERTS has sold his Los Angeles, Cal., assay and chemical laboratory to the H. K. Wheeler Co. Mine examinations in Mexico will keep him in that country for the next few months.

SUPERINTENDENT GILBERT AND FOREMAN WILEY of the Ladd Metals Co. mines near Mineral, Washington county, Idaho, have heon appointed manager and superintendent, respectively.

F. P. SWINDLER, former superintendeut of the mines and mill at De Lamar, Nev., has returned there, vice F. Keith, resigned, who has acceptod a position at Salt Lake City, Utah, with J. H. Hammond.

MANAGER C. W. CLARK of the United Verde C. Co., at Jerome, Ariz., is in the Bermudas with W. A. Clark of Butte, Moot., principal owner of the United Verde. He will return to Jerome next month.

J. N. ESSELSTYN, until recently manager of the Mountain View group, near Sumpter, Or., has heen appointed as consulting engineer for the properties heing operated by the Geisor-Hendryx Co. in Sumpter district.

P. P. BUSH, general Western manager of the Vulcan Crucible Steel Co. of Aliquippa and Pittsburg, Pa., whose headquarters is in Denver, Colo., is in San Francisco, Cal., on his way to Portland, Or., and Spokane, Wash.

THE Western Society of Eugiueers, 1734-41 Monadnock block, Chicago, Ill., have elected the following officers: H. W. Parkhurst, president, 1. C. R. R., No. 1 Park Row; C. W. Hotchkiss, first vice-president, room 401 La Salle street station; W. L. Ahhott, second vice-president, Chicago Edison Co., 139 Adams street; Prof. W. D. Pence, third vice-president, Purdue University, Lafayette, Ind.; Andrews Allen, treasurer, room 1127, Monadnock block.

Commercial Paragraphs.

"Territory Embraced hy the Machinery Sales and Engineering Business of Chas. C. Moore & Co.," is the legend emhlazoned on a colored map of the western part of the North American Continent washed hy the waters of the Pacific from where the plaiotain leaves at Guadalajara, Mexico, rustle in the tropic hreeze to where the free American of Alaskan descent hathes his harharian hrow in the surf that thunders on the shore of far Attou. The idea is a clover one.

THE St. Louis Repuhlic of Jan. 29 gives the decision of the U. S. District Court io what was known there as "the colored strand trademark suit," which is of general interest. A St. Louis manufacturing house sought to restrain a competitor from using a trademark for thoir make of ropes, which, it was chargod, was an infringement on that adopted by the complainants. Their description of its trademark was as follows: "The trademark consists of a red or other distinctively colored streak applied to or woven in a wire rope. The color of the streak may be varied at will, so long as it is distinctive from the color of the body of the rope." In its decision the court held that this streak of color applied to or woven in the rope does not constitute a legal trademark, thus sustaining the demurrer to the hill seeking to enjoin the defendant from infringing on a registered trademark. Should this decision stand, it may occasion considerahle change in trademarks in other lines of business.

Trade Treatises.

1904 Catalogue No. 45 B., from Fairbanks-Morse & Co., Chicago, Denver and San Fraocisco, is devoted to hoists and hoisting machinery operated hy gasoline, naphtha, distillate, kerosene or crude oil.

New Patents.

DEWEY, STRONG & CO.'S SCIENTIFIC PRESS PATENT AGENCY, 330 Market St., S. F., bas official reports of tbe following U. S. patents issued to Pacific Coast inventors:

FOR TBE WEEK ENDING FEBRUARY 9, 1904.

751,975.—JAR CLOSURE—W. E. Brown, Los Angeles, Cal.
751,610.—HOOK AND EYE.—E. A. Campbell, Los Angeles, Cal.
751,613.—LIFTING JACK—R. F. Cook, S. F.
751,836.—ROLLER—W. E. Cumback, S. F.
751,901.—BRIDLE BIT—H. A. Cummings, Del Paso, Cal.
751,722.—NOZZLE—W. A. Dohle, S. F.
751,848.—PLUG TOBACCO PULLER—J. Goldsmitb, Eugene, Or.
751,791.—METAL GRINDER—J. H. Haskins, San Diego, Cal.
751,926.—LOCOMOTIVE ALARM—C. D. King, Olympia, Wash.
751,659.—WBETSTONE CASE—D. F. Larkin, S. F.
751,560.—MOTOR VEHICLE.—C. E. Larrahee, S. F.
751,661.—GATE HINGE—J. Leffler, La Grange, Cal.
751,863.—CLOTHES DRIER—F. S. MacDougall, Seattle, Wash.
751,532.—ROCK BREAKER—W. A. Merralls, S. F.
751,668.—DOOR VENTILATOR AND SCREEN—J. H. Moskow, S. F.
751,676.—FRUIT ELEVATOR—C. D. Nelson, Lordsburg, Cal.
751,678.—WBEEL BRAKE—H. Neusser, San Rafael, Cal.
751,751.—EXPLOSIVE—B. D. Pike, S. F.
751,694.—ROTARY ENGINE—J. E. Shearer, S. F.
751,758.—PUMP PISTON—R. E. Small, Los Angeles, Cal.
751,457.—CATTLE GUARD—J. Sneider, Buckley, Wash.
751,818.—SOUND INTENSIFIER—G. T. Swenson, San Pedro, Cal.
36,788.—DESIGN—M. Alves, West Berkeley, Cal.
36,782.—DESIGN—C. W. Robinson, San Diego, Cal.

Notices of Recent Patents.

Among the patents recently obtained through Dewey, Strong & Co.'s SCIENTIFIC PRESS U. S. and Foreign Patent Agency, tbe following are worthy of special mention:

GATE HINGE.—No. 751,661. Feh. 9, 1904. John Leffler, Lagrange, Cal. The object of this invention is to provide a hinge of simple construction whicb may be attached to the right or left of a post to allow the gate to swing in one direction or the other.

MOTOR PROPELLED VEHICLE.—No. 751,660. Feh. 9, 1904. C. E. Larrabee, San Francisco, Cal. Assigned to Larrabee Automobile & Mfg. Co., a corporation. This invention relates to improved mechanism with self-propelled vehicles; and it consists in the combination, witb suitable engines or motors, of crank shafts, connecting rods and levers having short and long arms and toothed segments and racks with intermediate gears through which power is transmitted to the propelling wheels of the vehicle.

COMBINED SCREEN, WINDOW, AND VENTILATOR ATTACBMENT FOR DOORS.—No. 751,668. Feb. 9, 1904. J. H. Moskow, San Francisco, Cal. This device contemplates the doing away of the cumhrous, unsightly separate screen door and the substitution for the usual glass panel of tbe outer door of a hinged screen normally closing the opening and allowing ventilation, a hinged sash adapted on occasion to he closed over the screen, and so afford a door secure against tbe cold or the elements, and means co-operating with the sash when open to keep the door in normally closed position.

Latest Market Reports.

SAN FRANCISCO, February 19, 1904.

METALS.

SILVER.—Per oz., Troy: London, 27½d (standard ounce, 925 fine); New York, har silver, 59½c, refined (1000 fine); San Francisco, 59½c; Mexican dollars, 47@48c Sao Francisco, 46½c New York.

Silver has made a decided advance the past week, going to 59½ cents, the present quotation. To just what cause this increase in price is due is not apparent, but the fact that an advance has been made must he satisfactory to tho miners of the metal.

COPPER. — New York: Standard, $12.50; Lake, 1 to 3 casks, $12.50; Electrolytic, 1 to 3 casks, $12.37½; Casting, 1 to 3 casks, $12.37½; San Francisco: $15.00. Mill coppor plates, $17.00; hars, 18@24c. London: £57 2s 6d spot per ton.

Copper remains unchanged from last week's quotations for Lake, with electrolytic and casting a fraction higher. Heavy shipments of copper have heen made to Europe, reaching in January ahout 25,000 tons. It is thought Februrary shipments will not exceed 12,000 tons.

LEAD.—New York, $4.60; Salt Lake City, $3.50; St. Louis, $4.25 San Francisco, $4.50, carload lots; 4⅛c 1000 to 4000 lbs.; pipe 6½, sheet 7, har 5¾c; pig, $4.85. London: £11 12s 6d ℔ long ton.

SPELTER.—New York, $5.10; St. Louis, $5.00; London, £21 12s 6d ℔ ton; San Francisco, ton lots, 6¾c; 100-lb. lots, 7c.

TIN.—New York, pig, $28.37½@28.75; San Francisco, ton lots, 30½c; 500 lbs., 31c; 200 lbs., 31½c; less, 32½c; har tiu, ℔ lb., 35@37½c. London, £125 10s spot.

PLATINUM. — San Francisco, crude, $18.00 ℔ oz.; New York, ingot, $19.00 ℔ Troy oz. Platinum ware, 75 @ 82c ℔ gram.

QUICKSILVER. — New York, $46.50@47.00, large lots; London, £8 7s 6d; San Francisco, local, $44@45 ℔ flask of 76½ lbs.; Denver, $48.00. Export, $42.00@42.50.

BABBITT METAL.—San Francisco, No. 1, 10c; No. 2, 7c; No. 3, 6½c; extra, 17½c; genuine, 31½c; Eclipse, 35c.

SOLDER. — Half-and-half, 100-lb. lots, 19.50c; San Francisco, Plumhers', 100-lb. lots, 16.50c.

ZINC.—Metallic, chemically pure, ℔ lb., 50c; dust, ℔ lb., 10c; sulphate, ℔ lb., .04c.

NICKEL.—New York, 50@60c ℔ lb.; too lots, 40@47c.

ALUMINUM.—New York, No. 1, 99% pure ingots, 35c; No. 2, 90%, 30@34c.

LUMBER. — (Retail): Pine, ordinary sizes, $24.00@25.00; extra sizes higher; redwood, $28.00@30.00; lath, 4 feot, $4.50 @5.00; pickets, $21.00; shingles, $2.50 for No. 1 and $2.25 for No. 2; shakes, $13.50 for split and $15.00 for sawed; rustic, $28.00 @35.00.

NAILS.—This week the basic prices aro: Wire, $2.77; Cut, $3.25. Meanwhile the nominal quotations per keg (list prices) are: No. 20d to 60d, Wire, $3.35; Cut, $3.55; 10d to 16d, Wire, $3.45; Cut, $3.35; 8d Wire, $3.50; Cut, $3.50; 6d and 7d, Wire, $3.60; Cut, $3.60; 4 and 5d, Wire, $3.70; Cut, $3.70; 3d, Wire, $3.85; Cut, $3.85; 2d, Wire, $4.10; Cut, $4.10. Special rates for carload lots.

LIME.—Santa Cruz, $1.25 country, $1.25 city ℔ bbl.

CEMENT.—Imported, $2.15@2.40 ℔ hhl.; California carload lots, $2.00 f. o. b. at works; small lots, $2.25 ℔ bbl. in sacks, 4 sacks to bbl.

STRUCTURAL MATERIALS.

IRON.—Pittsburg, Bessemer pig, $13.60 @13.85; gray forge, $12.60; San Francisco, har, 3c ℔ lb., 3½c in small quantities.

STEEL.—Bessemer hillets, Pittshurg, $23.00@23.00; open hearth hillets, $23.00 @23.00; San Francisco, har, 7c to 12c ℔ lb.

URANIUM.—Oxide, ₱ lb., $3.50.

(These prices are wholesale, f. o. b. San Francisco, unless otberwiso noted.)

SITUATIONS WANTED.

AN EXPERIENCED AMALGAMATOR AND all around mill man desires position in mill; 15 years' actual practical experience; understands amalgamation, concentration and assaying; competent to take full charge or will accept subordinate position with good wages. Good reference. Address Mill Man, Mining and Scientific Press.

ASSAYER AND METALLURGIST WITH OUTfit wishes position. Address "L.", this office.

ATTENTION OF MINING OPERATORS REQUESTED.

An experienced Physician, Chemist and Druggist desires to locate with his family in a Western mining camp or district. A regular salaried position preferred; ample references to be exchanged. Address Dr Paul Traub, Bordentown, New Jersey.

EXPERIENCED DRAUGHTSMAN AND DEsigner wants position with company building or operating gold dredges. Adr. "Dredge," this office.

EXPERIENCED SUPERINTENDENT, ENGIneer, Metallurgist; technically and liberally educated; 15 years handling men and machinery of smelters, mills and mines. See testimonials. Address Prof. Stickney, Mountain View, Cal.

GRADUATE CIVIL ENGINEER, OPEN FOR engagement; 14 years experience; A1 draughtsman. Address "Cappella," this office.

MILL AND SMELTER SUPERINTENDENT, at present disengaged, wishes similar position with responsible company; college graduate with varied experience. Best of credentials furnished and required. Address "Gluckauf," care this office

MINING ENGINEER WITH EXTENSIVE EXperience in coal and placer mining desires position. Address "Lulu," this office.

MINING ENGINEER, WITH LARGE PACIFIC Coast experience, desires charge of a mine; understands milling, concentration, chlorination, cyanidation; or will act as consulting engineer. Address "Pacific," this office.

NORWEGIAN GRADUATE ENGINEER would like position with land company. Can take charge of work in field or office. Ten years experience. Address "Norway," this office.

PRACTICAL HYDRAULIC MINER OF EXPErience wants place with good company as foreman or superintendent. Can do any kind of work in hydraulic mine. Address L. P. S., care of Mining and Scientific Press.

WANTED, POSITION AS SUPERINTENDENT of hydraulic mine; have had 30 years' experience in all kinds of hydraulic or placer mining, and can furnish the best of reference. Address Box 14, this office.

WANTED—POSITION WITH MINING COMpany as manager or assistant. Examinations, surveying, assaying; also familiar with drift and hydraulic mining. Best of references. Address W. H. J., this office.

WANTED, LOCATION FOR CUSTOM QUARTZ mill. Address J. B. Harrell, 1056 South Gaylord St., Denver, Colo.

PATENTS

Our U. S. and Foreign Patent Agency presents many and important advantagee as a Home Agency over all others, by reason of long establishment, great experience, our Washington branch which tende *exclusively* to our business before the Patent Office, intimate acquaintance with the subjects of inventione in our own community, and our most extensive reference library, containing official American reports since 1790, with full copies of U. S. Patents since 1872. All worthy Inventions patented through DEWEY, STRONG & CO.'s Patent Agency will have the benefit of a description in the *Mining and Scientific Press*. We transact every branch of patent business, and obtain patents in all countries which grant protection to inventors. The large majority of U. S. and foreign patents issued to inventors on the Pacific Coast have been obtained through our agency. We are conservative and counsel preliminary examinatione in cases of doubtful novelty. Guide to inventors sent on request.

A Rig Like This

DON'T COST MUCH. It will hoist all the rock that can be broken in the first 250 or 300 feet of shafts and drifts; if you strike more ore in that distance than this rig can hoist you can afford to throw it away. If you don't strike any ore, it will be a good thing you did not put on a steam hoist. Better develop a mine than try to develop a fine shaft house, hoist, etc.—you can get them later. We would like to send you a catalog but can't do it because we don't

An Oregon Gold Mine.

In Grant county, Oregon, are a number of valuable and promising gold properties, among them being the Badger mine, near Susanville, on Elk creek, a small tributary of John Day river, and about 30 miles west of Sumpter in an air line, but about 55 miles by wagon road. A dark gray clay slate is the most important rock formation of the district. This formation strikes N. 70, E., with a dip of 65° to the south. There are numerous small dikes of aplite cutting the slates. Serpeutine, gabbro and diabase are also found in the vicinity. On the main range near the head of Elk creek, on the summit of the Blue mountains, the granite is exposed. The placers of Elk creek undoubtedly derived their gold from the quartz veins of the vicinity. In 1869 a pan mill was built on the Monumental vein to work the ores of that mine. There are numerous free gold prospects scattered about the district, but the principal values are in heavy sulphide ores containing comparatively little free gold. The Badger vein was discovered in 1869, when it was known as the McQuade vein. Considerable free gold was obtained by milling the decomposed croppings, this ore averaging $25 per ton in arrastras. Later a 10-stamp mill was built, but the ore does not readily yield its values to ordinary gold milling processes, and the high grade ore is sorted out and shipped to the smelters, the remaining lower grade material being crushed in a concentrating mill, built after the 10-stamp mill was found unsuitable, concentrated and the concentrates shipped. The accompanying engraving illustrates the company teams loading these high-grade ores for shipment to the railroad and smelter. The mine is 2½ miles northeast of Susauville, at about 4300 feet altitude. The vein is a fissure, the accompanying slate walls being seamed with numerous quartz seams, which are perpendicular to the schistose structure of the rocks. The first-class ore consists of a massive irregular mixture of sulphides, pyrite, arsenopyrite, zincblende, with a little galena, chalcopyrite and tetrahedrite (gray copper). Ore containing this latter mineral is usually rich in silver and also carries considerable value in gold. Shipping ore always contains galena.

Loading Concentrates at the Badger Mine, Oregon.

Overcapitalization of Mining Companies.

Oue of the most objectionable features of new mining companies, and also one of the most serious obstacles in placing stock of such concerns, is overcapitalization. The average promoter is not a miner, nor is he always the shrewd, experienced business man he would have the public believe, for if he were either a miner or a business man he would see the uselessness—the folly—of greatly excessive capitalization. Ordinarily shares in new concerns are offered at a price far below par, and evidently the intention is to make the shares look reasonable in price as compared with the par value, while the natural inference is that the investment must accordingly be a good one. A compauy organizes with one million shares having a par value of $10 each, representing $10,000,000. Then a "limited amount" of stock is offered at 50 cents per share—only 5% of the par value, with a threat to raise the price to $1 at an early date. Those seeking investment can see a profit of 100% at least, if they buy promptly, and take a block of shares at 50 cents, in the belief that at the date fixed by the company for advancing the price of shares their shares will also advance and will theu be worth at least twice what is paid for them. As a matter of fact, capitalization bears no relation to actual value of the mine whatever. There are scores of mines, both good and bad, which abundantly prove this. A notable instance is that of the Calumet & Hecla, incorporated for $2,500,000, of which only $1,200,000 has been paid in. The mine has paid $85,000,000. Other mines capitalized at $10,000,000 have never paid a dividend and never will. Another fallacy is the practice of figuring the percentage on capital stock or market value of dividends paid. A mine may be able to pay from $50,000 to $200,000 per month and ou the strength of this the stock may go to $50 or over per share, representing an actual value of $10,000,000. After a few months the dividends suddenly cease and the stock falls so rapidly that the holders are unable to sell at any price. There are numerous instances of this kind. The best and most satisfactory way to promote a new mining scheme is first to secure a good mine, capitalize it at a good figure, and place the stock at a price commensurate with the present value of the mine.

AN effort is being made in Congress by Representatives from New Mexico to throw open to location the mineral veins and deposits on land grants in that Territory. This is by no means a new step in this matter, as it has been a subject of contention between prospectors and the owners of grants in the Southwest for many years, and without satisfactory result—at least, not to the miner. When this subject was introduced in the House of Representatives of the Fifty-seventh Congress, a bill was framed which in effect, in part, provided as follows: That thereafter all gold, silver and quicksilver deposits, or mines, or minerals of the same, on lands embraced within any land claim confirmed by the decree of the court of private land claims, or as to which a suit may be pending in any court having jurisdiction thereof, are hereby declared to be free and open to exploration and purchase, under the mining laws of the United States, the local mining laws and regulations in addition thereto and consistent therewith as may be prescribed by the Secretary of the Interior from time to time, by citizens of the United States and those who have declared their intention to become such. The Committee on Mines and Mining sought the views of the Secretary of the Interior upon the measure, and Secretary Hitchcock replied that it was the opinion of the Department that only such deposits and veins of minerals as were known to exist prior to the confirmation of the grants were applicable to the intended legislation. It is evident from the above, which is only a brief extract from a lengthy opinion, that no rights under the general mining laws, in the opinion of the Land Department, can be acquired on Mexican grants where the title has been confirmed by the Government. There are certain possible exceptions where the grant claim is finally rejected by the United States; or in cases where an excess has been claimed and the surplus resorts to the public domain, or where grants fall within the jurisdiction of the court of private land claims.

Gross vs. Net Value of a Mine.

The process of properly sampling and valuing a mine is one involving an amount of labor and responsibility on the part of the engineer, or other person making the estimate, which is proportional to the development of the mine and the value involved. As mines may be bought, though possibly not being offered in the market, there are two sides to the question of the value of a property—the owner and the buyer. Each side may be represented by one or several persons, or each side may be a corporate company. In any case the position of either side is essentially similar. The owner, or his engineer, blocks out the mine, samples every accessible portion of it, and all samples are assayed. The result, comprising the number of feet or inches in width of each sample taken, and the value obtained by assay of each sample, is plotted on a mine map. Each block of ore, with its several samples, widths and values, is figured separately, and from this data the value of the mine, as represented by the sum of all the blocks, is calculated. This is the gross value, and if the work of measurement, sampling and assaying has been carefully done, valuable information has been secured, upon which the owner may fix his own idea of the net valuation of his property. There are many instances where the owner and prospective buyer may, and do, readily arrive at the gross valuation of a mine—actual, probable and possible—but the harmonizing of the ideas of net value is often a difficult and sometimes an impossible thing. The owner naturally figures as closely as he can on expenses and investment, and arrives at figures representing the net value of the property from his point of view, but which figures are greatly at variance with those of the possible purchaser, who is not prone to underestimate. The owner may figure a stated amount for mining and reduction and deduct these from the gross assay value, and find a large net profit in the property.

The would-be buyer may or may not be willing to accept the figures of the seller as to working costs—presuming that they have already agreed upon the gross value. The buyer argues that it is improbable that the ore can be worked closer than 90% of its assay value, and it may not yield this much. He also figures that the getting of the metal (base or otherwise) to market or mint will cost something. He estimates the cost of equipment, if the mine is not already equipped, or extensions and necessary changes in plant, and also adds an interest charge to capital invested, all of which may have been omitted or overlooked by the seller. The buyer figures for net results, the seller for all he can get, and, owing to these conflicting views, many sales, after expensive investigation and long-continued negotiation, fail and are never consummated. A favorite argument of the seller is "the mine has produced so many thousands, or millions," as the case may be, when in reality this is a poor argument for the seller, as the mine can never reproduce those millions, though other millions may still remain. In the earlier years of mining in the West investors took desperate chances, and large fortunes were lost in consequence, though here and there were exceptions so notable as to prove a strong incentive to others to venture. In days of excitement mining deals are easy of accomplishment; but when the days of adversity come, as they always do where extravagance and unsuitable methods have prevailed, these must give place to economy and scientific practice, and men then learn to judge the real merit of a mine and fancy prices fall. The investigation and valuation of mining property has been reduced to a science, in which the element of common sense plays an important part. Nearly every factor in the valuation of a developed mine can be arrived at with almost a certainty. Why, then, should there be a conflict of opinion as to the actual value of any mine? If this can be satisfactorily adjusted between the two sides to a deal, the prospective value may also be fixed in a way which should be satisfactory to both sides.

Owners commonly overrate not only the net but also the gross value of their property. A mine may possess large value when measured on a basis of tons in sight and values as determined by samples and still, while insuring a profit, be incapable of being worked on a scale commensurate with its magnitude, for various reasons—situation, climate, etc. In some European countries mines are in operation today which have been worked for a century, or possibly several centuries. In the Western United States similar mines would have been exhausted in less than fifty years. The element of time is important and the buyer includes this with other factors in determining the net value of a mine. The owner argues that the value is there and time is not a matter for important consideration. Often the expense of equipment is very large, and in view of the interest value of the money invested, it is business to get the mine in a producing stage as quickly as possible and to work the mine out as fast as is expedient with due regard to the lives of men employed and the proper working of the mine. It is improbable that all of these differences of opinion will soon be harmonized, but where it is so readily possible to determine the most of the elements involved, there should no longer exist greatly varying ideas of the value of a mine.

MINING COMMISSIONER WHITE of Colorado will undertake to compel mines in that State not already equipped with the necessary safety devices in shafts to put them in. A legal technicality has arisen as to the authority of the Commissioner to enforce his orders. There are laws in Colorado providing for safety devices for cages and skips, but none for an overwinding device on mine cable. What particular usefulness any sort of device "on the cable" can have is difficult to understand. The crosshead or draw bar of a cage or skip is an obstruction which shows what happens when the engine overwinds. Either the cable must part (which it usually does under such circumstances) or the top of the head frame is torn to pieces. The latter rarely occurs, though more or less damage to the upper portion of the frame usually results in a case of overwinding. The proper sort of device is one which will prevent the skip from falling down the shaft in the event the cable breaks. This placed at the proper point in the head frame will insure the cage or skip remaining stationary after the rope breaks in a case of overwinding, but in all other parts of the shaft the only hope for safety lies in clutches which shall grip the guides so firmly that there is no likelihood of the cage going down unless the guides be torn to pieces, and to guard against this latter contingency the guides should be made of timber of such size and strength as to make their destruction in this way impossible.

THE injunction granted plaintiffs against the Amalgamated Copper Company by Judge Clancy at Butte, Mont., some time since, and which tied up about $3,000,000 set aside for the payment of dividends by that company, is no longer operative. The Supreme Court of Montana on the 1st inst. dissolved the injunction, and as the plaintiffs' attorneys did not make application for a rehearing it is probable that the lower court will be asked to dissolve the injunction in accordance with the Supreme Court decision. This injunction arose over the decision that the Amalgamated Company, not being a Montana corporation, had no right to hold the stock of another corporation and to vote the same. The court, in keeping with this decision, restrained the Amalgamated Company from disbursing the accumulated dividends.

IT is an easy matter for a mining engineer or a geologist to be led into error by too superficial examination or by forming a too hasty conclusion, in the investigation of a mine or in studying a mineral zone or formation. One may be cautious and slow to arrive at conclusions without being pessimistic. The average miner is optimistic, and he has small regard for those who do not share his exalted opinions as to the value of his mine, but to the trained and experienced mine examiner facts must be available upon which to base conclusions. Indications are given their full value; but something more tangible and positive than indications, or proximity to good values on adjoining property owned by some one else, are essential to a favorable report. It is nearly as bad to make a mistake through ultra-conservatism as it is to err by being over-sanguine and visionary as to unseen values.

CONCENTRATES.

In determining the value of assessment work done on a mining claim in the State of Nevada, $4 is fixed as the value of a day's work.

✤✤✤✤

Ores containing molybdenite yield better results if crushed with rolls than with stamps, as with the former the tendency to slime is greatly lessened.

✤✤✤✤

Mine water of copper mines frequently contains sufficient value in copper in solution to justify passing the water over scrap iron to precipitate the copper. Tin scrap, if obtainable, is generally used for this purpose.

✤✤✤✤

Where copper sulphide occurs disseminated in schist, ore of this kind is usually easy to concentrate. The value of the concentrated ore will depend upon the amount of iron sulphide present, and also upon the completeness of concentration.

✤✤✤✤

In concentration by water all particles of the same, or approximately the same specific gravity, do not settle in the same box or other receptacle. Scaly minerals will be carried along by the current when granular minerals of the same specific gravity settle.

✤✤✤✤

A hoisting cable 2 inches in diameter and 3000 feet long will weigh 18,900 pounds. To this is usually attached a cage or skip weighing from 4000 to 5000 pounds and a load of 8000 to 12,000 pounds, a maximum of 35,900 pounds. This is raised at various shafts at speeds ranging from 1000 to 6000 feet per minute.

✤✤✤✤

It is not customary or the best practice to roast sulphide ores before concentration. Such ores concentrate better without roasting. The values in some gold ores containing substances which interfere with amalgamation, such as graphite, molybdenum, etc., will yield a good percentage of their value by concentration.

✤✤✤✤

A convenient way of testing for heavy spar (barite) is to heat the pulverized mineral with sodium carbonate on charcoal before the blowpipe. Place the fused mass on a surface of clean silver (coin) and add a drop of water. If sulphur be present, a black or yellow stain of silver sulphide will be formed on the surface of the silver.

✤✤✤✤

Steam turned into a shaft where blasts have just been fired will quickly dispel powder smoke and gas, if introduced near the bottom of the shaft. Where steam sinking pumps are in use this is a convenient means of quickly getting rid of smoke, but it is also bad for timbers, causing them to rot much more quickly than they otherwise would.

✤✤✤✤

No chairs or other obstruction placed at the level of the floor at the collar of a shaft will afford safety to men in a case of overwinding where the head frame is high. It may save men from being dropped to the bottom of a deep shaft, but a fall in a cage a distance of 50 or 60 feet is sufficient to seriously injure if not kill any one who may be on the cage.

✤✤✤✤

Bismuth is comparatively rare, and occurs chiefly in metallic state. It has a reddish-white color and brilliant lustre. It is easily dissolved in nitric acid. The alloy known as "Wood's fusible metal," which melts at 60.5° C., is an alloy of bismuth 4 parts, lead 2 parts, cadmium 1 part and tin 1 part. This alloy expands upon cooling and solidifying, and is used in making casts.

✤✤✤✤

Sulphuric acid may be made at any mine where sulphide ores are roasted, but it is not considered profitable in view of the limited amount of acid required in most metallurgical operations, and of the comparatively small amount of ore treated. As sulphuric acid can be bought at two cents or less per pound it does not pay to manufacture the acid in the mountains and ship it to large commercial centers for distribution.

✤✤✤✤

The "serpentine" hook commonly called by miners "pigtail" hook, used for hoisting at prospect shafts where a windlass or whim is in use, has only the fact that it is convenient and quickly adjusted to recommend it. In lowering a bucket, should the bucket strike the timbers, the hook is likely to become detached, and it is looked upon by experienced miners as an unsafe device. One of the numerous "safety" hooks is far better.

✤✤✤✤

In order to avoid the operation of the mechanics' lien law in the State of Nevada, it is necessary that the owner, or a person having or claiming an interest in a mine, shall within three days after he shall have obtained knowledge of the construction, alteration or repairing, give notice that he will not be responsible for the same, by posting a notice to that effect in a conspicuous place on the land or building in question.

✤✤✤✤

The water supply for a stamp battery and that for concentrators should always come from a tank in which the water is kept at a constant level, in order that the flow of water to batteries or concentrators may not be variable. A constant level of water in the tank can be secured by arranging a float connecting by lever with a valve, which opens or closes as the water rises or falls, thus admitting more or less water to the tank as required.

✤✤✤✤

An improvement upon an already patented article may be patented, but the right of the improver does not extend beyond his improvement. He may not use the original article, neither may the original inventor use the improvement, without license. The rights of the two parties are reciprocal. A patent in the United States gives the patentee the exclusive right to manufacture, sell or use the invention throughout the entire territory under control of the United States. The sale or use in the United States of a patented article manufactured in a foreign country is just as much infringement as though the article were manufactured in the United States without authority from the patentee. The redress of the inventor for infringement of a patented article is by suit brought in the Federal Court, praying for an injunction and damages.

✤✤✤✤

The spitting of the lead "prill" when cupellation commences is unusual, and may be due to dampness of the cupel or to a sudden draught of air which causes the surface of the lead to suddenly contract, forcing the molten interior through the outer crust. Cupels should be placed in the muffle at the time of starting the fire, then they slowly heat without cracking, and have the temperature of the muffle when ready to place the prills in the cups. They should be marked and placed in position when first put in the muffle, so that they need not be disturbed, and the several prills placed in their respective cupels, and the furnace closed. When cupellation commences, the door of the muffle (usually a piece of fire brick) should be withdrawn slowly, so as not to cause a sudden rush of cold air into the muffle, as this may cause spitting of the lead and occasion loss.

✤✤✤✤

It is difficult if not impossible to estimate with even approximate accuracy the size of timbers required to hold any particular mass of rock in place in a mine, for the reason that it is impossible to know accurately the amount of weight or pressure the timbers may be required to stand. The jointing planes, unseen fissures and possible swelling of the ground by oxidation and absorption of air will exert pressures not wholly attributable to "dead weight," and in the absence of definite information the miner places timbers his experience has taught him should support the ground. Often the timbers are larger than were required, and in other instances timbers two or three times as large would be insufficient. In some instances timbers are seen falling into decay and dropping from their original position, while the rocks still stand with no sign of caving. In other cases heavy timbers placed in the mine are seen to be taking heavy weight within twenty-four hours, and in a month or less require reinforcement or renewal.

✤✤✤✤

Copper ore (chalcopyrite) often occurs in sedimentary rocks—limestone and quartzite and the slaty or schistose rocks adjoining the copper-bearing stratum, situated in the direction of drainage may become enriched with copper carbonates and oxides from the copper sulphate leached from the sulphides in the process of weathering. This would possibly result in the formation of a rich ore deposit in a rock which normally contain no copper. In such deposits as these the copper is not likely to descend a great distance from the surface. There are examples of this sort of deposit at several places in the Black Hills of South Dakota, on upper Rapid creek, near Castle creek, and on the mineral zone known as Blue Lead, near Sheridan. In the deposit on Rapid creek the surface of the black slate formation which adjoined the quartzite the ores were high grade (green carbonate and black oxide chiefly), but a flat vein of quartz intersected the slates a few feet below the surface and the copper values dropped from 20% to 40% above the vein to about 2% immediately below it. The quartz vein had acted as a dam to the copper solutions and the enrichment of the slates was confined to the superficial portions. The quartzite at the surface was barren of copper, only a siliceous limonite remaining. In depth a mixture of copper and iron sulphides were found, constituting the normal ore.

✤✤✤✤

Many of the mining districts of the southwest in Nevada, southern California and Arizona, which have dry mines near the surface in depth, develop water, and in several noted instances, as at Piocho, Nev., and Tombstone, Ariz., when water level was reached the quantity of water was very large, and at once became a source of great expense. Probably a shaft sunk in any portion of the desert region will reach water if continued deep enough. Water is usually found by sinking a well in dry lake basins, but this water is nearly always heavily charged with mineral salts, which to a great extent unfits it for boiler use, though it is generally found all right for amalgamation, probably due to the presence of alkalies in the water. The cost of pumping water at desert wells depends upon the depth from the surface of the ground to the water, the size of plant employed and kind of fuel used. Gas engines using distillate have been used to advantage for this purpose and may be recommended, as the load is not greatly variable. At Hedges, San Diego county, Cal., at a cost of $22 per day, 100,000 gallons of water were delivered daily through a pipe line from the Colorado river, a distance of 14 miles, the vertical lift being 500 feet. The fuel was driftwood, etc., gathered by Indians along the bank of the Colorado river. The pumps were operated by steam. A second pipe line was laid and double the quantity of water was pumped at only 60% increase in expense.

✤✤✤✤

The Whiting hoisting system was introduced by S. B. Whiting. It comprises a system of grooved wheels, like those in use at cable car power house stations. The rope passes several times around two drums, which are usually both driving drums. One end of the rope is attached to the hoisting cage or skip. The rope passes over the sheave, around the first drum or grooved wheel several times, then over an idler pulley, and thence over a third wheel to the sheave over the adjoining compartment of the shaft. The idler is used to adjust the position of the skips in relation to the several levels. This is accomplished by placing the idler on a movable carriage. The idler is usually in a horizontal or inclined position. When hoisting, the movable carriage is clamped to the track and is also held in position by a rope which is connected with a winding drum. The length of track required for this differential arrangement of the skips is one-half that required in the shaft. If it is necessary to adjust the position of the skips by 500 feet, the track must be 250 feet long. In order to overcome the constantly changing relation of weight of cable and skips when these are run in balance—that is, one moves down the shaft as the other is hoisted—the "tail" rope has been introduced. A rope is secured beneath the bottom of each skip, the rope passing around a sheave wheel at the bottom. This equalizes the weight of skips and cable at all points, and the engine has only the load of rock to hoist. The introduction of the tail rope system is claimed to have made hoisting from great depths more economical, but it has been applied to a limited extent in the Western United States, though of frequent application on the Rand. The tail rope system is applied where all hoisting is done from one level.

✤✤✤✤

The capacity of a blast furnace of given hearth area depends upon several important factors. Among these are distance between tuyeres; hot or cold blast; character of ore, amount of fuel used, blast pressure, and physical condition of ore (that is, whether coarse or fine), and the personal equation, represented by the smelter in charge, is a large one. The amount of water required by a water-jacketed furnace, cooled from hearth to throat, is variable and depends, says E. D. Peters, upon whether the ores smelted are of a nature to form a protective coating upon the walls of the shaft, and one which does not accumulate so rapidly as to require frequent barring for its removal; whether the coke used is kept supplied with all the ore it can possibly take care of, so that it may have no energy left to waste in heating the jacket; whether the coating substances accumulating on the inside of the furnace are good heat conductors or not; whether the ore is granular, or contains too large a proportion of fines, in which case it will be necessary to frequently allow the ore column to sink deep in the shaft, and thus expose the walls of the jacket to a powerful, though temporary, heat; upon the specific heat of the slag, and upon the pressure of the blast, and the skill of the general management of the furnace. The maximum amount of water required per hour for a furnace of 3 square feet hearth area when running normal and to its fullest capacity is 460 gallons; a furnace of 12.5 square feet hearth area requires 1300 gallons; one of 18 square feet, 1800 gallons; one of 30 square feet, 2000 gallons, and one of 36 square feet, 2200. When blowing in or out, the quantity of water required will be from two to three times the amounts above stated, as at such times the jacket is exposed to a much higher heat than usual and for a longer period.

✤✤✤✤

The amount of water required for the successful operation of a concentrating mill varies greatly. If the ore be mostly silica, much less is required than if it be clayey. The character of the mineral to be concentrated is also important in determining the amount of water to be used. In the Lake Superior mills, where native copper is concentrated, a very large amount of water per ton is used. At Butte, Mont., where copper and iron sulphides are concentrated from siliceous ores, much less is required. In concentrating copper-silver ores at the Gagnon mine at Butte, 5000 gallons of water were used per ton of ore. This was with steam (Ball) stamps. Where gravity stamps were used in concentrating Butte ores 3000 gallons were found sufficient. At the Colorado concentrator in Butte, with a capacity of 300 tons per twenty-four hours, 600 gallons of water were used per minute, or about 2700 gallons per ton of ore treated. In a gold mill, where amalgamation followed by concentration is practiced, the amount of water used is much less than where concentration of copper ore is in progress. Ordinarily, 1000 to 1200 gallons of water are sufficient for battery and plate amalgamation, but it is good practice to use as little as possible to do the best amalgamating and keep the mortars and plates clear. When the pulp from the plates goes to the vanners clear water is added to the concentrating machine. This amount is varied with the various characters of ores treated, or with the changes which may occur from day to day in ore from the same mine, where ore from one part of the mine or from some particular vein is more highly sulphuretted than other portions. Where water is scarce, it may be conducted from the mill to the settling reservoir and the clear water pumped back and reused. The loss seldom exceeds 50%, and where proper arrangements are made should not reach that amount.

The Hendryx Electro-Cyanide Process.

Written for the MINING AND SCIENTIFIC PRESS by C. M. FASSETT.

In Republic, Wash., are three idle cyanide mills, all built by men of large experience in this branch of metallurgy, and with an outlay in the neighborhood of $750,000. The mills are models in their design, and the character of the machinery and appliances for thorough and economical work, but they are idle. There are thousands of tons of good milling ore broken and blocked out in the mines along the main belt, yet the mills are idle. The district is paying no dividends. The mine which has shipped the best ore and upon which the most expensive mill has been built is about to be sold, with all its improvements, to satisfy a mortgage loan of less than $100,000. Some of the mines are now shipping ore to the British Columbia smelters, and although they are getting a very low freight and treatment rate, considering the highly siliceous character of their ores, it is hard to figure a profit on anything that assays less than $10 per ton, and the value of the bulk of their ore is less than that figure.

No wonder times are dull in Republic.

Now comes W. A. Hendryx of Los Angeles, Cal., who says he has a process by which these ores can be worked up to 80% of their assay value in gold and silver, at a cost not exceeding $1.50 per ton, and with machinery inexpensive to install and well adapted to be added to crushing mills now in existence. After considerable experimenting on charges of 100 to 200 pounds of ore in a small plant installed three months ago in my testing laboratory in Spokane, the Mountain Lion G. M. Co. ordered the installation of a Hendryx agitator in their mill at Republic, to follow their crushing plant of heavy stamps and Huntington mills. This work is now being done and the plant should be in operation by the time this is published. The owners of Republic mines are watching this mill with almost breathless interest.

The agitator now going in is 16 feet in diameter, with straight sides 9 feet high and a conical bottom 8 feet deep. The central well is 2 feet internal diameter. Its capacity is about 100 tons per day, on the supposition that three charges can be worked in twenty-four hours.

Whether or not a success is made by this process on the peculiar ores of Republic (and it is rather hard on the process that its first trial in this section should be on these difficult ores), the process is worthy the attention of any progressive mining man. It consists of agitation of the crushed ore with a very dilute solution of potassium cyanide, and the deposition of the dissolved gold and silver upon plates by means of an electric current at one operation. The pulp of proper consistency is charged into the agitator, together with enough alkali to overcome its acidity and sufficient cyanide to bring the solution to .05%. This agitator is the essential mechanical feature of the process. It consists of a cylindrical tank having a conical bottom of 45° pitch. In the center of the tank, and extending nearly to the bottom and top, is a cylindrical well in which revolves a vertical shaft, supported and driven from above the tank. On the shaft are secured three screw propellers, and in the center of the shaft, which is hollow, is the stem of the discharge plug at the bottom of the tank, operated by a hand wheel at the top of the shaft. A circular apron extends from the top of the well in all directions toward the sides of the tank, having a slight slope outward. Underneath this apron and outside of the well are supported the anode and cathode plates, supplied with current by a small plating dynamo.

The revolution of the shaft carrying the propellers creates a strong upward current in the shaft, and the result is a rapid and uniform circulation of the whole charge upward through the well and downward among the electrically charged plates. When the assays show that the operation is completed the plug is drawn up and the pulp discharged into a settler, whence the separated solution is pumped back to the stock tank and the tailings sluiced out.

The claims made for the process by its inventor are:

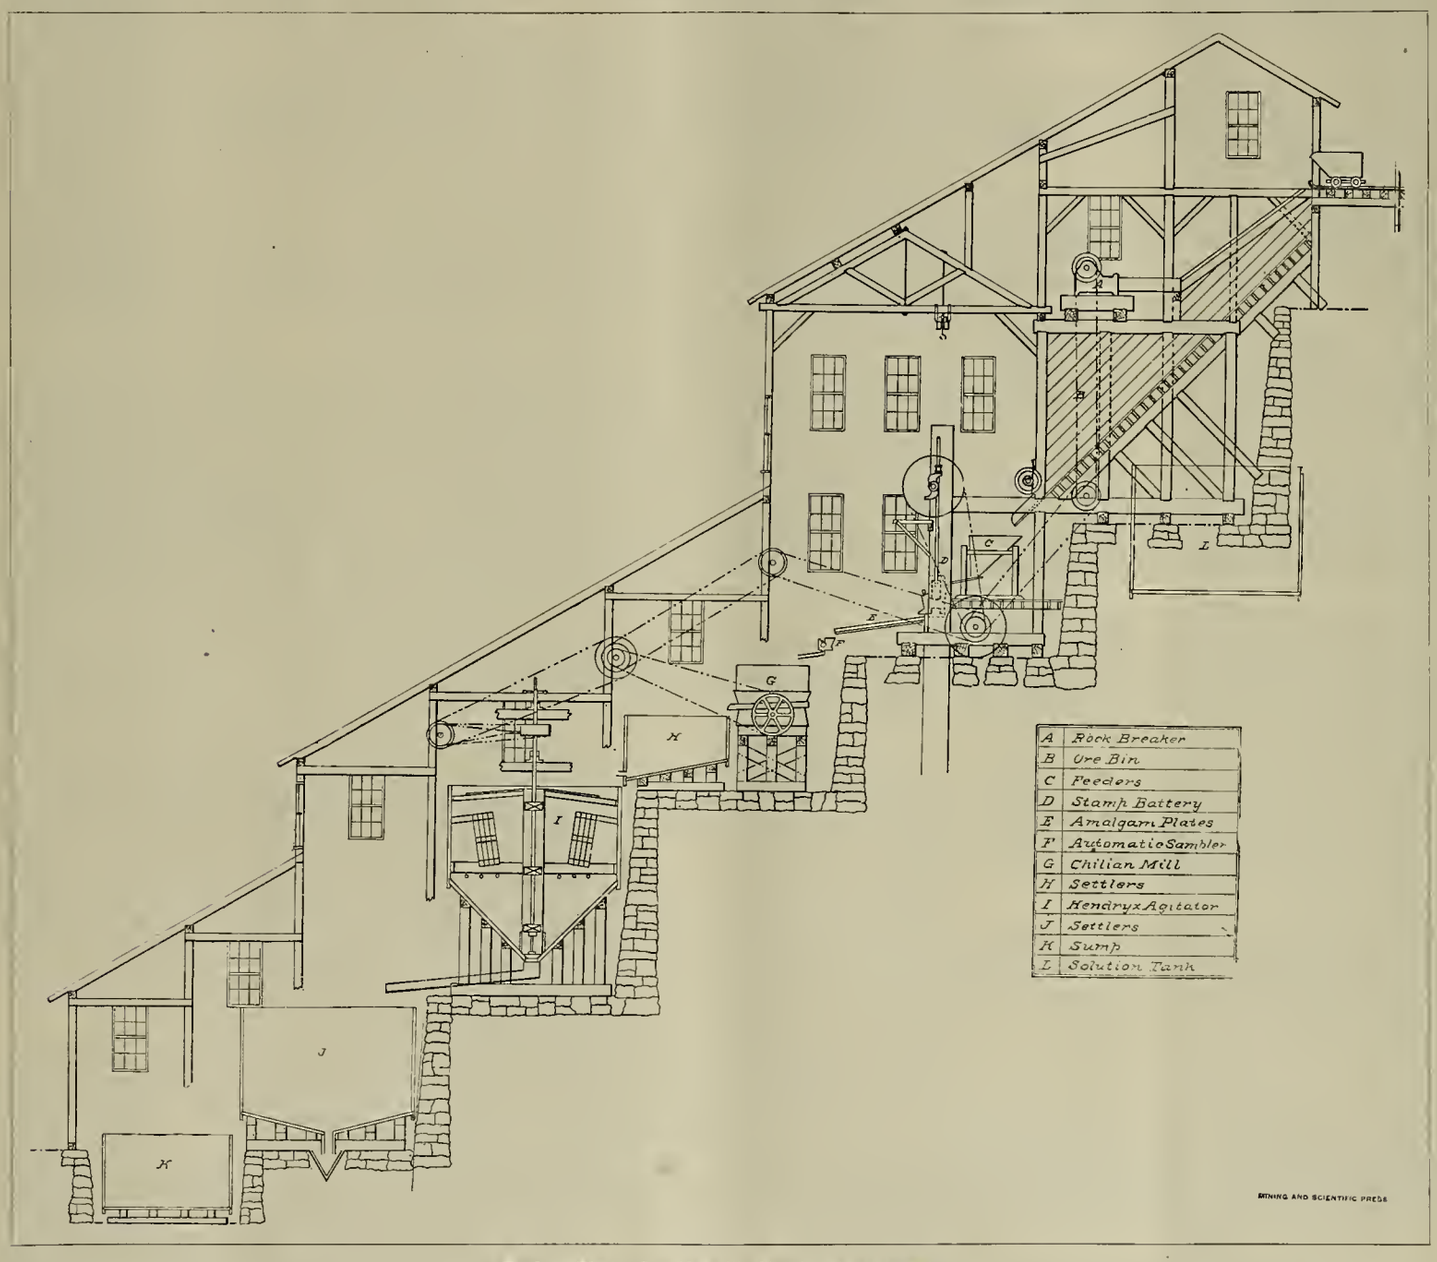
First—That it will extract all the values that any cyanide process can.

Second—That it will deposit the precious metals in the form of marketable bullion without the intervention of any troublesome precipitating and refining process.

Third—That it will make the extraction with less cyanide, on account of the perfect aeration and the regenerating action of the electric current.

Fourth—That it will do this work at a much less expense for plant and operating costs than the ordinary methods.

Fifth—That it is especially adapted to handling tailings and slimes from amalgamation and concentration plants already equipped and running.



Hendryx Electro-Cyanide Mill, Showing Arrangement.

Any metallurgist will recognize the fact that there is little novelty about the Hendryx process, but if he has had experience in trying to agitate fifty tons in a vat, or to pass a constant current through a charge of pulp which is not of regular and stable consistency, he will appreciate the utility of a machine which will agitate 100 tons as readily and as completely as one, which will keep the pulp in perfectly homogeneous condition, aerate it thoroughly, and which cannot be stalled by a momentary shut down of the power.

In the three months I have been experimenting with this process we have treated all classes of ores from many States. When the precious metals in an ore are not soluble in cyanide, the Hendryx agitator will not make them so; when they are soluble or can be liberated by fine grinding, I believe the machine will treat them quicker and cheaper than any other known method.

Three years ago I was employed to make a series of cyanide tests for a company operating in Mon-

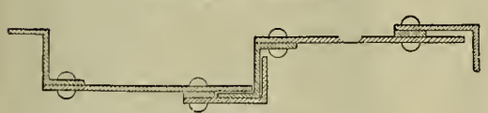
tana. They had a very porous, thoroughly oxidized ore, on which a small cyanide mill was doing very good work. A new mill with a capacity of 200 tons per day was constructed and is now in successful operation on the property. The ore is treated in vats from six to eight days. With the Hendryx agitator we made an extraction of 97.4% of the gold in this ore, at twelve mesh, in four hours, with a cyanide consumption of less than one-fourth pound per ton of ore. One 16-foot agitator would have a daily capacity of over 200 tons, and the metal would be in the form of bullion instead of a troublesome zinc slime.

I know this sounds like the claims of an inventor, but I never invented anything and have no interest in the exploitation of this or any other process. I know the experiments have been carefully conducted under my immediate supervision, and that the results have been as stated. If there is any reason why our experiments will not yield like results on a larger scale I do not comprehend it. The Hendryx process will not work on every ore, but that it is a very valuable addition to the metallurgy of gold and silver I am fully convinced.

Interlocking Metal Piling.

In engineering work some method is often needed for effective and economical ways to overcome difficulty experienced in sinking mine shafts and other forms of excavation, more especially where there is danger of caving or where the material must be immediately protected. In cofferdam work, in cases where quicksand, etc., is encountered, some quick work and satisfactory mode of handling the excavation is of economic value. Some time ago considerable interest was elicited by the publication herein of details of the Poetz freezing process, a method not always immediately applicable. Herewith is illustrated a new and effective device for such immediate

Sheeting Not Interlocked.



Sheeting Interlocked.

use—an interlocking metal sheet piling to be used in constructing retaining walls, deep foundations, cofferdams, submarine work, sinking mine shafts, etc., and all kinds of earth excavation, particularly where quicksand is encountered. The sections of this sheet piling are of standard rolled shapes and are composed of 15x⅜-inch plates, 4x⅜-inch Z-bars and 6x3½x⅜-inch angles and can be obtained up to 60-foot lengths. These sections are readily interlocked and are to be driven successively, thereby rendering the sheeting water-tight, strong in structure and efficient in use. Great strength is obtained in this form of sheet piling, inasmuch as the web of the Z-bar is parallel with the line of pressure. An important point is the saving in weight of metal used in this form. This sheet piling can be pulled and redriven many times, and when through using can be discarded at a high scrap value. This piling is driven with the ordinary pile driver, and the makers say, can be driven through any kind of soil. A model will be sent upon application.

This is made and furnished by the H. Wittekiud Interlocking Metal Piling Co., Cable Bldg., 28 East Jackson Boulevard, Chicago, Ill., who will furnish detailed information on request.

Phosphorescent Sphalerite.

To the Editor:—Commenting upon the article by Dr. Eakle, in your issue of January 23d, upon "Phosphorescent Sphalerite," I beg to call attention to the fact that phosphorescent, or more properly "triboluminescent" sphalerite, has been known for years in the mines of Butte. There is a copper mineral here (enargite) which in luster and cleavage and by candlelight resembles zinc blende; and it is a common practice for miners and shift bosses to determine whether an ore is rich by reason of its content of copper or poor because of the zinc by scratching it with the point of a candlestick or even a piece of wood. The blende shows streaks of light upon rubbing; and the enargite remains dark. Horace V. Winchell.

Butte, Mont., Feb. 19, 1904.

The mining code of the Philippine Islands permits no extra-lateral rights on quartz locations. The locator takes 1000 feet square instead of the usual rectangular location. A discovery of mineral in place must be made, and the location must be recorded. No person, company or corporation can hold more than one claim on one vein, which is an unwise law, as it practically prevents large mining operations, only justified by a large number of claims. This phase of the law has been the subject of much discussion, and its repeal recommended. The provisions of the Federal law as to annual labor, forfeiture to co-owners, etc., is also operative in the Philippines.

Cyaniding in the Southern States.

Written for the Mining and Scientific Press by Ernest Gayford.

The Colossus Gold M. & M. Co. is probably the first to successfully apply the cyanide process for the recovery of gold from the low-grade ore of the Southern States.

Their 100-ton plant has now been in operation on the large deposit of tailings from the old Howie mine, 20 miles north of Charlotte, N. C., since June, 1903, and has proved a marked success.

The writer entered the service of the company in July, 1902, with instructions to thoroughly test and examine the ore from the Howie mine and the tailings from the numerous old mills, as to their adaptability to successful treatment by modern methods of cyaniding as practiced in the Western States.

The Howie is one of the oldest mines in the Southern States and has produced by mint returns over $700,000. It has been operated off and on since 1882, the ore being mined in an extremely primitive manner and treated in arrastras and drag mills, amalgamation being the only known method of saving the gold.

From 1885 to 1890 the mine was operated on a somewhat more extensive scale than formerly; but the methods were still crude, saving poor and appliances out of date. The only assay office was at the U. S. Mint in Charlotte, and this was very rarely patronized; so that the management at that time was working in the dark, simply calculating the value of the ore by what was saved in the mill. Even to-day it is very hard to convince the old-time Southern miner that an accurate value of ore per ton can be obtained from an average sample carefully assayed, and, unless free gold is visible after panning, the ore is immediately condemned as utterly valueless.

The first work to be done was to ascertain the values contained in the old tailings dump, and then, should they be found to warrant further research, to determine whether the material would yield commercial returns if treated by any modern chemical process.

The main tailings bed was from one-half to three-quarters of a mile in length, 50 to 100 feet wide and varying in depth from a few inches to 4 feet, and in one place 6 feet; it was the product from drag mills and arrastras, some of it over seventy years, and none of it less than ten years old.

The tailings were thickly covered with vegetation and undergrowth; in some places large trees had grown upon them and in numerous places crops of green corn were flourishing.

The mills had ground the ore to a fine powder, so that over 90% passed a 100-mesh laboratory screen. The ore as it came from the mine carried a good deal of iron pyrites; this had been decomposed into ferrous sulphate, and, taking it altogether, it looked from a cursory inspection about as unpromising a material to handle as could possibly have been manufactured.

After having the tailings bed cleared of trees, brush and undergrowth, it was laid out into blocks 50x100 feet, each block numbered in rotation, and sample holes dug down to the natural soil, 25 feet apart, from each corner post diagonally across each block. From each hole samples were taken, the value of each block ascertained separately, and a careful record kept of the gold value of each block for future reference.

The values were found to be such that, should the material be amenable to treatment, a good profit should be forthcoming. We were, therefore, ready to proceed with our tests.

The two great stumbling blocks anticipated against cyaniding were abnormal consumption of cyanide, due to decomposed sulphides, roots and other organic matter, and the "unleachability" of the material, due to its fineness.

After numerous small tests on pound samples with varying strength solutions, percentages of lime, and time in contact, it was found that the gold was soluble, indicating, so far as so small a sample could show, that the material would leach without artificial means to assist it, but that the consumption of cyanide was very large—in fact, almost all the cyanide was consumed, the fresh salt having to be added with each solution before returning it on the charge.

A qualitative analysis of the solutions showed that the consumption was due to the organic matter, rather than to sulphates in solution.

We then decided to screen a 500-pound sample through a 6-mesh screen, to free it of nearly all the foreign matter, and, as the tailings carried an average of over 12% moisture, it was evident that we must eliminate this first; so the sample was dried, screened and treated with a standard solution of 0.3%, followed by weaker solutions and waste water, the gold-bearing solutions being run through zinc shavings to ascertain the percentage of precipitation.

The result of this test showed us that drying and screening increased the extraction about 5% and decreased the consumption of KCy down to about two pounds per ton; also, that in a fairly clean solution we need anticipate no trouble in our zinc boxes.

This test was verified by further tests, and we were ready to start on plans for the erection of a tailings plant.

It may be noted here that subsequent mill work showed us that our preliminary work as to sampling, measuring and laboratory tests were accurate.

The plant was designed and erected by our consulting engineer, Frank P. Callow, a Western man, and was briefly as follows:

The tailings, after being cleared off, were shoveled from different places in the dump into dump wagons, each holding 26½ cubic feet, or one ton, and drawn by two mules; these were dumped into an inclined pit leading to a bucket elevator; here eight pounds of dry slacked lime per ton were mixed with it and it was shoveled into the elevator boot, from whence it was raised to a storage bin of 200 tons capacity. From here it was fed by an automatic feeder into a rotary dryer. This delivered the dried material into the second elevator, which lifted it into a 4x8-foot, 4-mesh revolving screen, which screened out all roots, etc., the cleaned tailings dropping into a small receiving bin. The roots, etc. (oversize) were carried off by a chute set at a 60° angle.

From the receiving bin it was taken by cars and dumped into the leaching tanks, six in number, each being 28 feet in diameter and 5 feet in the clear, and holding 100 tons.

We found that material of such fineness, carrying so much water, would not move of its own momentum at any angle, "standing back" even at an angle of 70°. This necessitated a shoveler to help it along wherever it stopped, and in this matter we were very materially helped out by the cheaper labor of the South.

Leaching took five days, the residue being sluiced out by water under pressure obtained from a 5½x3½x5 duplex steam pump.

Somewhat well established theories were upset in our leaching operations. Material of which 91.20% passed a 100-mesh screen leached comparatively freely; the gold was practically all dissolved by the forty tons of 0.3% solution used to saturate the charge; fresh water, used to displace this, gave just as good results as if it were followed by further KCy solutions, and the precipitation was perfect, in spite of the fact that the solution at the head of the strong zinc boxes rarely carried more than 0.05% free KCy, and at the weak end boxes not more than 0.025% KCy.

Although no trace of copper could be found in the tailings by any chemical analysis, the zinc in the lower compartments of the zinc boxes often showed a bright copper color, which, however, interfered in no way with the precipitation of the gold.

It was found necessary to keep the stock solutions thoroughly aerated by supplying free air to them in the stock tanks. This not only kept the consumption of KCy down to its right place, but also assisted in extraction. For this purpose a small air compressor was used and a continuous stream of air was led into the solution in each of the stock tanks.

The tank floor was open, the belting and storage bin having only a temporary roof over them, the plant, including machinery, tanks, lumber, erection and all equipment costing in the neighborhood of $10,000, the boiler and engine being on the mine at the time of its purchase.

We were by these methods able to make an extraction varying from 80% to 90% on what at first seemed a very uninviting material at a cost per ton of $1.03, of which 45 cents was for chemicals.

Comparing costs here with those in the West, we find:

	South.	West.
Labor, per day	60c to $1.50	$3.00 to $4.00
Cyanide, per pound	20½c	30c.
Cordwood	75c	$3.00 to $7.00
Lumber, per M	$5.00 to $6.00	$14.00 to $30.00

This last item is for sawing and delivering of lumber cut on company's land, of which there is an abundance.

It will be seen from these figures that there are extraordinary natural advantages here.

We are now preparing to build one section of a large dry-crushing cyanide plant, to treat ore from the Howie mine. The vein has been open-cut for a distance of 200 feet and a shaft for the lower levels is making good headway.

It is the purpose of the management to keep increasing their milling capacities year by year as developments warrant until a plant of adequate size to handle the ore from such an immense deposit, as the Howie vein is proving itself to be, has been attained.

There are numerous good gold properties in the South that are only needing capital and intelligent handling to assure astonishing results; but for some reason mining here seems unpopular, especially to the average Southerner. While one may be interested in cotton he will receive the sympathy and support of every one; but should he try to produce that even more necessary article—gold—he will be looked at askance by all and with pity by many.

The Colossus Gold M. & M. Co., under whose auspices the above work is being done, is under the management of Gill S. Peyton.

Some Features of Mining Operations in the Homestake Mine, Lead, South Dakota.

NUMBER III.

Written for the MINING AND SCIENTIFIC PRESS by
BRUCE C. YATES, E. M.*

The holes are drilled about 6 feet deep and fully 5 feet of ground is blasted out with one round. Ingersoll-Sergeant rock drills—D24 and D32—are used. Where two machines are used mouuted on one bar, one helper attends to both, and the same number of holes can be drilled in a little more than one-half the time required when only one machine is used.

Figs. 9, 10 and 11 show the manner of placing holes in face of drifts.

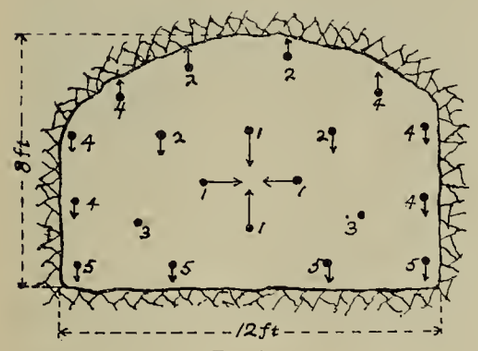


FIG. 9.

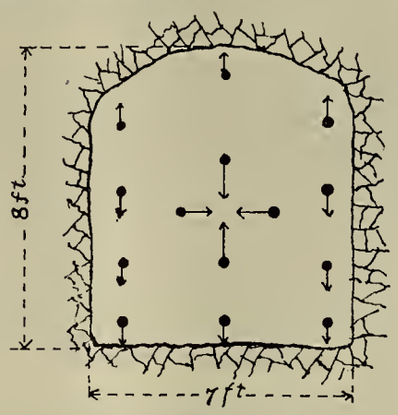

FIG. 10.

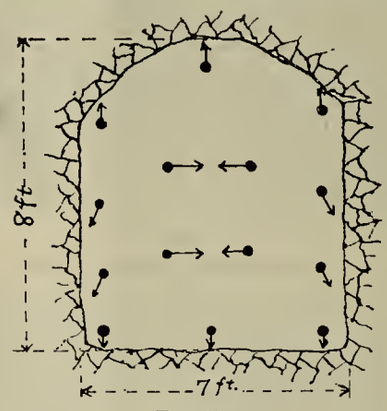

FIG. 11.

Distribution of Holes in Drift, Homestake Mine.

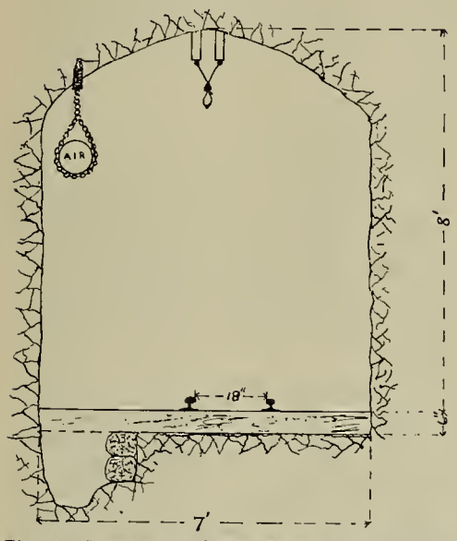

Fig. 12.—Cross Section of Drift, Showing Air Pipe, Drain and Electric Light.

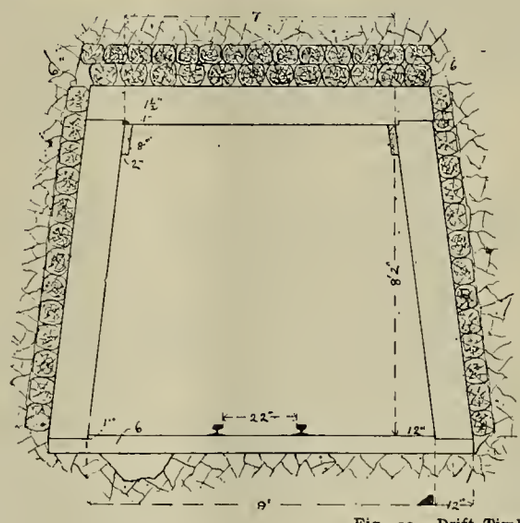

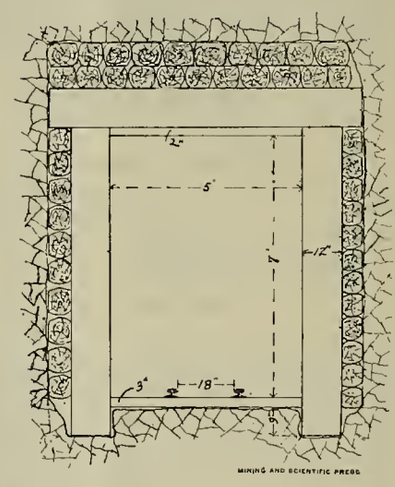

Fig. 13.—Drift Timbering.

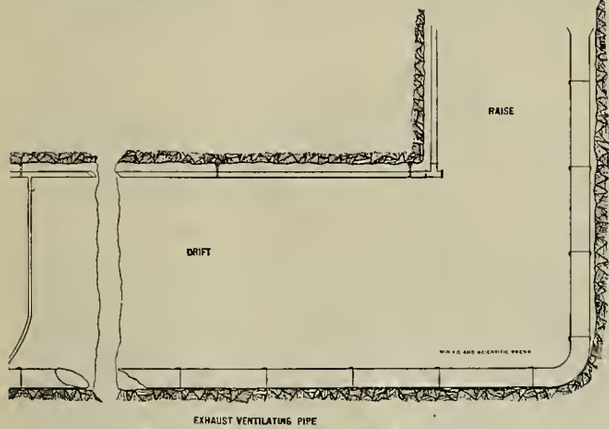

Fig. 15.—Exhaust Ventilating Pipe.

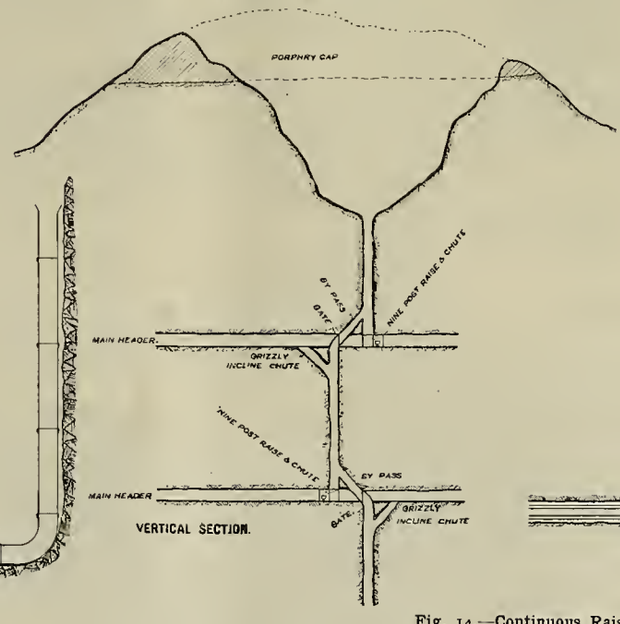

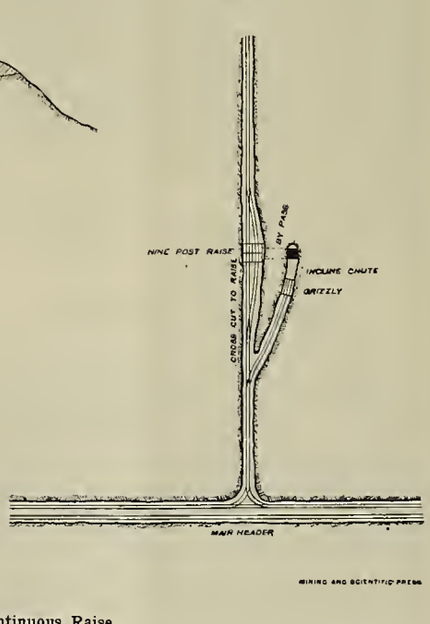

Fig. 14.—Continuous Raise.

The number of cubic feet of rock excavated at each round is (7x8x5 feet) 280 cubic feet. Ten cubic feet of this rock will weigh 1 ton, so that 280 cubic feet = 28 tons. Dividing $41.15 by 28 gives $1.47 as the cost of excavating 1 ton of rock from the face of a 7x8-foot drift. It may be of interest to note in connection with the weight of the rock that the shovelers will have to remove from twenty-five to thirty cars of broken rock. Homestake mine cars have a volume of 20 cubic feet. This would indicate that the volume increases 100%.

Tabulating the cost of double-track 12x8-foot drifts in a similar manner gives the following:

One miner, three shifts, drilling, at $3 50	$10 50
One helper, three shifts, drilling, at $3	9 00
One miner, one shift, blasting, at $3 50	3 50
One helper, one shift, blasting, at $3	3 00
One shoveler, three shifts, at $3	9 00
Explosives—Powder, caps and fuse	16 90
Blacksmith labor, repairs, and machine shop labor	6 50
Total cost of 5 feet	$58 40
Cost per foot	11 68
Cost per ton of rock excavated	1 22

This statement shows a decided reduction in cost per ton in comparison with the smaller drift, and this is as it should be, for it is well known that rock can be broken more easily from a large face than from a small one.

Crosscuts and drifts in ore are from 18 to 24 feet wide and 10 to 12 feet high. These being more or less irregular, no estimate of cost can be had. It is, perhaps, needless to say that per ton of rock excavated the cost is materially less than in smaller drifts.

As there is very little water in the Homestake mine, considering the extent of the openings, the main working drifts are run on a nearly level grade. No working track has a grade greater than 1%, and most of the long headers have a grade of 0.2%. The drainage is provided for by a ditch 1 to 3 feet deep at one side of the drift. Long stringers of 6-inch plank extend across the ditch and are supported by lagging at one end, while the other end rests on the ground. These stringers are spaced about 12 feet apart aud serve as ties. Short ties are used between the stringers.

Fig. 12 represents a cross section of a 7x8-foot drift, and illustrates the method of taking care of the water, laying the track, the position of the air pipe and electric wires.

*Copyrighted.

In some cases the air pipe is laid on the stringers, directly over the ditch. This method is preferable where there are not too many crosscuts, as it does away with a considerable expense in providing hangers for the pipe. When the pipe is suspended the electric wires may be supported by wooden cross arms, which are fastened to the pipe by a yoke made of round or strap iron. When required, tunnel sets are put in, but they present no unusual features to the average mining man.

Fig. 13 shows the usual manner of timbering.

Raises.—Raises are made for one of four purposes, namely: ventilation, ore storage bins, transferring ore or waste from one level to another, or to provide an opening through which waste may be dumped into a finished stope.

Permanent raises for ventilation, ore bins, etc., are located in the country rock far enough away from the ledge to be undisturbed by mining operations.

The purpose of the waste raise is to provide a storage for waste taken from dead work when not immediately needed in the stopes, and are so arranged that waste may be drawn out or dumped in on any level. The main waste raises are connected with the surface, and the porphyry, which here forms a cap overlying the vertical formation, is drawn through them and used for filling.

Fig. 14 gives an idea of the arrangement of one of these continuous raises, which may be used for waste or ore. The ore raises do not, as a rule, connect with the surface.

The method of procedure is as follows: On one or several levels, if convenient, crosscuts are driven to the point from which it is desired to make the raise. Care must be taken to have the crosscuts on the different levels alternate on each side of a vertical plane. When the crosscut has been driven far enough beyond the position of the raise to provide a passing track for empty cars the drift is widened, four sets of regular stope timbers are put in, in the form of a square, and an ordinary board chute located in one set. Above these timbers the raise is gradually drawn in to a 6x6-foot raise. From this point the raise is carried up in the usual manner. Sprags across the raise, about 5 feet apart, are used to sustain the working platform and serve as a ladderway. The smaller size machine drills are used for drilling and are raised and lowered by rope and pulley. The raise on the level below is located about 15 feet to one side or the other, and is raised straight to the upper level. After connection has been made an inclined by-pass is made to connect with the upper raise above the timbers.

Another small inclined raise connects the lower raise with the crosscut at the top of which are located the grizzlies. The bars forming the grizzlies should be spaced about 1 foot in the clear so that no large rock can get into the raise. The successful operation of these continuous raises depends in a great measure upon the grizzlies. The by-pass is closed by a gate made of steel plate, sliding in cast-iron grooves fastened to upright timbers, and operated by rack and pinion. This gate is used in the main ore bins under the crushers and is made at the company's shop. It has the advantage of being easily operated, and can be operated gradually, which prevents rushes of rock. Similar arrangements are made on the other levels. As soon as one raise is made it can be put into service and the raise from the lower levels finished when needed.

In making an ore storage bin, the timber sets are carried up six or seven posts high. When connection is made with the level above the timbers are removed, with the exception of the sill floor in which the chutes are located. The by-pass and small raise to the grizzlies are located as in the waste raise.

Ingersoll A-32 machines are usually used in making raises. One miner and helper will make a 6-foot by 6-foot raise 100 feet high in ordinary ground in sixty shifts, provided they are not required to "car" the rock. Blasts are fired by ordinary caps and fuse. Forty per cent dynamite is used as elsewhere in the mine. The manner of placing the holes is similar to that used in small drifts.

When a stope has been worked nine or ten floors high, raises are put up in convenient places to the level above, through which the filling is dumped. These raises are all in ore and consequently pay their own way.

When a raise is to be made near the face of a long tunnel where the air is bad some artificial means of ventilation must be provided. A device which I believe originated with one of the assistant foremen has proven very successful. A 6-inch or 8-inch light iron pipe is laid from the entrance of the drift to the foot of the raise. Near the entrance a small ½-inch pipe is tapped into the main air pipe and brought down to and into the large pipe with the end which projects into the pipe turned out. It has been found that a very small amount of air which has a pressure of from seventy-five to eighty pounds will effectually clear the raise in a few minutes. This device is used also in running long drifts. An exhaust fan would possibly be a more economical machine so far as power is concerned, but the first cost would be greater, and the air is used only when the machine drill is not in service.

The arrangement of the pipes is shown in Fig. 15.

(TO BE CONTINUED.)

Hydraulic Mining in Cariboo, B. C.

NUMBER II.—CONCLUDED.

Water Supply.—The quantity of water available for use during the season of 1903 was 52,437 miner's inches less than the quantity of water used during the season of 1902, 131,167 miner's inches less than the quantity of water used during the season of 1901, and 333,795 miner's inches less than the quantity of water used during the season of 1900.

Precipitation for season 1902, inches	23 40
Precipitation for season 1903, inches	17.48
Less than precipitation for season 1902, inches	5.92
Quantity of water available and used during season of 1902, miner's inches	179,520
Quantity of water available and used during season of 1903, miner's inches	127,083

The winter snowfall turned out again below the average for the district and fell 26.67 inches short of that reported for 1902. The spring and summer rains turned out also below the usual average and fell 1.41 inches short of the precipitation reported for season of 1902.

The snow went off during the months of April and May under the most unfavorable weather conditions, i. e., moderately warm days, cold nights accompanied by northerly winds, and contributed but a small percentage of its water to the reservoir lakes. The unusual shortage in precipitation, together with the unfavorable weather conditions under which the snow went off, accounts for the shortage in the season's water supply.

SUMMARY OF MINING OPERATIONS FROM THE TIME OF COMPLETION OF WATER SUPPLY SYSTEM IN 1898.

Year	Precipitation in Inches.	Water Used in Miner's Inches.	Time Run. Days.	Time Run. Hours.	Cubic Yards Gravel Washed.	Product.
1899	28.65	353,056	144	8	1,952,535	$ 92,678 93
1900	30 67	460,878	171	13	1,843,938	350,085 77
1901	29.30	258,250	104	13	2,430,288	142,273 41
1902	23.40	179,520	65	15	630,442	61,395 19
1903	17.48	127,083	53	7	373,000	44,943 70

In 1899, the season's operations were confined, mainly, to cleaning out the deposit of boulders and debris left in the bottom of old Chinese workings, and the low-grade deposits of gravel and volcanic mud lying on the rims north and west of said old workings, which accounts for the light product in proportion to the quantity of water used.

The precipitation for season of 1900 was 30.67 inches, and made, with the 100,000 inches carried over from 1900, 480,878 miner's inches of water available for use, a quantity exceeding the estimated holding capacity of the reservoirs, aggregating 470,370 miner's inches, as shown by the following table that accompanied the hydrographic map prepared in 1897.

TABLE OF WATER SUPPLY.

Locality.	Watersheds. Area. Million Sq. are Feet.	Area. Acres.	Area. Sq. Mile.	Reservoirs. Depth, Feet.	Top Area. Square Feet.	Top Area. Acres.	Bottom Area. Square Feet.	Contents. Million Cubic Feet.	Contents. 24 Hrs. Min. Inches.
Polley's lake	337	7,736	12.09	8	40,660,000	933	35,400,000	304	140,741
Bootjack lake	174	3,965	6.24	6	27,500,000	631	26,500,000	162	75,000
Main ditch, below Hazeltine	352	8,081	12.63						
Main ditch, above Hazeltine	155	3,558	5.56	33	27,000,000	620	8,000,000	550	254,629
Dancing Bill	79	1,814	2.83						
Morehead lake	460	10,560	16.50						
Little lake, above Morehead ditch	99	2,273	3.55						
Totals	1,656	38,017	59.40			2,184		1,016	470,370
Little lake, below Morehead ditch	95	2,180	3.41						

By reference to section No. 4 on the longitudinal section accompanying this report, it will be noted that the intrusion of an immense deposit of slide rock replaced a large area of high-grade gravel and reduced the average yield of the ground. This condition, together with the light precipitation and short water supply, accounts for the reduced product for that season.

The short water supply and inclusion of large deposits of slide rock in the lower bench accounts for the light product for the seasons of 1902 and 1903.

The tables indicate that the product is dependent mainly upon copious precipitation and a water supply ample to operate the mine full time with at least 2500 miner's inches of water during the open season, including a period of about six months, commencing on or about May 1st and ending on or about November 1st.

It is, therefore, evident that the precipitation must return to what it was prior to 1894, as reported by government agents and old settlers, varying each season, with few exceptions, from 30 to 40 inches annually, or the company's catchment canals must be extended to control a much larger area of watershed, or to some stream affording an abundant and permanent flow of water throughout the season. Surveys are now under way to determine the possibility and probable cost of extending the system to a source that will insure an abundant and permanent water supply that will be ample to carry operations over seasons of light precipitation.

The heavy precipitation recorded for September ultimo, amounted to 6.24 inches and caused the water in the storage reservoirs to rise as follows:

Morehead lake, rise 86 inches, being now 13 inches lower than maximum height. Polley's lake, rise 20 inches, being now 3 inches higher than for 1903. Bootjack lake, rise 15 inches, being now 5 inches higher than for 1903.

With so large a quantity of water on hand in the reservoirs the outlook is certainly favorable for a good water supply for the ensuing season.

The outlook for the ensuing season's operations is, therefore, very favorable for a large output at reduced cost, calculating, of course, on the precipitation being ample to afford a good season's water supply.

The receipts and expenditures attending the operation of the company's mines for the season will be found in the following statements:

MINE OPERATING EXPENSES, 1903.

EXPENDITURE.

Mining account—		
Mining	$18,330 22	
Excavation for sluices	8,703 00	
		$27,033 22
Explosives—		
Mining	$ 7,418 15	
Excavations for sluices	1,120 00	
		$14,538 15
Sluice maintenance and extension		9,449 80
Portable hydraulic plant maintenance		37 33
South Fork ditch maintenance		2,870 38
Morehead ditch maintenance		2,815 84
Camp maintenance		1,189 50
Mine and camp light maintenance		398 46
Wagons and harness maintenance		144 07
Telephone maintenance		77 57
Prospecting account		729 22
Stationery and printing		283 47
Postage and telegraph		134 34
Incidental expenses		11 40
Lands and leases (lease purchases, rentals, etc.)		5,267 30
License account (free miner's certificates)		110 00
Fire insurance		803 00
Traveling expenses (transportation of miners, etc.)		6,030 87
Mine office expenses		1,307 00
Bullion expenses (royalty, insurance, transportation, etc)		1,633 24
Management		5,228 18
Stable expenses		628 85
Tools and implements, loss for season		288 70
Horses account, loss for season		190 00
Quicksilver account, loss for season		242 69
Total operating expenses for season		$81,451 57

RECEIPTS FOR SEASON 1903.

Gold product for season	$44,943 70
Profit on stores sold	2,123 19
Total receipts for season	$47,066 89

INVENTORY.

There is on hand at the company's stores and mines, as per inventory made August 5, 1903:

Miscellaneous provision stores, mining supplies, hydraulic plant, etc	$42,783 81	
Explosives	20,764 50	
Blacksmith stores	1,724 63	
Quicksilver	2,644 60	
		$67,917 63
Horses	$ 1,192 00	
Wagons, sleighs and harness	2,109 92	
Saw logs, lumber, flats, fuel, sluice blocks, etc	7,943 74	
Tools and implements	15,557 40	
		$26,803 06
Total as per inventories		$94,720 69

Mineral Resources of Uganda.

Uganda is one of the countries of east equatorial Africa, and this section, like many other portions of Africa, has been prospected in a superficial and hasty manner, in the hope of finding gold-bearing deposits. The English consul general at Entebebe in his annual report, recently issued, says that so far prospecting for precious minerals in Uganda has led to no practical results. It is known that there is gold in certain parts of the protectorate, but the question, of course, is whether it can be worked at a profit. The East African Syndicate sent prospecting parties through the protectorate during the year and took up an extensive prospecting area of 100 square miles along the bluff to the end of Lake Albert, but after a time these parties were withdrawn to join the exploration parties in the British East African Protectorate. It is to be hoped that they will resume work in Uganda later on. Iron abounds everywhere, and it is reported that there are some indications of coal in Ankole and Busoga, but no specimens have yet been brought to Entebebe. Mica has been found of a quality and size which would pay for working. Salt is produced from the salt pans at Kibero, on Lake Albert, and the salt lake at Katwe, on Lake Albert Edward, and furnishes revenue to the Government. The revenue from the Katwe salt has nearly trebled during the year, owing doubtless to improved methods of manufac-

ture. It is used locally, and would probably not pay for export. A species of Epsom salt has been discovered in Busoga, and has been sent to England for analysis. Alum has been found in Busoga, samples of which were valued in the London market at £3 5s per ton.

The Geology and Copper Deposits of Bisbee, Arizona.*

NUMBER IV—CONCLUDED.

Written by F. L. RANSOME.

In general, the zone in which the metamorphic silicates are developed is that in which most of the ore bodies are found. In the western part of the Copper Queen mine, however, extensive ore bodies occur in limestone that is perhaps outside of this zone. In other words, the deposition of metallic sulphides appears to have had a wider range, and to have extended farther from the porphyry into the fissured limestone than did the formation of the metamorphic silicates.

That the original ore deposition was genetically connected with the intrusion of the granite-porphyry of Sacramento hill is reasonably certain. The other factors, which by their fortunate conjunction determined the original mineralization of this part of the district, were the contact of this considerable mass of porphyry with limestones, the occurrence of the Dividend fault and other less important fractures, and the attitude of the limestone beds with reference to the porphyry and to these faults. The hypothesis is advanced that the deposition of the cupriferous pyrite and the metamorphism of the limestone, schist and porphyry was effected by the mingling of solutions from different sources in the vicinity of the Dividend fault and of the Sacramento hill porphyry. The principal function of the porphyry is believed to have consisted in the supply of heat to such solutions as rose from great depth through the fault fissures and in determining the locus of chemical activity that resulted in the deposition of the ore.

The source of the ore materials is uot known. They may have risen through the Dividend fault from depths far below the bottom of the syncline of Paleozoic rocks. They may have been collected by solutions moving through one or more of the Paleozoic limestones on their way down to the locus of deposition. Lastly, they may have been derived from both sources.

Few, if any, of the ore bodies now known and worked in the Bisbee district were formed directly by the original mineralization just discussed. That process resulted, so far as underground workings show, mainly in the formation of bodies of cupriferous pyrites passing peripherally into metamorphosed and pyritized limestone. These bodies contained originally too little copper to be classed as ore, as that term is defined by present economic conditions of working. Further concentration was necessary, and the profitable ores of to-day have been derived from these pyritic masses by secondary processes involving general oxidatiou, with all of its attendant chemical phenomena, transfer of material, and the local enrichment of certain portions of the sulphide masses by the formation of chalcocite, and, in some cases, of chalcopyrite.

Tbe lower limit of oxidation of the Bisbee ores is very irregular and is apparently uncontrolled by any constant ground-water level. In the Calumet & Arizona mine oxidized ores occur at a depth of 1000 feet, while residual masses of sulphide ore occurs in the adjoining Copper Queen mines within 150 feet of the surface. Masses of lean pyrite are sometimes completely enclosed in an envelope of high-grade chalcocite and oxidized ores.

IV. FUTURE OF THE DISTRICT.—Although more or less mineralization occurs at many points in the Mule mountains, there is little to indicate that any deposits of copper ore will ever be found in the Bisbee quadrangle approaching in importance those already known and probably awaiting discovery in the faulted limestone syncline about Sacramento hill. For more than twenty years the Copper Queen mine has produced an average exceeding 16,000,000 pounds of copper annually. Recently, the Calumet & Arizona Co. has begun energetic operations in ground almost surrounded by the property of the Copper Queen Con. M. Co. Not only is there sufficient ore known in these mines to keep them in operation for many years to come, but there is no clear evidence that the bottom of the ore-bearing ground has been reached in any of these extensive workings. Moreover, the statement may be ventured that the specter of the "lower lime" has hitberto had an undue influence in restricting prospecting to nearly horizontal planes. There is certainly a reasonable hope of finding ore bodies in the Martin and Abrigo limestones beneath the masses that have been so profitably worked in the overlying Carboniferous beds. The occurrence of small bunches of ore iu the Abrigo limestone at the Whitetail and Wade Hampton claims sbows that ore deposition may take place in these lower beds. It may be, tbat owing to their greater depth, such ore bodies if discovered will be found to consist of low-grade cupriferous pyrite, unenriched by the generally descending solutions that have contributed so largely to the value of the known masses. This, however, is a point that prospecting alone can determine. It would seem that near the Dividend fault the conditions are favorable for the continuance of enricbing processes to depths greater than those now reached in this part of the underground workings.

But more than this, it may be pointed out that less than half of the semicircular mineralized zone about the porphyry mass of Sacramento hill has been explored at all. Ore was first discovered at the surface on Queen hill at the northwest end of the zoue. From this discovery, developments have been pushed by underground exploration to the south, often with little or no surface indication of ore. There still remains, however, an extensive area of unknown, but promising ground, lying just south of Sacramento hill and extending eastward toward the southeastern continuation of the Dividend fault, which is here concealed by the Glance conglomerate. This is the eastern half of the semicircular mineralized girdle about the intrusive mass of porphyry. While structurally the beds south of Sacramento hill form a less favorable nook for the deposition and concentration of ores than that enclosed between the Czar and Dividend faults and the northern contact of the porphyry, yet their attitude with reference to the intrusive stock and to the probable continuation of the Divident fault down Mule gulch is distinctly favorable to mineralization. The developments in the Spray and the Calumet & Arizona mines have shown that profitable ore bodies are by no means confined to the structural pocket in the vicinity of the Czar and Holbrook shafts. There is no known reason why they should not yet be found skirting the southern contact of the porphyry for some distance eastward towards Mule gulch. It is thus probable that the ore zone, if present, also turns south along the contact of the limestones with the porphyry, and does not extend eastward under Mule gulch itself.

It is true that the easterly dip of the beds south of the porphyry stock, carries the Escabrosa limestone to a much greater depth near Mule gulch than it has in any of the present workings. It is probable that this depth, a short distance east of the Gardner shaft, may be so great as to preclude the occurrence within the Escabrosa limestone of any but original, unenriched pyritic ore, which may or may not be workable. But judging from surface indications, there has been considerable mineralization of the Naco limestone south of Sacramento hill, and there is nothing improbable in the occurrence of higb-grade ores in this limestone at statigraphically higher horizons than those in which ore bodies have hitherto been found. The exploration of this ground calls for no greater outlay or boldness than is already displayed in other parts of the district with less assured hope of reward.

The outlook for finding profitable ore bodies within the main porphyry stock of Sacramento hill is not regarded as particularly promising. As the dump of the Copper King shaft shows, this rock may be very heavily impregnated with pyrite. But the mineralization seems to tend more to abundant dissemination than to the formation of solid sulphide masses. Even if the latter occur, it is doubtful whether they would be found sufficiently cupriferous to constitute ore. Moreover, the chemical and physical character of the porphyry render it very much less favorable than the limestones to the deep oxidation and secondary concentration that has played so important a part in the genesis of the known ore bodies. Very little exploration of the porphyry has been made, however, and work in this direction cannot be condemned as altogether vain.

In conclusion, it may be said that Bisbee is less likely to suffer from a lack of ore than from a too rapid exhaustion of those bigh-grade oxidized ores which are necessary for the economical smelting, by present processes, of the low-grade sulphides.

* Abstract Trans. Amer. Inst. Min. Eng.

Iron Ore Production in the United States.

The iron ore produced in the United States is divided into classes as follows:

1. Red hematite, including all anhydrous hematites (sesquioxides of iron) known by various names, such as red hematite, specular, micaceous, fossil, slate iron ore, martite, blue hematite, etc.

2. Brown hematite, including the varieties of hydrated sesquioxide of iron recognized as limouite, gothite, turgite, bog ores, pipe ores, etc.

3. Magnetite, those ores in which the iron occurs as magnetic oxide, and including some martite which is mined with the magnetite.

4. Carbonate, those ores which contain a considerable amount of carbonic acid, such as spathic ore, blackband, siderite, clay ironstone, etc.

The amount of red hematite ore mined in the year 1902 in the United States amounted to 30,532,149 long tons, or 85.9% of the total.

During the year ending December 31, 1902, 126 iron ore operations in the United States each produced 50,000 or more long tons of iron ore, the total for the 126 mines being 31,561,628 long tons, or 88.8% of the production for the country.

Of these larger mining operations reported, 102 produced 28,584,023 long tons of red hematite; fourteen contributed 1,303,484 long tons of brown hematite; seven supplied 1,255,358 long tons of magnetite; two mines furnished a mixture of 330,439 long tons of red hematite and magnetite, and one mine a mixture of 88,324 long tons of red and brown hematite.

Of these larger mining operations forty-six are in Michigan, thirty-five in Minnesota, fifteen in Alabama, seven in Tennessee, five in Wisconsin, four each in New Jersey and Virginia, three in New York, two each in Colorado and Georgia, and one each in Pennsylvania, Wyoming and New Mexico.

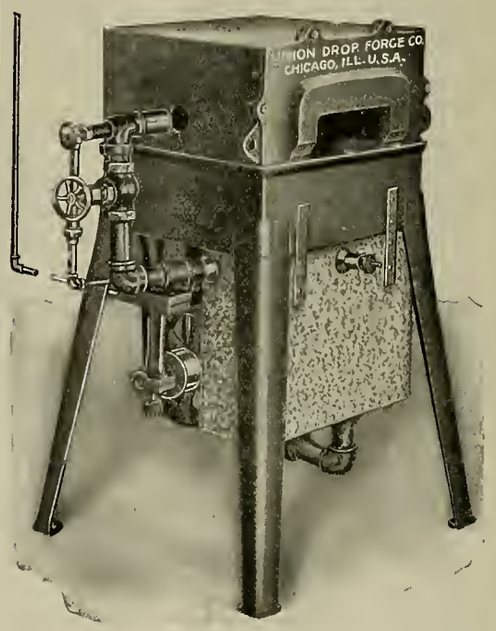
Of these 126 operations, one contributed over 1,800,000 long tons, one over 1,600,000 tons, one over 1,400,000 tons, two over 1,200,000 tons, one over 1,000,000 tons, two over 900,000, one over 700,000 tons, three over 600,000 tons, five over 500,000 tons, three over 400,000 tons, seven over 300,000 tons, fifteen over 200,000 tons, thirty-two over 100,000 tons, and fifty-two between 50,000 and 100,000 long tons.

Fuel Oil Equipment.

The increasing use of oil for fuel gives importance to devices deemed efficient or economical for such use. The use of oil for fuel in smelters has been discussed herein and practical details given.

There are, however, other and smaller systems devised for general use that are deserving of notice. One of these which is worthy of note is the fuel oil equipment illustrated herewith.

The accompanying cut represents a fuel oil equipment designed to combine a heating, tempering and annealing furnace in a small space. To connect the furnace pulley by belt to pulleys on main or countersbaft, attach oil pipe to a barrel or tank of fuel oil, which will put the furnace in readiness for use. To get the best results from this furnace the manufacturers say the fuel oil tank or barrel should be not less than 6 inches to 8 inches higher than the burner, and back from the furnace from 10 feet to 15 feet, or farther still if convenient. When lighting the furnace a free passage of air through the burners should be obtained, after which the oil valve should be opened slowly, the oil naturally mixing with the air, and being plainly discernible. A piece of lighted waste, saturated in fuel oil and placed in front of the spray will ignite. When the flame is started the oil valve can be regulated until perfect combustion is obtained.



Fuel Oil Equipment.

The dimensions of the furnace, No. 11, are: Inside, 12 inches long, 10 inches deep, 9 inches high; the dimensions of the furnace, No. 11, are, outside, 18 inches long, 17 inches deep, 16½ inches high. This furnace is intended to do away with the necessity of an expensive oil equipment such as reservoirs, blowers or compressors, pumps, etc. The furnace can be operated with gravity pressure.

The distinctive feature of this system of burning oil for forging, annealing, hardening, or for any purpose for which iron, steel, copper, aluminum or bronze is to be heated, consists in vaporizing the oil with a blast, the arrangement for doing which is complete in the burner. The blast is either furnished from a fan, blower or steam pipe. When the burner is used in connection with steam the steam is furnished direct from the boilers. When the burner is used with air the blast is furnished through air pipes direct from the blower or fan which is driven direct from tbe shaft by belt. By this system all units of heat in tbe

oil are formed into gas and not stored, so that there is no lost heat.

In addition to the saving in fuel is an increase in the amount of work that can be done in the same time and with a smaller force of men over coal or coke, a forging or welding heat can be obtained within fifteen minutes. This process does away with a storage space for coal or coke, the hauling of same, the smoke, dirt, gas, hauling away of ashes and the consequent uneven heat occasioned by loading a furnace with fresh fuel, a steady and even heat being maintained without a break.

This compact fuel oil equipment is made and furnished by the Union Drop Forge Co., 64-76 E. Ohio street, Chicago, Ill., who will furnish full details on request.

Precautions in Overwinding.

To the Editor:—After reading on page 91 of your issue of February 6th, concerning the accident at the Independence mine at Victor, Colo., I call to mind an occurrence something similar at the Union shaft at Virginia City, Nev., where the engineer ran the cage up to the sheave with eighteen men, none of whom were hurt except those who jumped. The reason that the cage did not fall was that the guides commenced to narrow in about 20 feet above the collar of the shaft, and by the time that the cage got near the sheave the guides pressed so hard on the shoes of the cage that they held it in suspension without the aid of the safeties, and the cage had to be gotten out with jackscrews. I have known of several devices to prevent overwinding, but the narrowing of the guides is the best that I have seen. It is very simple and has a sure grip if the rope parts. I have erected and helped erect a great many frames and I have always put the guides in as here described.

Liscum, Ariz., Feb 20. J. F. Smith.

Manager R. J. O'Neill of the California Gulch shaft at Leadville, Col., thus describes the safety catches placed by him in the head frame of his shaft:

Take a piece of spring steel 4 inches wide by ⅜-inch thick and about 2 feet long. In one end of this drill six holes for ½-inch bolts in a space of 6 inches, which leaves 18 inches for a spring. Heat and bend the spring, giving an offset of 3 inches from a straight line. On the upper end weld a 1¼-inch bolt at right angles to the spring. Have this bolt long enough to go through the guide and have the thread on this extend far enough so that it can be secured through the guide until the spring is out of the way of the cage. In placing the spring on the guide it should be countersunk so that the bolts at the bottom will not interfere with the cage, and so that when the cage passes up through the spring it will not force the guides apart. Place the springs on the guides opposite each other, leaving about a foot between the top of the springs and the bottom of the cage when the latter is at the sheave. Bore the holes for the top bolts so that they will spring back through the guides when the cage has passed, and leave the springs projecting under the cage. To lower the cage it is only necessary to screw the nuts on the upper bolts until the springs are flush with the guides.

With this device on the guides, Mr. O'Neill says the cage can pass to the top of the gallows-frame, forcing the springs out of the way. When it passes the springs they fly back into place, projecting 3 inches from the guides under the bottom of the cage, thus making it impossible for the cage to drop back into the shaft. It would be well, he thinks, to brace the guides at the point where the springs are put on, to prevent them spreading. Mr. O'Neill has placed these springs on several mines where he has been employed and has always found them to work successfully.

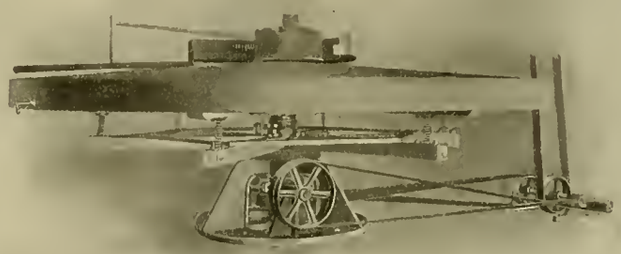
Utility of the Air-Lift Pump.

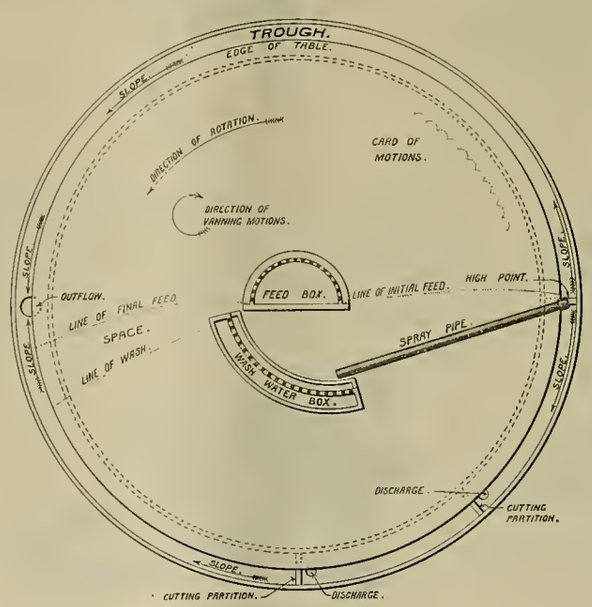
The principle upon which the so-called air lift pump operates is well understood and it has been applied with satisfactory results in mines, on farms and elsewhere, to lift water from streams, wells, shafts and reservoirs in many places throughout the West and in Mexico. The lifting of the column of water in the pipe is accomplished by the introduction of compressed air into the column pipe at a point near its foot. Two of the engravings on the front page illustrate the air lift in operation in Mexico, where it is employed in raising water from a well for irrigation. The total depth of the well is 413 feet, cased to 157 feet, with 7½-inch diameter pipe. The remainder of the well, to a point near the bottom, is cased with 6-inch inside diameter pipe. The depth of water when the lift is not in operation is 125 feet; depth of water when pumping, 128 feet; lift above the surface, 6 feet, making the total lift 134 feet. The diameter of the discharge pipe is 3 inches, and diameter of air pipe 1¼ inch. The horizontal distance from well to tank is 10 feet. The depth of air and water pipe beneath the surface is 308 feet, being about 63% of the radius of submergence. When in full operation 105 gallons of water is lifted per minute. The air pressure when starting is 82½ pounds per square inch, the plant being at an altitude of 7000 feet above sea level. The working air pressure is 79 pounds, and the steam pressure at the boiler is 80 pounds. The compressor used is the Ingersoll-Sergeant class F, with steam and air cylinders, 10x10 inches, running at 150 revolutions per minute. The volumetric capacity of this machine at sea level is 134 cubic feet of free air per minute, which is equal to 105 cubic feet of air at an altitude of 7000 feet. The plant has high efficiency, and the fact that it lifts this large amount of water, about 8½ miners' inches, indicates its usefulness about mines. The same compressor can be utilized for other purposes, running rock drills, etc., in the mine, as well as lifting of the column of water.

The Sperry Slimer.

Among the latest devices designed for the treatment of ore by concentration, and especially for the saving of slimes, is the Sperry slimer, illustrated herewith.

The addition will be noted of a circular vanning motion to the common form of buddle, designed to develop increase of capacity and introducing radically new features and conditions to materially change the methods and general practice of this form of concentration, retaining all the good qualities of the buddle.





The Sperry Slimer.

By the addition of this vanning motion it is expected to make the stratification of the pulp complete before the wash water is added and to allow feeding one-half of the table, thereby giving greater load.

The entire mechanism is supported on a self-contained cast base at the center and beneath the top to protect the working parts from wear occasioned by grit.

Referring to the cut showing the plan of the top, the action will be readily seen. After the surface has been thoroughly cleaned by the spray pipe, it approaches the initial line of feed. From this line the pulp is gradually added to the surface for about one-half of the rotation to the final line of feed, at which point it has received the full load. During this gradual addition, the vauning motion is operating on the pulp to stratify it. The increasing width of the current from the center to the edge is intended to afford an opportunity for the finest of the metallics to settle to the surface, which is soft, smooth rubber.

The wash water is then added in a gentle flow over the silica sufficient to remove it and not break up the stratum of metallics.

The adjustments permit the slope of the top to be changed while the machine is in operation. The size of the circle of the vanning motion can be similarly increased or decreased.

The speeds of both the rotation and the vauning motion are adjustable. These, with the complete control of the wash water, make it possible to obtain the widest range of adjustments, giving a most complete shading to meet all sorts of conditions.

The power required to operate is stated to be about ½ H. P.

The regular size of the table is 10 feet diameter and requires 11 feet square floor space

The point of adaptability to a variable load is brought out by the inventor as an advantage, and he gives as a further reason that the machine does not require a "bed." He states that a capacity of from ten to fifteen tons have been developed under ordinary circumstances. The Sperry slimer is being placed on the market by the Heudrie & Bolthoff Manufacturing & Supply Co., Denver, Colo.

Geology of the Transvaal.

Since the Boer war important additions have been made to the knowledge of the geological structure of the Witwatersrand gold fields, says the London Mining Journal. Much time has been spent in the examination of old workings, and many bodies of ore, previously over-looked, have been discovered, chiefly on the South Reef of the Central Rand. Moreover, the publication of geological maps by Dr. Molengraaf in 1902 and by M. H. de Hora, by T. Kassner and by F. H. Hatch in 1903 indicates that much attention has been devoted to the investigation of the geology of the whole district. In Cape Colony admirable survey work was carried out during 1902 and 1903 by the Geological Commission. Thus, by degrees the gaps in our knowledge are being filled up. The problem is one of great complexity. No fossils are found, and it is necessary to trust entirely to stratigraphical relations or to petrographical similarities over great distances. The geological formations now recognized in the Transvaal may be summarized as follows, in descending order: Karroo system—Coal measures; Dwyka conglomerate. Transvaal system—Waterberg sandstone; red granite; Gatsraud and Magalieburg series; dolomite; Black Reef series; Klipriversberg amygdaloid. Archæan system — Upper Witwatersrand beds; Lower Witwatersrand beds or Hospital Hill series; granites and schists. Three unconformities are shown:

1. Between the Dwyka conglomerate and the Watersberg sandstone.
2. Between the Black Reef series and the Klipriversberg amygdaloid.
3. Between the latter and the Upper Witwatersrand beds.

Of the Witwatersrand beds the upper series consists of quartzites, grits and numerous conglomerate beds with a few slate beds, while the lower series comprises quartzites and numerous slate beds, with few conglomerate beds. The division between the two is taken at the horizon of the conglomerate beds known as the Main Reef series; but the two divisions have been proved by Dr. Hatch to be conformable. There are many interesting problems in connection with the gold deposits still unsolved. G. A. Denny, for example, contends that the slates that characterize the Lower Witwatersrand beds are true igneous rocks.

Dr. Hatch, however, asserts that microscopic examination shows them to be true detrital sediments of quartzite nature, and his extensive experience of microscopic work adds great weight to his opinion. Another question, regarding which there is no general agreement, is the genesis of the gold deposits.

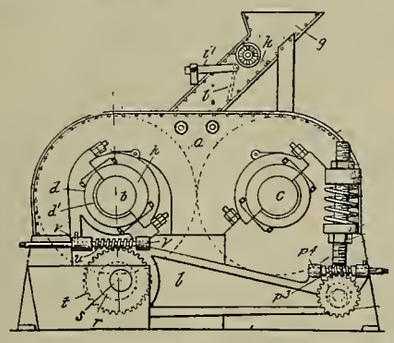
In the explanatory note to his map, Dr. Hatch states the pebbles of the conglomerate consist of quartz, which is apparently derived from the breaking down of ancient vein quartz. In his paper read before the South African Association of Engineers on August 26 last he states, however, that it has always been his view that the auriferous contents of the banket beds were introduced by the agency of underground waters subsequently to the deposition of the conglomerate beds. The advocates of the sedimentary theory and of the infiltration theory both adduce well-considered arguments, and it is difficult to say which has made out the better case. The comparison of the Rand conglomerates with the gold placer deposits of to-day is certainly open to objection, for no such placers have been described with all the gold in bright unoxidized grains of pyrites, as it is in the banket. The bright and unoxidized appearance of the pyrites is not satisfactorily accounted for in any of the theories propounded.

Mining and Metallurgical Patents.

PATENTS ISSUED FEBRUARY 16, 1904.

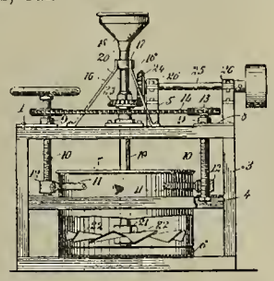
Specially Reported and Illustrated for the MINING AND SCIENTIFIC PRESS.

CRUSHING MACHINE.—No. 751,672; J. H. McCormick, Beartown, Mont.



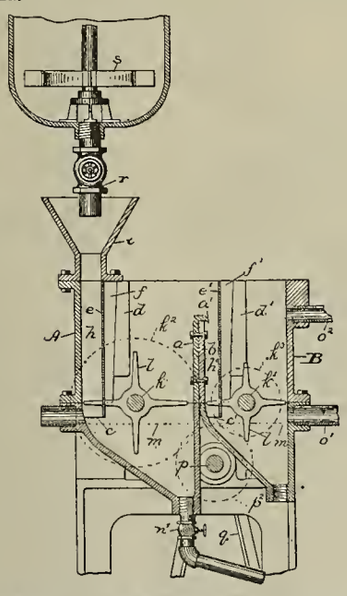
In crushing machine, combination with crushing rolls, of pair of bell crank levers on opposite sides of machine in similar positions, tiltable bearings on corresponding arms of bell crank levers adapted to carry one of rolls, shaft for each of bell cranks journaled in framework of machine, eccentric on arch of shafts rotatably mounted thereon, bell cranks engaging eccentrics at their elbows, meaus for revolving eccentrics independently of each other whereby either end of roll may be given combined vertical and horizontal adjustment, eccentrics engaged by other arms of bell cranks at ends, and means for rotating eccentrics independently of each other whereby arms of bell cranks engaged thereby may be given vertical adjustment independently of each other whereby either end of roll may be giveu horizontal adjustment with respect to stationary roll.

ORE SEPARATOR.—No. 752,027; H. J. Burroughs, Los Angeles, Cal.



A separator comprising main frame, two-part separating tank therefor, means for adjusting one portion of separating tank vertically relative to other, feeder for tank, and means for revolving feeder.

AMALGAMATOR.—No. 752,246; P. J. Nelson, Baltimore, Md.

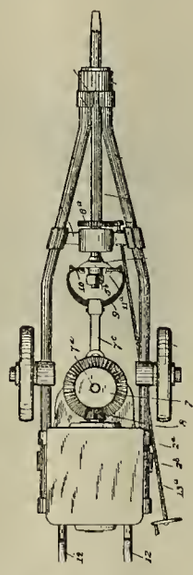


Amalgamator, comprising tank provided with mercury chamber; partition secured in tank and forming therein feed passage for slime and like to mercury chamber, partition being provided in its lower edge with recesses; and revolnble beaters arranged to sweep through recesses into both feed passage and mercury chamber.

GATE AND CHUTE FOR COAL OR ORE POCKETS.—No. 752,555; G. L. Holmes, Chicago, Ill.

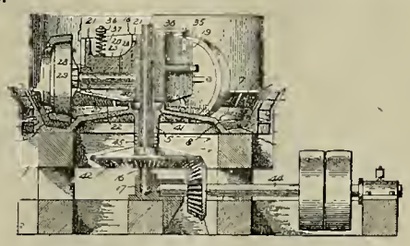
In gate and chute for coal or ore pockets, combination of gate to cut off flow of coal with transverse rod below bottom of discharge way, gate pivoted on such rod, aud outer spout pivoted concentric with but on pivots independent of rod.

MINING MACHINE.—No. 752,180; E. P. Rauscher, Columbus, O.



In mining machine of pick type, combination of frame, socket bearing supported in frame, ball universally movable in socket beariug, pick stock passing through and reciprocable in ball, and means for mechanically rotating pick stock.

ORE MILL.—No. 752,138; W. E. Wild, Denver, Colo.

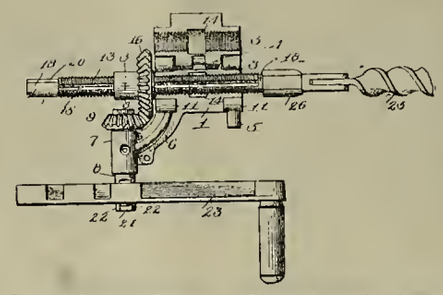


In ore mill, roll support, comprising central hub having wings which extend tangentially therefrom; and which are recessed to form guideways, bottoms of which incline downwardly toward hubs, and are apertured adjacent thereto, while their sides have vertical grooves formed therein; bearing blocks located in guideways, each having horizontal bore, tongues which fit in vertical grooves, and oil holes, one of which extends through top of block into bore, while other extends from bore through bottom of block and communicates with guideway of support; rolls having shafts which are journaled in bore of block, rolls having shoes with two grinding faces at angle to each other, in combination with chamber having central bore surrounded by oil cup, anular die having faces which coincide with faces of rolls, and shaft extending through bore, to which support is keyed, and means for revolving shaft and support.

METHOD OF TREATING REFRACTORY ORES.—No. 751,401; E. H. Miller, London, England.

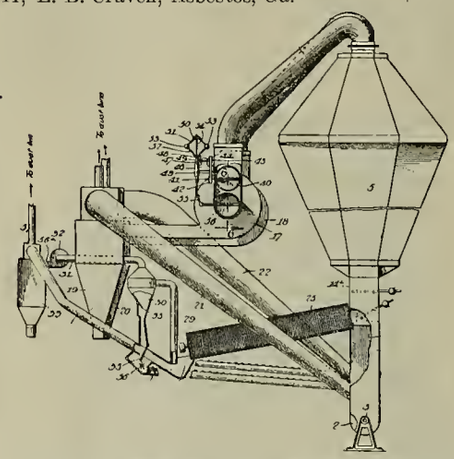
Process for treatment of refractory lead-zinc ores consisting in mixing ore with siliceous matter and pitch, with addition of lime according to silver value of ore, forming mixture into dry blocks, packing blocks in furnace with suitable air spaces, and sprinkling layers with lime and gradually raising temperature, whereby substantially whole zinc content of ore is converted into metallic zinc which distils over, and lead and silver contents of ore are also converted into metallic state in which state they are retained in residue in retort and recovered therefrom by melting out.

MINING DRILL FOR COAL OR ROCK.—No. 752,490; A. Walker, Whatcheer, Iowa.



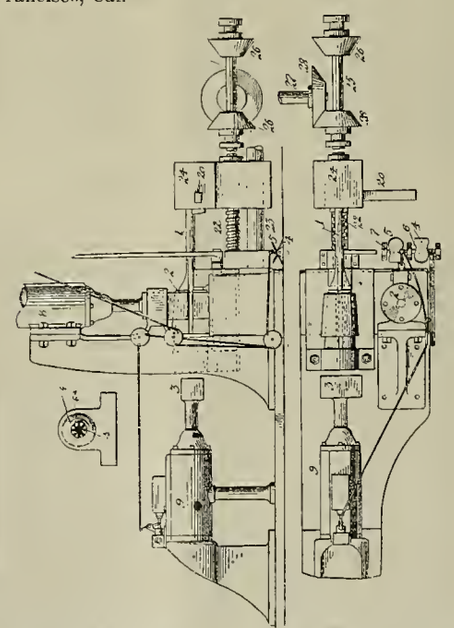
In drilling machine, combination with threaded drill rod, of boxing for drill comprising two semicylindrical sections hinged together along one edge, each provided centrally upon its interior with semiannular recess, sections being internally threaded on both sides of recesses, two recesses when boxing is closed registering and forming continuous annular recess for reception of lubricant, and threads ou two sections also registering to form continuous threads for engaging threaded drill rod.

REDUCING AND SEPARATING MACHINE.—No. 752,044; E. B. Craven, Asbestos, Ga.



A device of class described, comprising pair of reduction mills, separator having compartments connected with mills and subcompartments provided with discharge valves, partitions within compartments, movable deflectors at upper ends of partitions, stationary deflectors in upper part of separator chambers, means for inducing air currents through separator chambers and through fan casings, dust collectors receiving air currents and particles suspended therein from fan casings, and means for returning air currents from upper ends of dust collectors to reduction mills.

DRILL SHARPENER.—No. 752,026; J. L. Bryson, San Francisco, Cal.



In machine for described purpose, dolly comprising anvil, separated arms extending therefrom and having grooved ends, support for drill bits in line with free ends of arms, means for adjusting support relatively to arms, means for closing and releasing free ends of arms, and a hammer.

Mining Summary.

SPECIALLY COMPILED AND REPORTED FOR THE MINING AND SCIENTIFIC PRESS.

ALASKA.

The Carvey McNeer bench property in Nizina has been sold to H. V. Winchell. The group consists of thirteen bench claims on Rex and White gulches, for which $100,000 will be paid. He is also said to have taken over the holdings of the Chittateau Dev. Co. Equipment will be taken in via Valdez and work started the coming season.

ARIZONA.

Apache County.

Twenty-five miles northeast of St. Johns, C. W. Davis and A. Shreeve report finding three veins of coal—one 4 inches thick, one 6 inches and the other 4 feet—of coking quality. A company is being formed at St. Johns to develop it. When the railroad which is expected to go through that part of the country is built, the expense of getting the coal to market will be lessened.

Cochise County.

The diamond drill at the Wolverine & Arizona mine, near Bisbee, is in operation on the Broken Premise claim, towards the White Tail Deer ground, which adjoins the claims of the Wolverine & Arizona. The drill is in the 550-foot level in the main shaft. The management of the Wolverine & Arizona says the operation of the diamond drill will not interfere with other development work. Sinking the shaft and running drifts will continue.

The Commonwealth, at Pearce, has resumed work. They are running a drift on the seventh level and another drift east of the hoist. It is expected they will start twenty stamps next week. They are also taking out ore in the side of the cave.

H. C. McCreery, operating on the Copper Chief group of claims, Johnson district, near Wilcox, says work is progressing and he has opened a body of sulphide ore. The development work consists of a shaft down 200 feet and in ore. Two drifts have been run, one east and the other west. It is proposed to build a mill.

The Douglas Dispatch says two of the furnaces of the new Copper Queen smelter at Douglas will be blown in by March 1st.

Maricopa County.

(Special Correspondence). — W. Wadlington has put men to work on his mines in the Eagle Tail mountains. Until the recent rain there has been no water in those mountains for some time.

The Joplin claim in Vulture district, near Wickenburg, has been sold to R. S. Slusher of Phœnix. The ore carries lead and silver.

Wickenburg, Feb. 22.

Mohave County.

(Special Correspondence). — The Mossback mine in Silver Creek district, near Acme, above Needles, Cal., owned by C. H. Burlock et al of Los Angeles, Cal., has been bonded by S. M. Slocum, who has started development work. This group of three claims shows limestone cropping 300 feet in width. Burlock, in blasting out a place for tools, uncovered a calcspar ledge carrying values. This is being sunk on, and it is increasing in value and size. At present depth of 40 feet it is 14 feet wide and averages $9 per ton. He intends to sink 100 to 200 feet and then crosscut the ledge. Abundance of water can be had from 4 miles above and brought to camp by ditch.

The Black Mountain G. M. Co., under superintendence of A. I. Richardson, is doing considerable development work on its group.——Near Silver Creek spring on slope of Gold mountain is a ledge cropping for length of nine claims. The three eastern are held by M. Hawkins. The middle group is owned by R. J. Holmes, and 700 feet of work is done on it. In one tunnel 265 feet in on the ledge the ore is 12 feet in width and assays average of $32. The western group is owned by R. E. Zuver et al, and 500 feet of work has been done, with development work continuing. The ore is being sorted, sacked and stored. When the ore body has been blocked out stopes will be started and a mill built. Water is coming into the mine and may develop in sufficient quantity for mill purposes. Water can be developed at the spring which is 1 mile from the mine. The ledge, running 10 to 40 feet in width, cuts the country rock for nearly 3 miles in length. All the ravines running from it have been dry placered and stringers along the hillsides have been worked for pockets of ore for a number of years.

Needles, Feb. 23.

E. S. Osborne and C. W. Wardwell have taken over a group of mines near Parker. They have taken in supplies and have started work. The ores carry gold and copper values.

The Gold Roads mine, near Acme, continues regular shipments of bullion, sending out $42,000 in the first thirteen days of February. It is reported the management will put in electrical transmission lines from the railroad to operate the mines and mill and at the same time make changes in the reduction and handling of ores.

Santa Cruz County.

The Tolluride G. M. Co. has been incorporated at Negales by L. A. Teague, B. W. Haines, A. Cane, R. L. Logan and C. O'B. Reddin.

CALIFORNIA.

Butte County.

(Special Correspondence).—The Steifer M. Co. drift mines at Nimshew, owned and operated by Steifer Bros., will be equipped with machinery. They are preparing to put in electric power. The cemented gravel will be handled by a 10-stamp mill. P. B. Steifer is president and superintendent.

Work is progressing at the Magalia mine, near the Steifer M. Co. holdings.

Nimsbew, Feb. 24.

Oroville reports that the Feather river rose rapidly last week, owing to heavy rains. It is said there are 8 feet of snow in the mountains at La Porte, and that the rain which fell melted the snow rapidly. All the dredgers on the river shut down, the water being so high that it was not safe to continue dredging. At the Pennsylvania the water was up around the buildings. A portion of the Veatch tract, in the western part of Oroville, is covered with water to a depth of several feet. This is caused by the overflowing of the dredger pond at one of the boats.

Calaveras County.

It is reported a rich strike has been made in the Voinich mine, near Angels, being developed by Stockton men. The lead was struck at depth of 250 feet. G. Turner is president.

Del Norte County.

J. B. Crawford, manager of the Cleopatra group of copper mines in Diamond Creek district, near the Oregon-California line, south of Waldo, Or., reports work progressing. The district is reached by the Diamond Creek road from the Grant's Pass-Crescent City stage line. The development work at present is confined largely to the Ohio, at southern end of group. A tunnel that was driven in on the ledge is being retimbered. This tunnel taps the ledge at depth of 260 feet. It is a crosscut, and from this depth drifts are run both ways on the ledge. The Sidney, another claim of the Cleopatra group, is being developed by tunnel, which is in 400 feet, and will tap the main ore body at 250 feet farther.

El Dorado County.

At Omo Ranch (formerly Brownsville mining district) work is being done by the Alexander G. M. Co. on the Crystal group. They report last week having opened up another ore shoot in the main tunnel. The mill is running.——The Lady Edner will make a cleanup as soon as the weather permits.——G. Estey will resume work on the Whim mine this week.

Inyo County.

G. Montgomery et al. have started operations on the World Beater group of mines at Ballarat and will put in development and milling machinery.

Nevada County.

The old Badger mine at Grass Valley has been taken under option by U. P. Koenig for Milwaukee, Wis., men. The shaft will be cleaned out as well as the tunnels. The Badger has been idle for twenty years.

W. S. Gage, secretary of the Pesey G. M. Co., and Superintendent W. H. Bray are preparing to resume operations at the Posey mine, near Nevada City.

The mill at the Rose Hill mine, near Grass Valley, operating on the dump of ore, will be enlarged, says J. H. Spencer, part owner. This dump was regarded as waste rock when the mine was formerly worked.

Work has been started at the Seven-Thirty mine, near Grass Valley, clearing away the site for hoisting works and buildings for development of the mine, says Manager Root. The shaft has been cleaned out to the water level and while the buildings are being put up the shaft will be timbered from that point to the surface.

Placer County.

H. W. Morris, of San Francisco, has bought the Rawhide mine, near Shady Run, for $80,000, and will put in air compressors, drilling machines and other improvements.

At the Southern Cross mine in Humbug canyon, 4 miles from the Rawhide mine, near Shady Run, the 10-stamp mill, which is run by electricity, will be enlarged.

Plumas County.
